SEARLE DIAGNOSTIC

products for research

Mouse Theta Antisera
C3H anti AKR, AKR anti C3H
CBA anti AKR, AKR anti CBA

Cultured Human Lymphocytes
Available viable or frozen

Fluorescent Theta Antibody NEW PRODUCT
C3H anti AKR,
AKR anti C3H

Mouse Ia Antisera NEW PRODUCT
10 available

Ly – 4.2 Antiserum NEW PRODUCT
SWR x Balb/c anti B10D2

Mph – 1.2 Antiserum NEW PRODUCT
Mouse Peritoneal macrophage Alloantiserum

HLA Antisera*
36 types now available

H-2 Antisera
Derived from cross immunisations of mouse a, b, d, f and s genotypes

Tissue Typing Plates
Glass slide with acrylic support frame

Tissue Typing Medium NEW PRODUCT
Modified McCoy 5A

Sedimentation Reagent NEW PRODUCT
For lymphocyte separation

Anti-Lymphocyte Serum
Rat, Mouse and Human

Rat Alloantisera
Pvg anti Wag Wag anti Agus
Wag anti Pvg Agus anti Wag

*Not for diagnostic use in North America.

"Philips have put more improvements into their EM400 than you could possibly use"

Other electron microscope makers may tell you this.
Don't you believe it.
We have, in fact, made the EM 400 the world's finest electron microscope.
We've given you the cleanest high vacuum. Computer-memory-controlled image correction.
More accurate magnification and wider range.
Automated illumination/exposure.
Full display/print-out of operating conditions.
Better protection from vibration, stray fields and thermal effects.
Even more! Why?
To give you more information than you've ever had from your specimen.
To provide a solid base for your future electron optical system.
The EM 400 does this better than any other TEM.

Philips Industries
Electron Optics Department
Building TQIII-2
Eindhoven, The Netherlands

Proof! Seeing is believing!

☐ Send me further information on the superiority of the EM 400.
☐ Contact me for a personal demonstration, so I can see the difference for myself.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:
(i) only one reference number need be used if the reference is to several papers by identical authors,
(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use of the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v (1976).

Early presence of ribonucleoprotein antigen on surface of influenza virus-infected cells — *J. L. Virelizier, A. C. Allison, J. S. Oxford and G. C. Schild* 52
Infectious DNA from a whitefly-transmitted virus of *Phaseolus vulgaris* — *R. M. Goodman* 54
Biochemical characterisation of a serum thymic factor — *J.-F. Bach, M. Dardenne, J.-M. Pleau and J. Rosa* 55
Lymphocytes suppressing both immunoglobulin production and erythroid differentiation in hypogammaglobulinaemia — *S. D. Litwin and E. D. Zanjani* 57
Reduced rates of proteolysis in transformed cells — *J. M. Gunn, M. G. Clark, S. E. Knowles, M. F. Hopgood and F. J. Ballard* 58
Thermogenic defect in pre-obese *ob/ob* mice — *P. Trayburn, P. L. Thurlby and W. P. T. James* 60

INSTITUTE OF RADIOPHYSICS AND ELECTRONICS · LIBRARY C.U.

Announcing

Inorganic perspectives in biology and medicine

Managing Editors:
C.A. MCAULIFFE, UMIST, *P.O. Box 88, Manchester M601QD, U.K.* J. WEBB, *School of Mathematical and Physical Sciences, Murdoch University, Murdoch, Western Australia 6153, Australia.* P. MELIUS, *Auburn, Alabama, 36830, U.S.A.*

The area between inorganic chemistry and the biological sciences has attracted a great deal of attention during the last decade. The dialogue between the parent disciplines proved difficult in the absence of a mutually understandable "language".

Inorganic Perspectives in Biology and Medicine tries to bridge this gap by presenting review articles on the role of inorganic elements in biological (animal and plant) and medical systems, with both audiences in mind. As the journal emphasizes the biosystem rather than the inorganic species in isolation, it will not deal with model systems per se. In this sense *Inorganic Perspectives in Biology and Medicine* may be considered complementary to *Coordination Chemistry Reviews,* and for that very reason the Editors for the two journals will pursue a policy of active collaboration.

Editorial Board:
M.J. CLEARE, Reading, United Kingdom. J. JORDANOV, Strasbourg, France. M. KIRCHGESSNER, Freising, W. Germany. A.B.P. LEVER, Ontario, Canada. W. MERTZ, Beltsville, Maryland, U.S.A. J.M. PRATT, Johannesburg, South Africa. A. SANTOS-RUIZ, Madrid, Spain. B. SARKAR, Cambridge, United Kingdom. F.W. SUNDERMAN, Jr., Farmington, Connecticut, U.S.A. E.G. UNDERWOOD, Wembley, Western Australia. B. VALLEE, Boston, Massachusetts, U.S.A. M.R.C. WINTER, Macclesfield, United Kingdom. H.B. GRAY, Pasedena, California, U.S.A. L. KOPITO, Cambridge, Massachusetts, U.S.A.

Specimen copies are available upon request from the Publisher.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors,

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish. *Nature's* publishing policy is outlined in **258**, 1 (1975) and **264**, v (1976).

Isolation of amitrole-degrading bacteria	*E. F. Campacci, P. B. New and Y. T. Tchan*	164
Frequency of heavy-metal resistance in bacteria from inpatients in Japan	*H. Nakahara, T. Ishikawa, Y. Sarai, I. Kondo and S. Mitsuhashi*	165
Permanent segmental interchange complex in the termite, *Incisitermes schwarzi*	*R. M. Syren and P. Luykx*	167
Parallel variation at an enzyme locus in sibling species of field crickets	*R. G. Harrison*	168
Possible role for acetylcholine in aggregation centre spacing in *Polysphondylium violaceum*	*M. A. Clark*	170
Frequency of mating-type switching in homothallic fission yeast	*R. Egel*	172
Rapid, chloramphenicol-resistant, activation of membrane electron transport on germination of *Bacillus* spores	*B. J. Wilkinson, D. J. Ellar, I. R. Scott and M. A. Koncewicz*	174
Solubilisation of atropine-binding material from brain	*S. Carson, S. Godwin, M. Massoulie and G. Kato*	176
Calcium levels in the brain underlie temperature control during exercise in the primate	*R. D. Myers, C. V. Gisolfi and F. Mora*	178
Chorionic membrane as an extra-adrenal source of foetal cortisol in human amniotic fluid	*B. E. P. Murphy*	179
Spectrin is absent in various tissue culture cells	*G. Hiller and K. Weber*	181
Precocious development of foetal glucuronidating enzymes induced by glucocorticoids in culture and *in utero*	*G. J. Wishart and G. J. Dutton*	183
Liver protein metabolism response to cold in genetically obese (*ob/ob*) mice	*B. G. Miller, R. F. Grimble and T. G. Taylor*	184
Contractile activation in slow and twitch muscle fibres of the frog	*W. F. Gilly and C. S. Hui*	186

SEARLE DIAGNOSTIC

products for research

Mouse Theta Antisera
C3H anti AKR, AKR anti C3H
CBA anti AKR, AKR anti CBA

Cultured Human Lymphocytes
Available viable or frozen

Fluorescent Theta Antibody
NEW PRODUCT
C3H anti AKR,
AKR anti C3H

Mouse Ia Antisera
NEW PRODUCT
10 available

Ly – 4.2 Antiserum
NEW PRODUCT
SWR x Balb/c anti B10D2

Mph – 1.2 Antiserum
NEW PRODUCT
Mouse Peritoneal macrophage
Alloantiserum

HLA Antisera*
36 types now available

H-2 Antisera
Derived from cross immunisations
of mouse a, b, d, f and s genotypes

Tissue Typing Plates
Glass slide with acrylic
support frame

Tissue Typing Medium
NEW PRODUCT
Modified McCoy 5A

Sedimentation Reagent
NEW PRODUCT
For lymphocyte separation

Anti-Lymphocyte Serum
Rat, Mouse and Human

Rat Alloantisera
Pvg anti Wag
Wag anti Pvg
Wag anti Agus
Agus anti Wag

*Not for diagnostic use in North America.

NEWS AND VIEWS

Ebela virus/Trypanosome antigen/Thalassaemia detection/ Geomagnetic polarity/Earthquake prediction/Optical fibres/ Short-range nuclear forces 217

REVIEW ARTICLE

Some recent developments in remote sensing — *P. Schagen* 223

ARTICLES

The observability of possible atmospheric removal processes for chlorfluorocarbons 11 and 12 — *R. J. Gelinas, D. K. Hall and R. G. Nelson* 229
Direct demonstration of β-globin mRNA in homozygous Ferrara β_0-thalassaemia patients — *S. Ottolenghi, P. Comi, B. Giglioni, R. Williamson, G. Vullo and F. Conconi* 231
5′-Terminal structure and mRNA stability — *Y. Furuichi, A. LaFiandra and A. J. Shatkin* 235

LETTERS TO NATURE

Radio counterpart of the X-ray source 3U0901 −09 — *R. Wielebinski, H. Waldthausen, P. P. Kronberg and C. G. T. Haslam* 239
Spectroscopic evidence for interstellar grain clumps in meteoritic inclusions — *A. Sakata, N. Nakagawa, T. Iguchi, S. Isobe, M. Morimoto, F. Hoyle and N. C. Wickramasinghe* 241
Prebiotic molecules and interstellar grain clumps — *F. Hoyle and N. C. Wickramasinghe* 241
Gravitational radiation detector observations in 1973 and 1974 — *J. Weber* 243
Radiometric measurement of stratospheric HCl — *J. R. Eyre and H. K. Roscoe* 243
Mantle helium in the Red Sea brines — *J. E. Lupton, R. F. Weiss and H. Craig* 244
The continental crust north-east of Newfoundland and its ancestral relationship to the Charlie Fracture Zone — *R. T. Haworth* 246
Preliminary palaeomagnetic results from Makapansgat and Swartkrans — *A. Brock, P. L. McFadden and T. C. Partridge* 249
New aspects of Middle Palaeolithic variability in western Europe — *N. Rolland* 251
'Modern' lizard from the Upper Triassic of China — *R. L. Carroll and P. M. Galton* 252
Adaptive reduction in permeability of avian eggshells to water vapour at high altitudes — *G. C. Packard, P. R. Sotherland and M. J. Packard* 255
Virus-like particles in the nematode *Romanomermis culicivorax* (Mermithidae) — *G. O. Poinar and R. Hess* 256
Nitrogenase activity of endophyte suspensions derived from root nodules of *Alnus*, *Hippophae* and *Shepherdia Myrica* spp. — *J. van Straten, A. D. L. Akkermans and W. Roelofsen* 257

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors,

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,** 1 (1975) and **264,** v (1976).

Adenylate cylase activity oscillations as signals for cell aggregation in *Dictyostelium discoideum*	*W. Roos, C. Scheidegger and G. Gerisch*	259
Bacterial tumble regulator may be inactivated by methylation	*J-M. Frère*	261
Mucosal penetrability enhanced by serum-derived antibodies	*P. Brandtzaeg and K. Tolo*	262
Endplate current fluctuations reveal only one channel type at frog neuromuscular junction	*V. E. Dionne and R. L. Ruff*	263
Selective activation of sympathetic ganglia in young spontaneously hypertensive rats	*K. Nakamura and K. Nakamura*	265
Colour-coding properties of sustained and transient channels in human vision	*D. J. Tolhurst*	266
Solubilisation and partial purification of auxin-binding sites of corn membranes	*M. A. Venis*	268
Relationship between amount of Epstein–Barr virus-determined nuclear antigen per cell and number of EBV–DNA copies per cell	*I. Ernberg, M. Andersson-Anvret, G. Klein, L. Lundin and D. Killander*	269
Proton pump coupled to cytochrome *c* oxidase in mitochondria	*M. K. F. Wikstrom*	271
Non-allelic variants of histones 2a, 2b and 3 in mammals	*S. G. Franklin and A. Zweidler*	273
Formation of amino acids from elemental carbon by contact glow discharge electrolysis	*H. Harada and S. Suzuki*	275
Enzyme hydration may explain catalytic efficiency differences among lactate dehydrogenase homologues	*G. N. Somero and P. S. Low*	276
Calculated forbidden band gap in periodic protein models indicating them to be insulators	*M. Kertész, J. Koller and A. Azman*	278

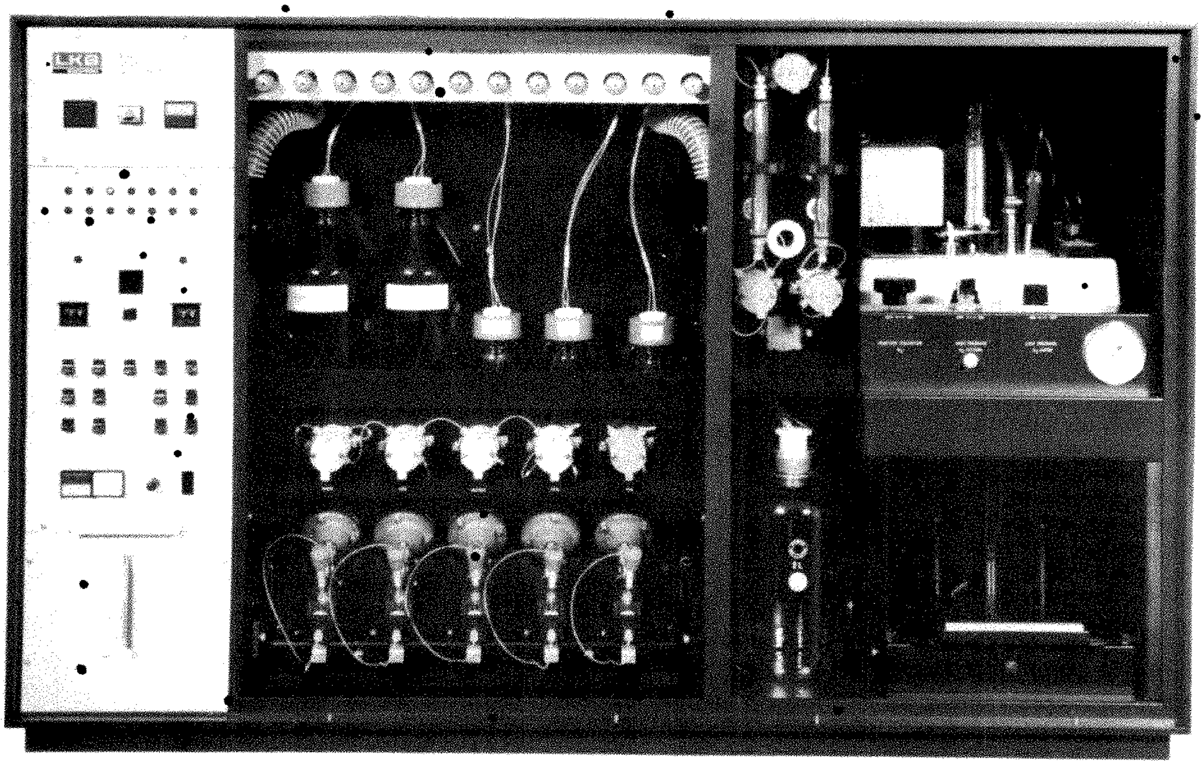
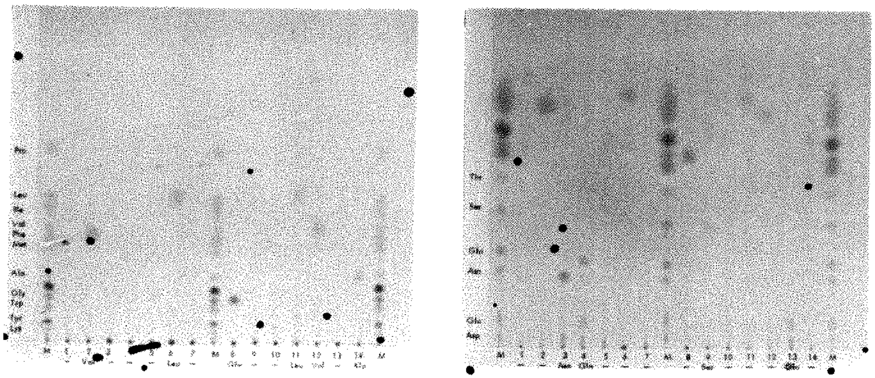
OURS SEQUENTIALLY!



e LKB 4020·Solid-Phase Sequencer provides information on the
iino-acid sequence of proteins or peptides using the solid-phase
nan technique and features:-

Single and Dual Column Operation	for fast sample throughput.
Versatile Pumping System	allows wide variety of programmes and applications.
Easy-to-use Punched Card Programmer	makes it easier for user to prepare specialised programmes.
Operator and Sample Protection Systems	protect against operational errors.
Micro-sequencing Capability	allows use of radio-active tracer when minimal sample available.



L.C. plates of first 14 residues of Insulin B chain sequenced on LKB4020

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors,

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, 11 Nov.v (1976).

The role of chemotaxis in the ecology of bacterial pathogens of mucosal surfaces — *B. Allweiss, J. Dostal, K. E. Carey, T. F. Edwards and R. Freter* 448
Helical shape and wall synthesis in a bacterium — *M. J. Tilby* 450
Neoplastic transformation of hamster embryo cells irradiated *in utero* and assayed *in vitro* — *C. Borek, C. Pain and H. Mason* 452
Local inhibition of centripetal particle transport where LETS protein patterns appear on 3T3 cells — *G. Albrecht-Buehler and L. B. Chen* 454
Complement enhances antiviral antibody-dependent cell cytotoxicity — *B. T. Rouse, A. S. Grewal and L. A. Babiuk* 456

Pharmacia
Peristaltic Pump P-3

A compact pump electronically controlled for constant liquid flows in chromatography and gradient formation

You can

- obtain three different flow rates at the same time through the three individually tensioned pumping channels
- change tubes in seconds with the snap-in cassette
- forget about pulsation thanks to the large driven rollers
- rely on a constant motor speed, electronically compensated for load and temperature
- use any flow rate between 0.6 and 400 ml/h per channel with the same gear box
- reverse the flow instantly
- push for maximum flow and clear pump lines rapidly

as one flask said to another flask...

"This Luckham Rotatest certainly shakes you up!"

A new development of the Rotatest enabling the operator to select continuous rotation in one direction or a reciprocating rotation of about 12–60 seconds according to requirements in both clockwise and anti-clockwise directions with a "dwell" period between each change of 1 to 2 seconds.

Variable speed as the Rotatest R/100. The Rotatest orbital shaker has been specifically designed to provide smooth equal blending and mixing by horizontal rotary motion. Illustrated here is the R/100 AR which will hold 6 conical flasks of both 250 ml and 500 ml sizes.

Crystal and molecular structure of a 'hexa-host' inclusion compound — *D. D. MacNicol, A. D. U. Hardy and D. R. Wilson* 611
Effect of magnetic field on reduction of iron oxides: magnetite and wüstite — *M. W. Rowe, S. M. Lake and R. Fanick* 612
Computer simulation and statistical geometric model for contacts in binary random two-dimensional disk packings — *J. Dodds and H. Kuno* 614
Gravity in Zambia — *I. M. Cowan and H. N. Pollack* 615
Electrical conductivity and tectonics of Scotland — *V. R. S. Hutton, J. M. Sik and D. I. Gough* 617
Tectonic and sedimentary significance of Cretaceous Tekenika Beds of Tierra del Fuego — *R. H. Dott, Jr. R. D. Winn, Jr. M. J. DeWit and R. L. Bruhn* 620
Rapid removal of plutonium from the oceanic surface layer by zooplankton faecal pellets — *J. J. W. Higgo, R. D. Cherry, M. Heyraud and S. W. Fowler* 623
Growth rate and longevity in *Drosophila melanogaster* and *Tribolium castaneum* — *F. A. Lints and M. H. Soliman* 624
Albedo measurement for remote sensing of crop yields — *S. B. Idso, R. J. Reginato and R. D. Jackson* 625
Experimental transmission of *Leishmania chagasi*, causative agent of neotropical visceral leishmaniasis, by the sandfly *Lutzomyia longipalpis* — *R. Lainson, R. D. Ward and J. J. Shaw* 628
Conjugal transfer of R plasmids in *Neisseria gonorrhoeae* — *M. Roberts and S. Falkow* 630
Thymus metabolises progesterone—possible enzymatic marker for T lymphocytes — *Y. Weinstein, H. R. Lindner and B. Eckstein* 632
Evidence for control of complement receptor rosette-forming cells by α and β-adrenergic agents — *M. Ito, F. Sless and M. V. Parrott* 633
Response of mesencephalic and hypothalamic dopamine neurones to α-MSH: mediated by area postrema — *W. Lichtensteiger and R. Lienhart* 635
Possible relationship between glial cells, dopamine and the effects of antipsychotic drugs — *F. A. Henn, D. J. Anderson and A. Sellström* 637

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:
(i) only one reference number need be used if the reference is to several papers by identical authors,
(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, *v*, 11 Nov. (1976).

Human prolactin responses to neuroleptic drugs correlate with antischizophrenic potency — *G. Langer, E. J. Sachar, P. H. Gruen and F. S. Halpern* 639
Defective dopaminergic regulation of prolactin secretion in a rat pituitary tumour cell line — *W. B. Malarkey, J. Groshong and G. E. Milo* 640
Prolactin–progesterone antagonism in self regulation of prolactin receptors in the mammary gland — *J. Djiane and P. Durand* 641
Alteration in glucocorticoid binding site number during the cell cycle in HeLa cells — *J. A. Cidlowski and G. A. Michaels* 643
Biological activities of prostaglandin analogues and metabolites on bone in organ culture — *A. H. Tashjian, Jr, J. E. Tice and K. Sides* 645
Inhibition of masculine differentiation in male offspring of rabbits actively immunised against testosterone before pregnancy — *F. Bidlingmaier, D. Knorr and F. Neumann* 647
Vitamin A deprivation and *Drosophila* photopigments — *W. A. Harris, D. F. Ready, E. D. Lipson, A. J. Hudspeth and W. S. Stark* 648
Storage of cannabinoids by *Arctia caja* and *Zonocerus elegans* fed on chemically distinct strains of *Cannabis sativa* — *M. Rothschild, M. G. Rowan and J. W. Fairbairn* 650
Nature of recombinants produced by the RecBC and the RecF pathways in *Escherichia coli* — *S. K. Mahajan and A. R. Datta* 652
High-LET radiations induce a large proportion of non-rejoining DNA breaks — *M. A. Ritter, J. E. Cleaver and C. A. Tobias* 653
Electrical demonstration of rapid light-induced conformational changes in bacteriorhodopsin — *H.-W. Trissl and M. Montal* 655
Catalytic effect of nitrosophenols on *N*-nitrosamine formation — *R. Davies and D. J. McWeeney* 657

Erratum

Cover picture

A photograph (6½° × 6½°) of the Vela Supernova remnant, taken on the U.K. Schmidt Telescope at Siding Spring. A mosaic Hα filter, designed by John Meaburn, was used.

Optical pulses from the Vela pulsar are reported on page 692. See also page 676.

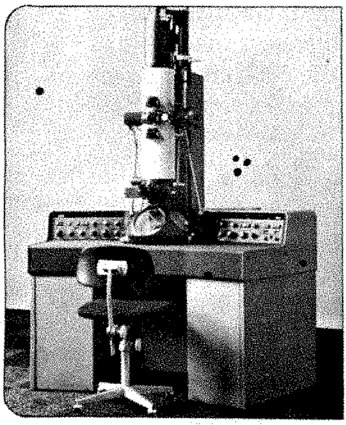
"Adding a bigger pump will give you a clean high vacuum as good as Philips' EM 400"



That's what some electron microscope makers are saying.
They're wrong.
We can prove it.
Designing an electron microscope isn't like decorating a Christmas tree.
What matters is what you begin with.
Not what you add on afterwards.
Protecting your specimen from contamination and erosion (what clean high vacuum is for) demands more than cutting down Torr values.
You've got to cut hydrocarbon and water vapour partial pressures.
This means becoming clean high vacuum specialists.
We have.
That's one reason why the EM 400 gives you more information from your specimen than you've ever had before.
Why you can't afford "patch-up" solutions!

Proof!

Seeing is believing!

☐ Send me your new bulletin featuring "Clean vacuum systems for electron microscopes."
☐ Send me further information on the EM 400.
☐ Contact me for a personal demonstration.

Why is a beautiful hotel like the Pulitzer featured in a magazine like this?

Guess!

Even a scientist needs to relax

The four star Pulitzer is located along one of Amsterdam's most famous canals in the heart of the city. 17 historic buildings were completely restored to their original beauty and combined to house 175 guest rooms all with modern facilities. Graced with beams and natural brick walls, each room reflects a rustic charm not found elsewhere in Amsterdam.

You'll find a cozy bar to relax after a busy day. A restaurant which serves delicious Dutch and French food. And keep in mind that the Pulitzer has private meeting facilities up to 60 persons.

So when you're planning a trip to Amsterdam, remember the Pulitzer.

For additional information and instant free reservations: Call Nicholas Lawson Ltd. London: 01/4917431, telex 23189.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors,

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v, 11 Nov. (1976).

3 March 1977

The law moves in

A MEETING of the American Association for the Advancement of Science (AAAS) is a hard time for journalists. Somehow one has to find a theme behind it all; not just the anonymous title adopted for this year's gathering in Denver —'Science and Change: Hopes and Dilemmas'—but some ground base on top of which runs the counterpoint of corridor and coffee-shop conversation.

It isn't an easy task. First, there is the preposterous proliferation of sessions about which almost everyone seems to complain. At any one time you have to choose amongst weather modification, Mars, everyday physics, solar energy, energy in the Rockies, polar research, food pests, desert dust, behavioural research, organ transplants, early experience in primates, appropriate technology, cognition, minorities in science, limits to growth, information policy, religious minorities, systems research and the problems of a science academy. Second, scientists tend (as at the British Association) to drop in, cast their pearls and drop out. With some honourable exceptions this leaves little time for long conversations. Third, the rhetoric doesn't help— what do administrators really mean when they talk about addressing the issues through a hopefully ongoing soft-failure mode of evaluation, and assessment within a prioritised problem-solving environment?

And yet there was at least one theme to emerge from it all, and that was the increasing attention that lawyers are paying to the scientific and technological scene. Some of this attention has been in the field of human rights, where the remarkable action of President Carter in writing to Dr Sakharov has raised many hopes amongst both scientists and lawyers. But scientists and lawyers don't always find themselves fighting on the same sides, and several sessions were devoted to the difficult issues of scientific freedom and responsibility, not just in the abstract but with pressing matters right to hand. The Governor of Colorado, Richard Lamm, who came to power not by the conventional political route but through an environmental concern which captured the state's imagination, put the problem remarkably succinctly in a public lecture. He had, he remarked, been surprised to see a session entitled 'Science: the Key to our Political Future'. (He would have been even more surprised if he had attended the session by some of the let-the-scientists-get-on-with-it views expressed.) For Governor Lamm a more appropriate title would have been 'Politics: the Key to our Scientific Future'. And the theme that science and technology must expect to be increasingly circumscribed by politicians, the courts and public opinion was widely taken up.

It is not only the recombinant DNA question which has aroused some new concerns. The legal position of those working on earthquake prediction is likely to be questioned before long in the courts. The recent Teton Dam disaster in Idaho, subject of an excellent documentary shown, coincidentally, on television during the conference, raises further questions of how much responsibility the scientist can bear for a project that fails. But the most striking example at present was on the AAAS's doorstep in Colorado —weather modification. The western United States is in the grips of a drought and there is little snow on the mountains to provide relief this spring. The Denver Hilton was doing its bit, it announced, by not providing iced water for customers in its restaurants unless they specifically asked for it. A golden opportunity for rain-makers to show their simple yet still highly debated skills. One such person boldly distributed his advertisements around the conference, 'for rain in only 6 days, anywhere, call . . . '. But things are becoming less simple. A whole day was devoted to a scientists/lawyers meeting on the law of weather modification, and the very same day the newspapers announced that if Washington state starts cloud-seeding, its neighbour, Idaho, will go to law to stop it.

There is little doubt that the law in the United States contains many as yet unexplored pitfalls for the scientist. There is a crucial distinction between speech and action in the constitution, which projects (in the most lurid example) the man who curses the flag but not the man who burns it. Likewise scientists seem to have the right to write, say and publish fairly freely, but what they do has no similar protection. The opposition to scientists is bound to grow— one honoured alumna of the University of Colorado, Boulder, told the local newspaper, 'I had a fairly competent position in science and felt impotent to do anything about the directions it was taking. As an attorney, I have a much better shot at controlling what they're doing than I had on the inside'. Scientists had better start facing these questions —not, one hopes, from a guild mentality, nor from the exaggerated stance heard at the conference that all science is being threatened, but simply because a good working relationship with lawyers is going to be necessary for science to flourish in the future.

Several people commented almost nostalgically that AAAS had been the quietest for years. No tomatoes thrown, no bitter squabbling, no police being called in. These days the police have been replaced by lawyers. □

Heading for harmony?

The debate prompted by genetic manipulation developments is intensifying in Europe. **Chris Sherwell** reports

IN PARIS on Tuesday a committee gathered quietly for its routine monthly meeting to discuss research involving genetic manipulation using recombinant DNA technology. In Brussels last Thursday another committee lodged deep in the labyrinth of the European Commission of the EEC met to discuss the same subject. On Thursday of this week Britain's equivalent body gathers for its own regular monthly session. Within the next week a commission on genetic manipulation in the Netherlands is expected to report its long-awaited findings. And on 15 March a new and potentially crucial group within the European Science Foundation (ESF) convenes its first meeting in Strasbourg.

Plainly, the pace of developments relating to recombinant DNA research in Europe has quickened. The debate is now consuming the time of government officials, science administrators and molecular biologists in at least nine different countries and no less than five international organisations. Indeed, the aforementioned meetings are but the tip of an enormous iceberg, and if activity is symptomatic of decisiveness, the energy now being spent discussing the subject ought inevitably to produce results. For those researchers actually wanting to do the work, however, it has meant long periods of delay, uncertainty and confusion.

The debate itself stems from the development over three years ago of elegant new genetic engineering techniques, the implications of which prompted widespread concern. This spawned the growth of guidelines, specifying conditions under which various types of experiment using the techniques should be done, and the growth of committees to administer them. The result is that the issue has spread well beyond the bounds of the research community immediately involved.

In the United States for example, where the pace has been hottest, the debates freest and public involvement greatest, the National Institutes of Health (NIH) finally published a complex set of guidelines last June. Failure to broaden these voluntary controls now threatens legislation to make them stick (see box), a development which could complicate the European debate.

So far the European debate has proceeded unsensationally, mostly at the national level; progress is varied. International discussions have gone quietly ahead, both informally among individuals and formally through those bodies which have perceived a role for themselves. The chances of them continuing without rancour could diminish, however, particularly if national differences emerge strongly in certain international forums.

Country catalogue

Most European countries have in fact trodden broadly similar paths. The examples of the United States and Britain have been important, the latter adding a new word to the English vocabulary: 'geemag'. The Genetic Manipulation Advisory Group (GMAG) was established in Britain last year following recommendations from the Williams working party on genetic manipulation.

Precautions contained in the Williams guidelines, like those in the NIH guidelines, involve both physical and biological containment. The standards of physical containment are more strict under Williams, however, while biological containment receives greater emphasis in the NIH guidelines. Among other differences, the NIH guidelines provide an extensive list of experiments and appropriate containment measures; under Williams GMAG decides matters case by case. GMAG itself had early problems over trade union representation, but later began business and by this week was meeting again (see box).

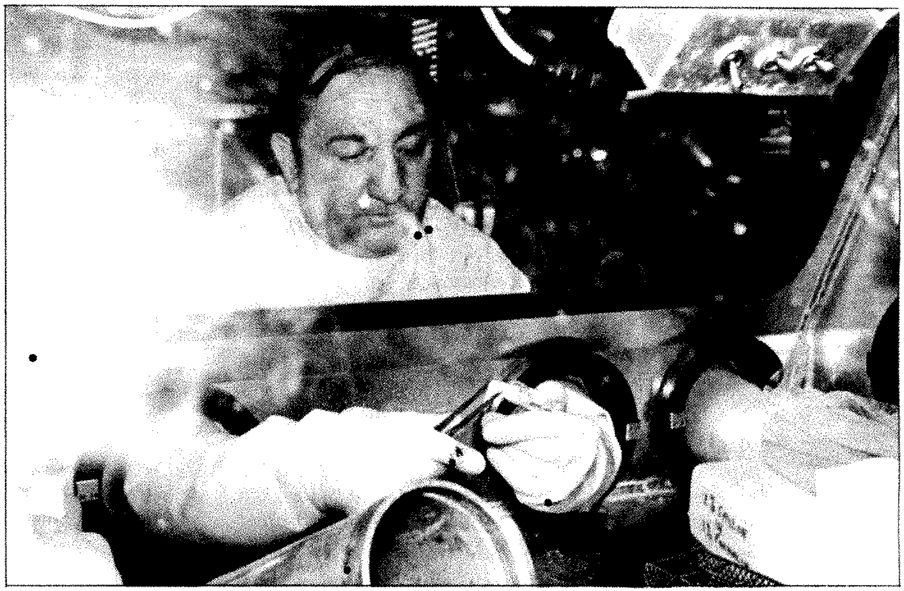
At least eight other countries in Europe have sought to involve themselves in the same sort of process.

France. In France two committees are directly involved. One, called an 'ethics committee' and having under 10 members, meets spasmodically to discuss the whole subject of genetic manipulation. The other, known as the *Commission de Controle*, was set up in 1975 under the auspices of France's main research body, the *Delegation Générale de la Recherche Scientifique et Technique* (DGRST). It has a membership of about a dozen, most of them with interests in recombinant DNA and related research. Industry and trade unions are not directly involved, though this could change; both are evidently prepared to abide by the *Commission* line.

The *Commission* meets regularly once a month to assess the conditions under which experiments in France are to be performed. It began by using the Asilomar guidelines, the product of the Asilomar conference in California in 1975, and subsequently used the NIH guidelines. More recently it has used both the Williams and NIH guidelines.

Over a period of some 18 months it has considered some 50 applications. Less than 10% have involved the more stringent containment conditions equivalent to the P3 and P4 categories of the NIH guidelines. The number of facilities in France which could now provide such containment is no more than a couple, and those would probably be at the P3 level.

Germany. The more fretful search for West German guidelines has produced four drafts, the latest of which was due to be distributed by the end of February, with the hope of producing a final draft by the spring. The government department involved, the Ministry of Research and Technology (BMFT), took over after a somewhat unsuccessful start under the German Research Council (DFG) using NIH guidelines.



Topix

Physical containment at Porton

The new national guidelines are expected to follow much the same lines as the NIH and Williams precedents. There will probably be an equivalent to Britain's GMAG with mixed representation. Guidelines will be voluntary, and it is hoped that industry, for the inclusion of which there are apparently no immediate plans, will follow them. There are no national P4 facilities in Germany, and few that would qualify as P3 facilities.

Switzerland. The Swiss Academy of Medical Sciences created a standing committee known as the Commission on Experimental Genetics. Headed by Werner Arber, Professor of Microbiology at the University of Basel, it has a membership of about a dozen, consisting of experts in the field and government officials from the health and science and technology ministries. Industry is ostensibly as keen as the universities to see controls implemented, and is represented on the Commission.

The Commission decided recently to follow the NIH guidelines, but this could still change in the future. It has been agreed with government agencies that no legislation is necessary. Researchers applying to the Swiss grant-giving body (*Suisse National Fonds*, SNF) and supplying relevant details would go before the Commission only when the SNF is unhappy; but they will probably be invited to register their work.

Sweden. An 11-man "committee concerning research with recombinant DNA" was set up last spring under the auspices of the Natural Science Research Council (NFR), the Medical Research Council (MFR) and the Swedish Cancer Society (RmC). Its chairman, Professor Peter Reichard of the Karolinska Institute, is the appointee on the committee of the NFR, which also appoints two lay representatives—in this case two MPs. The MFR, RmC, the Council for Forestry and Agricultural Research, the Board of Health and Welfare and the Association for the Pharmaceutical Industry each appoint one member; one member jointly represents the Academy of Sciences and the Academy of Engineering Sciences, another jointly represents the National Defence Research Institute and the Board for Technical Development; the Central Organisation for Salaried Employees appoints a representative for technical staff.

The committee will help granting agencies and government authorities to determine safety conditions for the experiments which they fund, and will probably work in the private sector as well. The committee will also advise researchers over safety precautions and help in risk classification, for which a working group has just been appointed. Researchers will be expected to submit experimental protocols to national advisory committees, which are responsible for specifying the containment measures. The containment procedures proposed are those of Williams, but experiments prohibited under the NIH guidelines, it is suggested, should not be carried out. Local safety committees would be responsible for supervising the measures.

So far the committee has received no applications and no recombinant DNA work is proceeding. The only group in Sweden which has worked in the field is at Uppsala under Professor Lennart Philipson, the MFR's appointee on the committee. His work is in abeyance, and he has yet to submit an application. The group has applied to have two new P3 laboratories built, but finance for these is not yet assured.

Denmark. Denmark has two committees. One, headed by Dr Kjeld Marcker from Aarhus, is an ad hoc committee established by the country's research council. It is examining work being done in Denmark and hopes to decide by the summer whether there ought to be a special research programme. The other is a Committee of Registration with 10 members representing research councils and industry but not trade unions. Its concern is with safety aspects, and it has been operating only a few months. The precise course it follows depends on the outcome of the first committee's work.

Holland. In January of last year, after consultation between the Royal Dutch Academy of Science and the National Health Council on the one hand, and the Ministry of Education and Science and the Ministry of Health on the other, a "Commission on Genetic Manipulation" was formed consisting of experts in the field and chaired by Professor Bootsma of Erasmus University, Rotterdam.

Its task was to compile an inventory of recombinant DNA research being done in the country and to advise laboratories on safeguards and the authorities on controls. The commission is expected to report its findings within the next two weeks, but there are differences of view about whether these should actually be published. The Dutch began by opting for the NIH guidelines but then switched to the Williams guidelines; now, however, it seems possible that national guidelines will be proposed which are more strict than either.

So far industry has not shown any public interest in the guidelines. Applications have come for six projects, from four universities. Three have come from the University of Amsterdam, and one from the Free University of Amsterdam, the University of Leiden and the University of Groningen.

Israel. A committee of the Israel Academy of Sciences and Humanities, chaired by Professor Leo Sachs of the Weizmann Institute, has recommended the establishment of a national safety committee for recombinant DNA research and of special safety committees at universities and research centres.

Legislation for US?

Legislation to control recombinant DNA research in the United States, a prospect which clearly concerns many scientists, is now considered inevitable. Bills have already been introduced into Congress, and in the next few weeks a committee consisting of officials from a number of federal agencies is expected to draft legislation to be submitted to Congress with the backing of the Carter Administration.

The Administration is reluctantly being pushed into drafting its own bill because if it doesn't, it will invite the prospect of harsher legislation and inconsistent local controls on recombinant DNA research. At present, the only formal controls on recombinant DNA research in the United States are guidelines issued last June by the National Institutes of Health (NIH), but they apply only to research supported by the federal government, and they are not backed by any enforcement or monitoring mechanism. Industry is not bound by any regulations.

Those apparent weaknesses in the present approach have prompted several state and local governments to consider adopting their own regulations on recombinant DNA research, and the fact that industrial research is not regulated at all has caused considerable public concern. Consequently, an inter-agency committee was established late last year under the chairmanship of NIH Director Donald Fredrickson to examine ways to extend the NIH guidelines to cover all recombinant DNA research in the United States. The committee has tentatively decided that no existing federal law can be used to extend and enforce the guidelines, and that new legislation is required.

That tentative conclusion was conveyed by Fredrickson last week to a group of prominent scientists and university administrators which met at NIH. Though Fredrickson repeatedly noted that no decision has been reached on the substance of the Administration's bill, it would almost certainly be designed simply to turn the NIH guidelines into enforceable regulations. It is also likely to include a clause pre-empting state and local regulations in an effort to ensure that regulations are uniform throughout the United States. It is not clear which agency would do the enforcing—clearly NIH wouldn't want to be in the position of supporting and regulating the research—but the likelihood is that the Center for Disease Control would be given the responsibility.

Colin Norman

The local committees would recommend appropriate safety precautions for every research proposal and then pass the matter to the national body, which has the final word.

The Academy decided that Israeli researchers would in general follow the NIH guidelines but would take into consideration recommendations from other bodies.

International catalogue

For Europe's researchers, worry as well as confusion is the product of the growing involvement of an increasing number of international bodies. But the important issue—whether or not there should be harmonisation of guidelines—already seems settled. There were benefits in allowing each country to follow its own path and arrive at its own conclusions, but different precautions in different countries threatened to encourage a concentration of researchers, so harmonisation looked preferable.

Moreover, with the subject a matter for public debate, there was the possibility that if one country applied more stringent controls than another, the difference itself could become an issue. Harmonisation could pose problems, though, if US researchers are faced with legally enforced regulations and there is public pressure for similar regulations in Europe. Creating a disinterested peer group competent to judge colleagues' work could be difficult enough without the added (if necessary) complication of drafting and enforcing legislation.

The case for harmonisation does not, however, solve the problem of which body has the authority to encourage the move towards it. A look at the organisations involved reveals the difficulty.

The World Health Organisation (WHO). The WHO has two bodies actively involved, the WHO Special Programme on Safety Measures in Microbiology and the WHO Environmental Programme. Being global and not confined to Europe, and concerned with the public health and safety aspects of the research, the WHO interest is peripheral as yet, although it has begun consultations, with, for example, Professor S. W. Glover, chairman of the International Microbial Genetics Commission, which has a genetic engineering sub-group.

The International Council of Scientific Unions (ICSU). ICSU has recently created a sub-committee known as COGENE, headed by the US microbiologist Bill Whelan. Its first official meeting is in Paris at the end of May. Because it too is part of a global agency, and because it represents international commissions in various disciplines more than national councils, ICSU can acquire an important role outside North America and Western Europe.

It can, for example, involve the East European countries and also the USSR, which is apparently keen to participate in the research under agreed guidelines—the USSR has a committee under Professor Bayev which hopes to produce its own guidelines by the middle of the year. ICSU can also involve important Third World countries, such as India and Nigeria, which cannot be prevented from pursuing the research but which might participate in any programme organised by ICSU on their behalf to help ensure that they take the necessary precautions.

The European Molecular Biology Organisation (EMBO). EMBO is based at Heidelberg, where a P4 facility for international use is under construction.

Britain's GMAG gets going

BRITAIN'S Genetic Manipulation Advisory Group (GMAG) has already given outline approval to more than half a dozen experiments, including one that requires the highest level of containment. For the present, however, the only place where such an experiment can be carried out is Porton, a Ministry of Defence establishment whose future is under scrutiny.

GMAG meets monthly to consider proposals for genetic manipulation experiments which, while awaiting a legal definition, are taken to refer to those in which restriction enzyme fragments of nucleic acids are recombined with the genomes of other organisms in which they are capable of propagation. GMAG's chairman is Sir Gordon Wolstenholme; it has 19 members, of whom only three have a direct interest in recombinant DNA research. Most of the others are biological scientists, but there are four union representatives and two non-scientific academics.

It is GMAG's task to consider any proposals and to state its objections, if any. Proposals (25 copies) are submitted on a formidable form on which full details of the protocol, personnel and facilities have to be provided along with information regarding local safety committees, biological safety officers, medical officers and health monitoring schemes. Proposed experiments fall into four categories, depending on the associated hazards. It is up to the proposers to categorise their own experiments but up to GMAG to ascertain whether the relevant requirements are satisfied.

In the case of the two categories (III and IV) that represent the greatest hazards, GMAG has to carry out a site inspection of the facilities. This they have already done for the category III facility at the MRC Mammalian Genome Unit in Edinburgh. Professor Peter Walker of that unit expresses himself well satisfied with the visit and its outcome which, pending attention to a few minor problems, should give him the first approved category III facility in Britain. Site visits have also been requested for a proposed category III laboratory at Imperial College and for the Microbiological Research Establishment at Porton. It is on Porton that British short-term hopes for a category IV facility hang—though for now on some rather delicate strings. Porton is the property of the Ministry of Defence and has been the laboratory in which much of Britain's microbiological warfare research has been carried out. As such it has long been unloved by many academics. Now it is also unloved by the Ministry, which recently announced that it no longer has a use for the microbiological laboratories. Since December their future has been uncertain and is now the subject of a confidential report prepared by the Central Policy Review Staff for the Cabinet (see Britain, page 9). A decision is thought to be imminent.

There are bound to be problems if the decision leaves the laboratories under the control of the Ministry of Defence. If that happened, it is known that a faction of GMAG, led by some of the trade union representatives, would be strongly opposed to the use of Porton's facilities for civil genetic manipulation. That could prevent the go-ahead of any category IV experiments, including the one that has already been given outline approval, until an alternative category IV laboratory could be found. At the moment none are planned but it would not be too far-fetched to suppose that the proposed category III facility currently being completed at the Beatson Institute, Glasgow, could be upgraded if required.

It is Scottish laboratories that have so far taken the lead in applying to GMAG, with their English counterparts being distinctly slow off the mark. Of the expected initial batch of 40–50 applications less than 15 had reached GMAG by its third meeting last month and at least eight of those were from north of the border, mainly from Professor Walker's laboratory.

GMAG has in fact expressed surprise at the paucity of applications and has reminded those concerned that they would be foolish not to present their proposals to the group. At present application to GMAG is voluntary although the UK Health and Safety Commission (HSC) is redrafting its controversial regulations that would make notification compulsory. The original proposals were strongly criticised for being far too wide-ranging, especially as existing health and safety regulations already cover the laboratory hazards of genetic manipulation in the general sense.

The Research Councils have themselves warned of their intention of withdrawing funding of any rogue manipulators. Only industry would therefore be immune from financial sanctions, but the two most interested pharmaceutical companies have already made their intentions clear by submitting proposals to GMAG.

Peter Newmark

It was the first international European body to become involved in guidelines for recombinant DNA research, and has a Standing Advisory Committee on Recombinant DNA chaired by Professor Charles Weissmann. This was set up in January 1976 and held its first meeting in London the following month to discuss whether it was worth elaborating guidelines, other than those available, for Europe as a whole.

At its second meeting, in London last September, the committee compared the NIH and Williams guidelines. It suggested the establishment of national advisory groups to specify containment measures for each experiment on the basis of a detailed protocol submitted to it. The committee specifically recommended against the idea of using some combination of the procedures from the two sets of guidelines. And it advised that experiments forbidden under the NIH guidelines not be carried out.

The European Science Foundation (ESF). Established in November 1974, the ESF is made up of 45 national research councils and academies from 18 European countries and aims to create a close-knit community of science and research in Europe. Sweden quickly suggested to the founding committee that it should consider the whole question of genetic manipulation, including its social, legal and ethical aspects. With the EMBO committee able only to provide advice on request, and then only about scientific and technical aspects, the ESF decided in October 1975 to broaden a preparatory working party into an ad hoc committee on Recombinant DNA which could propose through ESF members whether and what action should be taken at European level.

The committee met three times in 1976 under the chairmanship of Professor Povl Riis of Denmark; members included molecular biologists, physicians and lawyers. Their brief was broad, and they concluded that the recommendations and code of practice of the Williams report should be adopted as the guidelines for recombinant DNA research in Europe. They also recommended that national registries of research should be established and that laboratories should be legally obliged to declare their work to it; laboratories would adhere to agreed guidelines voluntarily, however, and supervision and monitoring would be a national responsibility. National variations, it suggested, should be minimised.

The ESF has now created a new committee made up of representatives of the geemags of its members with the aim of proposing guidelines for Europe. This European Committee on Recombinant DNA will meet for the first time in Strasbourg on 15 March. It will note differences in the practices of various countries and consider prescribing measures for the future.

The European Commission. The European Commission, which has a dual role in the EEC of both initiating and implementing Community legislation, finally jumped into the fray in January. Spotting the opportunity provided by a potential need for Community-wide legislation and harmonisation, Directorate General XII (Research, Science and Education), headed by Dr Gunter Schuster, called geemag heads to Brussels on 21 January for "informal consultations". This offended some sensibilities, not least because Dr Schuster was seeing members of the new ESF committee on which he is himself the EEC's representative.

The Commission is apparently contemplating a directive, the device by which it can request member states to modify and harmonise their legislation. In the case of recombinant DNA research this might involve asking the Nine to ensure that they take the same precautions, but not interfering with the operations of individual geemags. At the January meeting there was no stern objection to the idea, provided a directive was not too specific or detailed.

The worry is not chiefly about Commission interference, although its record in science is less adequate that it might be. Most people recognise that it possesses the authority both to hasten the necessary harmonisation and to incorporate research done in the private sector a common framework. The worry for the moment is related more to the style and timing of the Commission's involvement, which could be self-defeating if it breeds resentment among researchers.

The outcome of the January meeting was presented last week at a meeting in Brussels of the Medical Research Committee, a sub-committee of CREST, the Commission's Scientific and Technical Research Committee. According to the office of the director of the biology programme, the meeting reached no firm conclusions and is due to meet again only in June. That may mean that EEC invlovement will remain peripheral for a while yet. If so, the immediate burden of recommending a path for recombinant DNA research in Europe now lies with the ESF. □

USA

From Carter via Ford

Colin Norman reports from Washington on President Carter's proposed budget changes

AFTER three weeks of frantically sifting through the massive set of budget proposals which President Ford left behind, President Carter last week sent Congress a raft of major and minor amendments. Designed to implement some of Carter's more prominent election promises and political priorities, the proposed budget revisions would undo some of the Ford Administration's parsimony toward health, welfare and housing programmes and add about $19,400 million to previous estimates of government spending in the 1978 fiscal year (which begins on 1 October, 1977).

As far as science and technology are concerned, the only areas which figured prominently in campaign rhetoric were energy and military research and development, and consequently they are the only areas greatly affected by Carter's proposed budget revisions. Outside those two fields, Carter has proposed a small addition to Ford's budget for NASA for studies of possible follow-up missions to the Mars Viking Lander project, and a $5 million increase in the budget of National Institutes of Health (NIH) for research on childhood diseases. Otherwise, the relatively large budget increases for basic research, earthquake prediction and agricultural research proposed by President Ford have been left untouched.

The proposed revisions to the budget for energy research and development are another matter. Acting on the advice of James Schlesinger, his energy adviser, Carter has scaled down Ford's budget proposals for three long-term energy programmes—the breeder reactor, development of large solar power plants and thermonuclear fusion—and redirected some of the funds towards efforts likely to produce short-term results. The proposals signal a major shift in priorities and indicate that the new Administration is prepared to play a more aggressive role than its predecessor in pushing new technologies, such as solar heaters and electrically powered automobiles, into the market-place. The budget pro-

Press report

It is now virtually certain that President Carter will name Frank Press, a distinguished geophysicist from the Massachusetts Institute of Technology, as his science adviser and head of the White House Office of Science and Technology Policy (OSTP). Though no official announcement had been made by the end of last week, Press was already at work in the White House, helping to select candidates for other top science posts in the federal government and attending meetings of Carter's senior advisers. Administration sources indicated that a formal announcement was imminent.

The appointment of Press, which was first rumoured a couple of weeks ago, is something of a surprise. Although he is no stranger to the Washington science policy network, he is not generally regarded as part of the inner circle of the scientific establishment. It was, in fact, widely expected that the job would go to Lewis Branscomb, head of research at International Business Machines (IBM), who coordinated a science policy task force for Carter during the campaign. It has been suggested, however, that Branscomb was ruled out because several people with IBM connections had already been appointed to top posts in the Carter Administration, a fact which has attracted some criticism.

Press was recommended to Carter by a number of prominent scientists, particularly Defense Secretary Harold Brown and Jerome Wiesner, President of MIT, and his appointment has generally been greeted with warm approval in the scientific community. An outstanding scientist, he was elected a member of the National Academy of Sciences at the age of 33. He was Professor of Geophysics at Caltech from 1955 to 1965 and Director of the Seismological Laboratory for much of that time. Since 1965 he has been Chairman of the Department of Earth and Planetary Sciences at MIT.

Among his credentials for the science adviser post is his wide experience in the science and politics of test ban negotiations. He has long been interested in the problem of identifying the seismic waves from underground nuclear explosions and discriminating them from signals from earthquakes. He was a United States delegate to the test ban conference in Geneva in 1960–62, which paved the way for the partial Test Ban Treaty in 1963, and he has been a consultant to the Arms Control and Disarmament Association. In 1968 he was a member of the international working party convened by the Stockholm International Peace Research Institute which reopened the question of monitoring underground weapons tests. Since Carter has frequently promised to see a comprehensive test ban agreement with the Soviet Union, Press's experience in such matters is said to have been a strong point in his favour.

Other relevant Washington experience includes a stint on the President's Science Advisory Committee (PSAC) from 1961 to 1964, and membership of the National Science Foundation, from 1970 to 1976. He is also Chairman of the National Academy of Sciences' Committee on Scholarly Communication with the People's Republic of China, and has travelled extensively in China in recent years.

Even though Press's administrative burden has grown heavier every year, he has continued to make major and distinguished contributions to geophysics. His early work was concerned with seismic wave propagation in the earth's crust and upper mantle, and this eventually resulted in a book *Elastic Waves in Layered Media* in collaboration with M. Ewing and W. Jardetzky. The book had a great influence on the emerging science of seismology. In the 1960s his interests turned to lunar seismology and he was a member of the Apollo team that discovered moonquakes. In the same period he was also encouraging early US research in earthquake prediction as Chairman of the Earthquake Prediction Panel of the Office of Science and Technology. In the late 1960s he started to work on the problem of inversion of earth data by Monte Carlo methods, and more recently his research has included study of the excitation of the Chandler Wobble by earthquakes. In 1974 he published, with R. Siever, a major geology/geophysics text *Earth*.

Colin Norman

---

posals, moreover, are only a foretaste of a comprehensive energy policy which Carter has promised to unveil in mid-April.

The budget revisions suggest that the besieged liquid metal fast breeder reactor (LMFBR) programme is in deep trouble. Carter has recommended that nearly $200 million should be taken out of Ford's budget request for the LMFBR effort next year, a reduction which would still leave $656 million in the programme, but which would cut spending to below this year's level. A statement published last week by the Energy Research and Development Administration (ERDA), which is said to have been drafted by Schlesinger, announced that the entire LMFBR programme will be subjected to an intensive review, to "assess the role of LMFBRs in the nation's energy future, the timing and pace of the breeder programmes and the timing of any decision on whether the breeder would be a viable energy option".

The implications are made clear later in the statement:

> The President's energy priorities, as reflected in the revision of ERDA's (fiscal year) 1978 budget request, stress conservation and nearer-term supply technologies. These priorities suggest that past plans for expansion of the LMFBR program may no longer be viable. Furthermore, serious questions have been raised about the LMFBR technology and the structure of the current LMFBR program. The energy potential of this option must be weighed against the safety questions associated with the LMFBR and the dangers of nuclear proliferation from plutonium reprocessing needed by LMFBRs.

In particular, the review will focus on ERDA's plans to build a demonstration fast breeder reactor on the Clinch River in Tennessee, a project which represents the next major step in the LMFBR programme in the United States. Construction of the Clinch River plant was scheduled to begin later this year, but it will now be delayed pending the outcome of the review. Consequently, Carter has suggested that $85 million be cut from Ford's request for that project alone. No date has been set for completing the review, but it is unlikely that a final decision will be ready in time for inclusion in the energy policy which Carter will unveil in April.

As for solar energy research and development, again, long-term efforts are being cut back to allow more funds to be channelled into programmes likely to produce more immediate results. Accordingly, Carter has scaled down Ford's budget proposal for construction of a pilot-scale solar thermal generating plant, and recommended that the savings be used chiefly to underwrite the costs of producing and testing some 1,300 solar heaters.

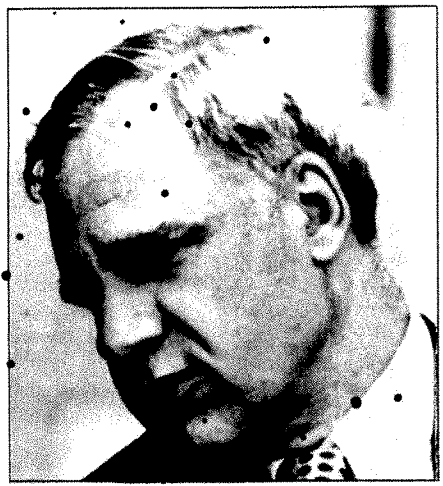
The pilot plant project which Carter wants to cut was only given a go-ahead by the Ford Administration on 7 January. It would entail construction of a 10 MW generating plant in the Mojave Desert in California; the plant would essentially consist of a bank of mirrors concentrating the sun's rays onto a steam generator atop a tower. The project, the costs of which would be shared with electric utilities and government bodies in California, was scheduled for completion in 1980 or 1981. Ford had requested $65 million for the project next year, but Carter has recommended that the budget be reduced to $10 million. The original plan was to follow the California plant with another pilot plant a couple of years later, leading eventually to a commercial-scale plant in the late 1990s. No decision has yet been made on how far the project will be stretched out under Carter's energy policies.

Carter's proposal that more funds be pumped into the production and testing of solar heaters represents a marked change from the policies of the Nixon and Ford Administrations. In 1974, Congress passed a bill to provide federal support for up to 5,000 solar heaters to be installed in public and private buildings and tested over a five-year period. The idea was to stimulate the growth of a solar heating industry, but the Ford Administration was opposed to the principle that the federal government should be so directly involved in the market-place, and the legislation consequently was implemented in a relatively half-hearted manner. Carter clearly shares Congress's view that federal support is needed to commercialise new energy technologies.

Similar views show up in Carter's proposals for energy conservation. He has doubled Ford's budget request for research and development on energy-saving systems, recommending that a total of $318 million be spent next year. Much of the proposed increase would be devoted to programmes designed to increase the efficiency with which energy is used in industry, buildings and transport, but $40 million would also be spent on a programme to provide federal subsidies for the production and testing of electrically powered vehicles. Again, that is an effort which Ford had argued should be the responsibility of private industry rather than of the federal government.

As for the fusion programme, Carter has recommended that $60 million be docked from Ford's request for research on magnetic confinement, leaving $311 million in the programme. He also suggested that Ford's request for laser fusion studies be reduced from $142 to $122 million. Again, the pattern is to decrease support for long-term programmes, but to allow nearer-term efforts to proceed. Thus, the Tokamak Fusion Test Reactor (TFTR), a major facility being built at Princeton University, will be allowed to go ahead, but the completion date would slip by about 6 months, to mid-1981. Similarly, a large magnetic mirror machine planned for the Lawrence Livermore Laboratory would suffer a $10 million cut, but it would also be allowed to proceed with only a minor slip in schedule.

As far as the addition to NASA's budget is concerned, the Carter Administration has unexpectedly recommended that $15 million be spent next year on studies of potential missions to Mars as a follow-up to the successful Viking project; Ford had recommended only $5 million for such efforts. Several candidate missions are under consideration, ranging from refurbishing the back-up Viking spacecraft, which was held in reserve in case the original Viking mission failed, and launching it in 1984, to construction of a new spacecraft to return samples of Martian soil to Earth. The more ambitious missions would probably not be launched until 1988. In any case, planetary scientists are encouraged by Carter's modest budget addition, seeing it as an expression of Presidential interest in the space programme.



Keystone

Energy man: James Schlesinger

The only other budgetary change of note is the fact that Carter has added only $5 million to the budget of the National Institutes of Health. Ford's budget request for NIH was relatively parsimonious, providing an increase of only $40 million, which is insufficient to keep pace with inflation. Congress traditionally adds substantial increases for NIH, however, and the Carter Administration will probably not object if Congress carries on the tradition this year. □

SEVESO

Dioxin damage

Alastair Hay reports on recent developments in Séveso and a possible link connecting dioxin with birth defects.

Official confirmation has now come that at least two of the women who were exposed to tetrachlorodibenzo-*p*-dioxin (dioxin) at Séveso last year have given birth to children with malformations. But the director of health for the Lombardy region, Dr Vittoria Rivolta, is quoted as saying that it is "not yet possible to link the deformations with dioxin contamination". The dioxin was present in the discharge from a trichlorophenol reactor which overheated at the ICMESA chemical plant on July 10.

The first abnormality to be observed was a slight intestinal obstruction in an infant born on 10 January. The mother had apparently eaten garden produce which was heavily contaminated with dioxin. The second case—a "small genital deformation"—was reported on 7 February. But the mother was resident in an area not officially considered to be contaminated by the chemical.

According to Dr Rivolta both infants underwent successful surgery shortly after birth. He added that, in view of the known teratogenic properties of dioxin, the Lombardy regional health department was keeping "a record of all children who are born with deformations from mothers who were in the Séveso area at the time of the explosion".

The developing human embryo is particularly susceptible to teratogenic agents during the period of organogenesis when tissue and organ differentiation occur. In Man this period generally occurs between gestation days 18–55. The children born on 10 January and 7 February would therefore have been at a stage of foetal development beyond organogenesis. For that reason they might be considered to have been less susceptible to the teratogenic properties of dioxin. However, as one mammalian development scientist put it, "We don't know the teratogenic mechanism of dioxin and we have no idea at which stage of its development a foetus ceases to be at risk to this chemical".

School children in Séveso and its

neighbourhood are among the latest victims of chloracne, the skin complaint which can appear as a result of contact with dioxin. The number of children affected is reported to be about 340. Most of them, it seems, have come into contact with dioxin through contamination of school buildings. Indeed, dioxin contamination of the buildings is considered to be too serious to allow the schools to remain open. Following protests from school teachers and parents the Lombardy authorities have closed six schools in the Séveso municipality; they will remain closed until the work of dioxin decontamination is completed.

The decontamination programme itself has come in for much criticism in Italy. Local residents are reported to be incensed over the delay in cleaning the Séveso area and the Italian Parliament is concerned enough to consider appointing a commission to investigate the cause of the delay.

The Lombardy administration's decontamination programme was, in fact, finally approved by parliament only three weeks ago. The proposed plan of action includes the incineration of vegetation, dead animals and polluted topsoil, which is to be removed to a depth of 25–35 cm. This operation should be completed by August, when all the topsoil will have been placed under canvas on a concrete base at a location near the ICMESA plant. The total material to be disposed of is estimated to amount to about 70,000 tons. It will take three years to burn, in a high temperature incinerator which will itself take a year to construct. The whole decontamination programme will, it is estimated, cost £13.5–15 million and will eventually be paid for by Givaudan, the Swiss company which owns the ICMESA plant.

The variability of dioxin contamination has proved a major obstacle for the local authority in formulating its decontamination programme. With some areas considerably more contaminated than others, a detailed relief map of the area has been necessary and this has taken time to produce.

Many residents of Séveso are angry that it has taken so long to devise a graded decontamination programme, with the result that the Lombardy regional government now stands accused of gross mismanagement in its handling of the whole affair. But the outbreak of chloracne among Séveso schoolchildren has resulted in the far more serious charge being levelled that the local authority has minimised the dangers of contamination.

These accusations will now be subjects for consideration by the Parliamentary Commission. For the pregnant women of Séveso, however, no inquiry will relieve their anxiety. If a link is established between the recent infants born deformed and dioxin, the hundred-odd women who were in the first trimester of pregnancy on 10 July and who will reach full term during the next two months face a bleak future. ☐

POLAND

Problem solver

Vera Rich reports on science policy in Poland following the visit to Britain of the Polish Science Minister.

THE recent visit to Britain of the Polish Minister of Science, Higher Education and Technology, Professor Sylwester Kaliski, was essentially a matter of diplomatic routine. No major changes were expected in the existing programme of Polish–British scientific and technical cooperation and educational exchanges, and the immediate practical outcome amounted to little more than the agreement by both parties that such cooperation is of mutual benefit, should be continued and, where possible, expanded. Nevertheless, the Ministerial visit served to highlight and provide an opportunity for discussing several interesting aspects of current Polish policy.

Professor Kaliski told *Nature* that, in addition to 65 "key" problems, Polish science policy incorporates seven "government problems" to be tackled at top-priority level: water resources, coal mining technology, electronics and integrated circuits, copper, building engineering, cancer, and proteins. Two others, energy (including atomic power engineering) and computerisation, are in preparation. In all these fields there are either already technological exchange agreements between Britain and Poland or else approaches have been made by the Poles for such agreements (in certain cases, notably integrated circuits and computers, response is limited by the Co-Com embargoes). Most of these problems lie largely in the field of technology; two, however, cancer and proteins, seem to fall within the sphere of research rather than application.

The inclusion of cancer in such a list of problems is notable. Whereas problems like mining technology or computerisation of production seem amenable to state planning with its targets and schedules, there are no hints of a major Polish breakthrough in cancer research that would make any comparable set of targets more than a list of desideration. Indeed, Poland does not seem to have been assigned a special role in the new Comecon oncological project, which hardly suggests a Polish lead in the field. The explanation may be one of national tradition: Mme Sklodowska-Curie, the discoverer of radium, was a Pole, and the very word radium, to Polish ears, is connected with two roots meaning respectively 'joy' and 'good counsel', attributes associated in the popular imagination with the early hopes of radium as a specific weapon against cancer.

In the field of protein resources, current plans envisage an increase in output of one million tonnes per year by 1980. New sources are being sought, including the production of animal feed from petroleum waste and a programme for eaxploiting the krill resources of the Antarctic. A research ship, the *Professor Siedlecki*, of the Gdynia Maritime Fishing Institute, is at present in the Antarctic carrying out a "scientific reconnaisance" of krill. Last year, the *Professor Siedlecki* brought home krill specimens for investigation by sixteen research institutes in Poland for possible use for human consumption or animal feed.

This year's expedition is testing methods of processing krill. The prospect of krill harvesting on a commercial scale has been causing concern among ecologists in many countries, since krill stands at the head of so many food-chains. Questioned about this, Kaliski stated that at present the krill project was only at the investigation stage and "we cannot tell what its future will be". No ecological problems would arise, he said, for at least ten years. Ultimately, however, there would have to be some kind of international agreement governing the harvesting of krill.

In the current Five-Year Plan, said the Minister, government spending on sciences will be increased by some 70% from 115 thousand million to 200 thousand million zloty. This, he suggested, presumably referring to the involvement of scientists in the current unrest in Poland, is "proof that we don't believe there is a crisis in our country". The financial target is not represented by the budgets to date, which for 1976 and 1977 envisage expenditure on science of 16.6 thousand million and 15.9 thousand million. A considerable increase is to be expected in the last three years of the plan, if the 200 thousand million target is to be reached.

The Minister said that of the total expenditure on science some 12–15% is alloted to fundamental research, and the rest to applied research projects, the latter being financed half from the central budget and half from industry by means of research contracts. The implementation of such applied research in production is Poland's biggest problem. This statement is true also of the Soviet Union, but whereas Soviet scientists frequently receive official rebuke for not producing the results that industry needs, the problem in Poland, says Kaliski, is that they "often have very good scientific results but no chance of introducing them". Poland's scientists, he explained, "think that if they have obtained a result, that it must be introduced". This was not always feasible under a socialist system; under capitalism it would always be possible to find some manufacturer who would undertake to introduce a new process simply for profit motives, but in a system of state planning this was not always possible. To test promising innovations at the pilot stage, he pointed out, the Polish Academy of Science possesses a small pilot factory. The main activity of the Academy, however, is fundamental research and "quality potential", rather than the development of individual applications.

Concerning Comecon, Kaliski said that Poland participated principally in mining, computers, electronics and laser physics. In atomic power engineering, the Poles were "not the leading group—but we all contribute". In the Interkosmos space programme, Poland was concerned mainly with on-board computers, the application of space research to cartography and meteorology, the study of plasma *in vacuo*, magnetic field research, and signal propagation. She was involved in "serious collaboration" in space medicine. Kaliski appeared quite satisfied with the present scheme of financing Comecon research projects by direct contracts between the countries concerned, and showed no interest in the more sophisticated arrangements suggested recently in the Polish journal of international affairs *Sprawy Miedzynarodowe*.

One interesting feature of Kaliski's visit was his meetings with laser physicists. These were not, strictly speaking, in his capacity as Minister. In addition to his governmental duties, Professor Kaliski is head of the Institute of Plasma Physics and Laser Microsynthesis in Warsaw. In an informal lecture which he gave at the Rutherford Laboratory, Chilton, he described the work of the Institute on microthermonuclear synthesis.

BRITAIN

More of the same

The UK Government has published details of its proposed expenditure plans for the next few years and its Defence Estimates for 1977. Chris Sherwell reports

LAST week's White Paper, *The Government's Expenditure Plans, Volume II* (Cmnd. 6271–II, HMSO, £2.35), which follows publication earlier of a general account of the plans, contains the details of individual expenditure programmes. Twelve months ago the government published its plans for the rest of the decade, and these promised a painful levelling off in the growth of expenditure. Since then the government has announced two rounds of further measures, in July and December; the impact of the latter has yet to be assessed and incorporated into figures for 1979–80 onwards.

Unsurprisingly, the latest plans confirm the trend foreshadowed last year. Because organised research and development in Britain has a large government element, this means that the circumstances under which the country pursues its science effort remain far from happy. Some of the details from the White Paper are contained in Table 1 (see over).

For the Ministry of Defence, which is the government's biggest spender on R&D, the table shows only the trend in the overall budget. Latest plans are available in more detail in the *Statement on the Defence Estimates 1977* (Cmnd. 6375, HMSO, £1.50). Expected expenditure on the defence research programme in 1977–78 amounts to £123 million, two-thirds of it devoted to "evaluation and exploratory development" on equipment and weapons, the rest devoted to maintaining a base of scientific knowledge and advancing technology. Another £23 million-worth is linked with civil research.

Defence research did not escape the public expenditure axe last year, and the White Paper confirms this trend too. Implementation of the rationalisation of R&D establishments is described as "well advanced with the first major moves now taking place". By the early 1980s four "systems establishments"—sea, land, air and underwater—complemented and supported by eight "technology establishments", will have replaced the 25 original R&D establishments.

With the reviews of future levels of R&D at Porton complete, work on chemical warfare at the Chemical Defence Establishment (CDE) "can be reduced to about two-thirds its present size", the White Paper says; and the future of the Microbiological Research Establishment (MRE), because microbiological research requirements can be met "by a small team of ten scientists" integrated within the CDE, depends "on the scale and range of civil requirements".

Other details from the White Paper on expenditure include:

- Support for the National Physical Laboratory, the National Engineering Laboratory and Warren Spring Laboratory (the Department of Industry's Industrial Research Establishments), together with department-sponsored work at the Atomic Energy Authority (UKAEA) and the Natural Environment Research Council (NERC), is expected to remain at broadly the same level up to 1980–81. The general industrial research and development programme overall, however, has been reduced by £2 million compared to last year "as a contribution to savings in public expenditure".
- The pattern of funding for R&D in certain aviation fields will be modified if and when the new nationalised industry, British Aerospace, comes into existence with the passage of the Aircraft and Shipbuilding Industries Bill through parliament.
- Reflecting developments in the past year involving the country's nuclear reactor programme, the White Paper says that the provision for R&D by the UKAEA is now "subject to adjustment in the light of the current review" of the programme.
- The Science Budget, which indicates the organised government effort on the civil side in basic sciences, reflects the reductions of last year. Resources devoted by the Science Research Council to 'big science', the White Paper says, will be reduced by about 25% over the survey period. The breakdown for 1976–77 is shown in Table 2.
- In most nationalised industries, but especially electricity and telecommunications, the lower forecasts of investment in fixed assets are the product of revised estimates of demand. ☐

Table 1 Trends in science-related expenditure of UK government (£ million at 1976 survey prices)

	1973-74	1974-75	1975-76	1976-77	1977-78	1978-79	1979-80[1]	1980-81[1]

BANGLADESH

● India's construction of a barrage across the Ganges river at Farakka, about 18 km upstream from the Bangladesh border, is diverting water from the Ganges into the Bhagirathy-Hooghly river. The aim is to flush the silt off the river bed and so keep the Calcutta Port navigable throughout the year. But the project poses a threat for Bangladesh, a densely populated state on a delta whose main artery is the Ganges.

It is estimated that the water from the Ganges and its tributaries serves about 37% of the area of Bangladesh in which about 25 million or nearly one-third of the total population live. About 40,000 cusecs of the Ganges water are redirected into the Hooghly river in dry months, and the effects of such diversion could be severe. Irrigation of 400,000 acres of land dependent on Ganges water was noticeably affected in the last dry season.

According to recent statistics published by Bangladesh Water Development Board, the average discharge of the Ganges at Hardinge Bridge during the last 10 days of December 1976 stood at 74,000 cusecs, as against 47,200 cusecs during the corresponding period of 1975. Before construction of the barrage the flow in this period varied from 118,000 cusecs to 167,000 cusecs; the average flow during March is normally 74,000 cusecs.

Particularly worrying are the rise in the salinity of the water and the extent of saline intrusion into the land from sea. The index of salinity in the Bhairab river went up to 13,600 micromhos per cm^2 in April last year, compared to the historical average of 500 micromhos. The saline penetration inland advanced from the normal 270 km to about 440 km from coast, affecting an area of 6,820 km^2 beyond the limits of past years. The salinity of the Ganges water has since recorded a further rise. In some parts, particularly in Bhairab river, the salinity index has exceeded 15,000 micromhos per cm^2; it may rise further next spring.

The reduced water flow and increased salinity will in addition have deleterious effects on the forest resources of Bangladesh: Sunderbans, the largest forest reserve near the coastal belt, faces the possibility of thinning out and an ecological imbalance for men and animals there. The ecology of aquatic life is also adversely affected: the depletion of water levels in dry months and enhanced salinity have affected the fish population at the key landing sites, and there could be long term effects on spawning cycles, fish size and variety.

● Bangladesh has been elected a member to the 58-member Governing Council of the United Nations Environment Programme (UNEP). The council is one of the semi-autonomous special bodies of the United Nations with headquarters at Nairobi. Asian states have 13 seats in the body; other countries from the Asian Group elected together with Bangladesh are China, Philippines, Indonesia and Syria.

M. Kabir

IN BRIEF

Spacemen return

The latest crew of the Soviet Salyut 5 space station have returned safely after an 18-day flight. The programme of the mission was the now-familiar mixture of astrophysical and geophysical observations "in the interests of the national economy", the testing of on-board instruments and systems, and medical observations. The results of one of the medical experiments, which investigated the threshold sensitivity of the vestibular apparatus to electrical stimuli under conditions of weightlessness, will be used to compile criteria for the selection of future cosmonauts.

Japan has meanwhile launched her first geostationary satellite, on 23 February from the Tanegashima Island Space Centre. Although it is Japan's tenth satellite, it is the first to remain in a geostationary orbit and should bring advances in communications and resources surveying.

Change in Grenoble

Dr John White took over as director of the Institut Laüe-Langevin in Grenoble this week following the departure of Professor Rudolf Mossbauer for a teaching chair at the University of Munich. White's place as assistant director at the Anglo-French-German high flux reactor is taken by Tasso Springer, from the Centre for Nuclear Studies in Julich, West Germany.

EEC geothermal programme

The European Commission is asking for proposals for research and development for the second stage of its geothermal energy programme. The programme, first announced in August 1975, embraces the acquisition of new geothermal data, prospecting methods, and energy from hot water sources, steam sources and hot dry rocks.

Five UK proposals were accepted for the first stage of the programme, including one from the CEGB and two from the Natural Environment Research Council. The EEC will provide about half the cost of the projects involved.

UK reactor choice

Sir Alan Cottrell, the UK government's former chief scientific adviser whose questions about the reliability of the steel pressure vessel of the pressurised light water reactor (PWR) prompted a massive study, has again made public his views about the choice of reactor question. In a letter to the *Financial Times* last week he wrote that Britain "would have little to gain and a lot to lose" by choosing the PWR; he also remained doubtful whether it was right to have to rely for safety on human standards in construction, supervision and operation. He described the merits of SGHWR/Candu and AGR systems as "fairly evenly balanced".

Man management

KENNETH MELLANBY

THE most successful and long-running serial put out on the radio by the British Broadcasting Corporation is *The Archers*, a programme dealing with a farming community in the imaginary village of Ambridge in the midlands of England. Topics of current interest are often introduced: thus Phil Archer, a vigorous and progressive farmer, decides to go on a management course organised by the official Agricultural Training Board. His wife is only being mildly ironical when she says that this will teach him to "avoid friction and frustration with the men, teach a logical approach to human problems, improve their job performance, create team spirit and good morale, and develop effective face to face communication". The even more successful farmer to whom this was said replies: "It won't leave much time for farming". This episode may appeal to the many scientists who are being pressurised to attend similar courses, organised by the training branches of government departments and research councils. They don't leave much time for research.

Most people would agree that many branches of science are developing so rapidly that it would be easy to get out of date, and that some kinds of 'refresher courses' may be useful. However, good scientists usually manage to keep abreast of their subject, and even find little difficulty in dealing with the massive literature reporting new work. It has always been the practice in the better institutions for staff to be encouraged to visit other laboratories where advances are being made, and to attend special courses to learn new methods and techniques.

Instruction in such scientific advances is seldom the concern of the training branches which are now becoming so widespread. They are mainly involved in promoting the teaching of 'management'. In this, they have been encouraged by reforms in the scientific civil service following the Fulton Report; changes intended to improve efficiency and promotion prospects. Trades unions have also pressed for this type of course, believing that it may enhance their members' prospects, even if there are doubts as to whether those attending obtain any real benefit.

I have had the opportunity of trying to assess the effects of these management courses on a good many of my colleagues—men and women employed primarily to do research. I have been unable to detect any improvement in their originality or their productivity, or even in their ability to handle their juniors (or their seniors). The courses seem totally useless in promoting scientific research, they waste time which should be spent in the laboratory and they use scarce funds needed for the research itself. I have found this view shared by the directors of many other establishments.

However, the hope is often expressed that, at a suitable stage in their careers (perhaps when their originality is flagging) more scientists will move to senior administrative posts, and that those who have studied management will then be at an advantage. Has anyone ever carried out a controlled experiment, comparing the performance of the 'trained' and the 'untrained'? I have seen no improvement in those who remain in research. Do these management courses really promote effectiveness in scientific administration—or, for that matter, in business or industry? Until these questions can be answered, we should surely be cautious in encouraging these developments. We should certainly not spend money intended for research, except perhaps to do the research needed to evaluate the courses themselves.

news and views

Some singular proposals

from P. C. W. Davies

ONE of the more intriguing aspects of the theory of relativity is the prediction that the theory itself will inevitably break down in certain plausible situations. When this happens, spacetime is said to develop a singularity. Usually, singularities are associated with intense gravitational fields which grow without limit, such as may occur after the catastrophic implosion of a star to form a black hole. Physicists have always been disturbed about singularities, because if they are taken literally, they imply that there can be regions of the Universe where spacetime develops an edge or boundary, at which all of known physics breaks down. Many have recoiled at this possibility, and view the singularity, less catastrophically, merely as an indication that classical relativity ceases to apply under some very extreme conditions. In the alternative tradition singularities are regarded as actual physical entities of some sort, presumably with their own laws and properties. The issue is of literally cosmic importance because it is widely supposed that a singularity lay at the initiation of the big bang primaeval phase of the Universe. If this singularity is real, it represents a past temporal extremity of the Universe, which, in somewhat anachronistic terminology, means that there was once a creation. If, on the other hand, the singularity is really just a jargon word for a new region of the physical world about which we are presently ignorant, then the Universe will be infinitely old, with all that implies for thermodynamic paradoxes and time asymmetry.

Often the distinction between these alternative viewpoints is blurred. However, Stephen Hawking of Cambridge University, who is never one to be faint-hearted in facing tough questions squarely, has made some challenging proposals about the nature of singularities, particularly with regard to black holes. In a thought-provoking paper entitled 'Breakdown of predictability in gravitational collapse', (*Phys. Rev. D.* **14**, 2460; 1977) Hawking argues for the inevitability of singularities and proposes to make a virtue of them by introducing a new physical principle to stand alongside the Heisenberg uncertainty principle. He claims that the breakdown of physics at singularities does not merely signal our ignorance of the correct theory but represents "a fundamental limitation to our ability to predict the future" a limitation which is in addition to the usual quantum uncertainty. This he calls the principle of ignorance.

Hawking discusses in detail a number of situations in which the principle of ignorance can be applied. In all cases there is an intimate connection between singularities and so-called 'hidden surfaces'. General relativity permits the causal structure of spacetime to develop features such as event horizons, beyond which no information is available. In the case of the gravitational collapse of a star the formation of an event horizon leads to the famous thermal evaporation process discovered by Hawking in 1974, and which endows the black hole with a temperature and entropy. The black hole entropy can best be understood as the loss of information behind this horizon. The main part of the paper is concerned with a detailed mathematical treatment of the evaporation process, and confirms the independent work of Parker and Wald that this radiation is truly thermal in the sense that the event horizon appears to emit with equal probability all configurations of particles consistent with the observers' limited knowledge about the black hole (its mass, charge and angular momentum). The precise connection between the horizon and the singularity is a subtle one, and Hawking's argument seems to depend upon an interpretation of the evaporation process in terms of Feynman's idea of antiparticles being particles travelling backwards in time. The evaporation process entails the creation of particle–antiparticle pairs outside the horizon with one particle falling into the black hole (and thence into the singularity) and the other perhaps escaping to infinity to contribute to the evaporation radiation. Hawking regards this situation as a single particle emanating from the singularity backwards in time, tunnelling to the region outside the black hole, where it scatters off the gravitational field into the future direction, and thereby arrives at infinity. In this way the accepted randomness of the evaporation radiation can be regarded as reflecting a property of the singularity, and is hence a direct consequence of the principle of ignorance. One feature which makes me uneasy about this picture is its dependence on an intuitive, semi-classical idea of particles close to, and inside the black hole, even though the quantum wavelength of the particles is comparable to the size of the black hole itself.

Another situation considered by Hawking, which does not involve an event horizon, concerns the big bang creation of the Universe. Here the hidden surface means any surface sufficiently close to the initial singularity about which we have no previous knowledge. The particles emerging from the singularity will then, according to the principle of ignorance, be random and uncorrelated. This idea is not of course new and has frequently been invoked to account for the observed time asymmetry of the Universe (such as the absence of advanced radiation coming from the big bang). Hawking argues that the characteristics of the cosmic thermal microwave background be explained this way. For example, the high isotropy is beautifully accounted for by noting that an anisotropy can be regarded as the presence of a very large excess of long wavelength gravitons in some modes, which, according to the principle of ignorance, is overwhelmingly improbable.

At a technical level, Hawking points out that the loss of information behind the event horizon of a black hole prevents us from using a pure state to describe the quantum system. The conventional procedure of introducing an S matrix therefore fails when black holes are present. Instead one has to deal with density matrices. This modification could be profound in quite general circumstances if quantum gravity effects are taken into account, because virtual black holes might form out of high energy virtual photons when the wavelength approaches the Planck length.

With such a concentration of provocative new ideas, this paper is bound to generate a great deal of debate about fundamental physics. In particular, Hawking's argument for the inevitability of singularities will be challenged by those who have long sought to avoid them. They could be avoided if quantum matter effects can lead to the violation of the so-called energy conditions. Indeed, negative energies and pressures have long been known to be possible in quantum field theory.

The conclusion which Hawking draws is stated with characteristic wit and daring. There is a new level of uncertainty or randomness in physics because "God not only plays dice, He sometimes throws the dice where they cannot be seen". ☐

Genetic modification of plant cells: a reappraisal

from Edward C. Cocking

CELL genetics is now one of the most rapidly developing areas of plant biology, stimulated by the considerable improvement over the past decade in our knowledge of plant tissue and cell culture, and in particular the availability of isolated plant protoplasts. Genetic modification as a result of the fusion of isolated protoplasts and the regeneration of somatic hybrid plants has advanced dramatically in the past five years.

One of the more controversial aspects of recent developments in genetic modification has been the question of the modification of plant cells by exogenous DNA (see for example Ledoux *Nature* **249,** 17; 1974). The general view now is that the present genetic evidence for the modification of plant cells by prokaryotic DNA is circumstantial and weak. Kleinhofs *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **72,** 27481; 1975) concluded that contamination of plant material by bacteria was the likely explanation for what had been interpreted as evidence for the integration of exogenous DNA, as related to the appearance of "hybrid" bands on centrifugation, since no "hybrid" bands ever turned up provided a stringent sterilisation procedure was used. A re-examination last year by Redei *et al.* (*Proc. Int. Course on Cell Genetics in Higher Plants* (eds Dudits, D. *et al.*) Académiai Kiadó Budapest, 1976) of the correction of genetically thiamineless *Arabidopsis* mutants by bacterial DNA is of particular interest. Using supposed DNA-corrected mutants, supplied by L. Ledoux and others, these workers concluded that the 'corrected mutants' were mechanical contaminants either of Langridge's mutant 1018–6, or other mutants, or were wild type. No evidence of DNA-mediated correction in the material examined could be found. So it must now be recognised that even though the work from Ledoux's laboratory has been a great stimulus, on present evidence there are explanations other than genetic modification for the results obtained.

Somewhat similar conclusions can be reached regarding the work of Hess and collaborators. They observed that treatment of a white-flowering pure line of petunia with the DNA of a red-flowering anthocyanin-synthesising pure line results in a genetically stable correction for anthocyanin synthesis in 0.06% of the treated plants. Bianchi and Walet-Foederer (*Acta botan. neerl.* **24,** 1; 1974) have cogently argued that Hess

Serum thymic factor

from A. J. S. Davies

THE function of the thymus as one of the controlling organs in the ontogeny of immunological responsiveness was defined in the early 1960s. The argument about the manner in which this function is exercised has sputtered ever since. The protagonists of the view that cell outflow from the thymus is largely responsible engendered the concept of the 'T' lymphocyte of thymic origin which is part of our contemporary mythology. The alternative notion, that the thymus functions as an endocrine organ, has led a more chequered life. Its latest form is that the thymus does exert a humoral influence but on lymphocyte populations inside the thymus and perhaps on T cells outside the organ. As J.-F. Bach *et al.* indicate in this issue of *Nature* (page 55) the idea is attractive but the evidence has so far not been compelling.

Bach and his colleagues have concentrated on the isolation and characterisation of a thymus-dependent entity in the serum of pigs. Their material, which they designate *facteur thymique serique* (FTS), they find to be a nonapeptide of determined sequence which they have now synthesised.

The test system used during the isolation procedure of Bach and his colleagues relied upon the capacity of FTS to influence spleen cells from thymusless mice in the sensitivity of their rosette-forming capacity to inactivation by either azathioprine or anti-theta antiserum. This assay is, as Bach himself says, esoteric and it may or may not reflect the manner in which the same material influences cells *in vitro*. In other studies it has been found that partially purified FTS can induce theta positivity, that it can alter the cytotoxic potential of T cells from thymusless mice, that it can sometimes enhance mitogenic responses of lymphocytes and that it can influence the immunological reactivity of the autoimmune NZB mice. All this evidence suggests that FTS can affect T cells, perhaps by modification of their cell membrane, but is far from the proof of either the existence or identity of a thymus hormone and Bach correctly refrains from making such a claim.

Bach's approach has been unusual in concentrating on serum as a source of 'thymus hormone'. It will now be possible to determine whether materials similar to FTS can be obtained by squeezing the thymus itself. Also injection of labelled synthetic material will allow its tissue predilections, if any, to emerge. It would be ironic, but not without precedent in the endocrine system, if FTS production was not in the thymus, but only regulated by it.

FTS will doubtless be widely synthesised and may, like transfer factor, be used for a variety of clinical purposes. There are very many factors which either emanate from or are dependent upon the various components of the lymphoid system. Their disentanglement will rest upon the extent to which their characterisation can be achieved. Bach, in presenting a sequence for a small readily-synthesised biologically active peptide, will certainly engender much fluttering in the lymphocyte dovecotes. The effects of this disturbance could be considerable. ☐

did not take the existing differentiation of the shoot apex into account, when he attempted to interpret his experimental results, and that other explanations are possible for the effects observed (for a detailed critical discussion see Hess in *Plant Cell, Tissue and Organ Culture* 506 (eds Reinert, K. J. & Bajaj, Y. P. S.) Springer-Verlag, Berlin-Heidelberg-New York, 1977).

The recent report by Zryd (*Abstract 191, 9th Int. Conference on Plant Growth Substances, 1976* (ed. Pilet, P. E.) that sycamore cell suspensions plated at low cell density at certain stages of the growth cycle are able to utilise lactose as a sole carbon source is now stimulating a reappraisal of other work using transducing phage to introduce selected bacterial genes into plant cells. Using λp*lac5*-treated sycamore cell suspensions Johnson *et al.* (*Nature New biol.* **244,** 105; 1973) concluded that the *lac* genes were expressed, leading to the formation of enzymes which confer the capacity to assimilate lactose. They stated that their untreated sycamore suspension cultures were unable to use lactose as a sole carbon source.

Somewhat similar experiments using tomato callus have been carried out by Doy *et al.* (*Biochemistry of Gene Expression in Higher Organisms* (eds Pollak, J. I. & Wilson Lee, J.) Reidel, New York, 1972). These results were particularly persuasive, as various bacteriophage controls were used. Inoculation with λp*gal*$^+$ enabled callus to grow slowly on 2% galactose medium for up to 15 weeks, whereas untreated cells and the controls (λp*gal*$^-$ with an amber nonsense mutation in the *gal* operon) died within 3 weeks. In the light of Zyrd's results these experiments should be reassessed; larger populations of cells need to be screened to determine whether tomato, and sycamore, can grow on galactose, and lactose, as a sole carbon source in certain cultural conditions.

Such alternative explanations for the phenomena observed, which have nothing to do with genetic modification, should be rigorously explored. Although it has been claimed that in tomato callus treated with Φ80p*lac*$^+$, specifically *E. coli* β-galactosidase is synthesised, no such positive indication was obtained by Johnson *et al.* It is claimed that the biochemical–immunological test of specific protection at 60 °C is regarded as definitive at the molecular level for bacterial β-galactosidase, but this statement also needs critical appraisal, particularly since it is known that plant β-galactosidases are present in sycamore cells (Keegstra & Albersheim *Plant Physiol.* **45,** 675; 1970), and probably also in tomato callus.

A more promising avenue of approach is the possible use of bacterial plasmids rather than transducing phage for the transfer of prokaryotic DNA to plants. The limitations of the present work on genetic modification as a result of DNA uptake are now evident, but there does still exist the possibility of achieving the desired goal. It is now clear that crown-gall disease caused by *Agrobacterium tumefaciens* is the first example of a natural system in which genetic elements of bacterial origin (the Ti plasmids) play a part in the regulation of gene expression in eukaryotic cells (Schell *et al.* in *Molecular Biology of Plants* (ed. Rubenenstein, I.) Academic, New York, 1977). This raises the possibility of using the Ti plasmids for introducing specific bacterial genes into plants.

The most interesting applications would be the integration of the nitrogen-fixing genes (from *Rhizobium* and other bacteria) into crop plants. The *nif* genes of *Klebsiella* have recently been translocated onto the RP4 factor (Dixon *et al. Nature* **260,** 268; 1976). Schell and his colleagues have suggested that this RP4-*nif* factor could be integrated into the Ti plasmid, which could then be assessed for its ability to make plant cells nitrogen fixing. □

Sexual transmission of hepatitis B

from Arie J. Zuckerman

SENSITIVE techniques for detecting hepatitis B markers have over the past few years revolutionised epidemiological concepts of this infection. The estimated 120 million carriers worldwide cannot be accounted for simply by transmission through infected blood and blood products and the question of whether an apparently healthy carrier can frequently transmit the infectious agent by any other means is now of crucial importance.

Hepatitis B surface antigen, a virus marker, has been found repeatedly in human saliva, menstrual and vaginal discharges, seminal fluid and milk. It has also been reported but not confirmed in bile, sweat and tears. So it is not surprising that contact-associated hepatitis B is apparently of major epidemiological significance, and various aspects of the growing evidence for intimate transmission of the virus were discussed at a postgraduate symposium on hepatitis B held as part of the American Association for Study of Liver Disease meeting last November.

Studies on transmission by intimate contact have however produced varied and sometimes conflicting results. In particular studies on possible transmission by sexual contact have produced ambiguous results. Since the surface antigen has been detected in menstrual blood, vaginal secretions and semen, it is possible that the virus could cross mucosal surfaces during intercourse.

The first indications of possible sexual transmission came some 50 years ago when the husbands and wives of known hepatitis B carriers developed acute hepatitis. Recent studies on the sexual transmission of hepatitis have yielded a wealth of good circumstantial evidence, but also conflicting and sometimes ambiguous information. For example, Mosley (*Am. J. med. sci.* **270,** 253; 1975) reported that as many as 18% of the spouses of patients with acute hepatitis B, but none of their other close family, contracted the infection. Heathcote and Sherlock (*Lancet,* **i,** 1468; 1973) also concluded that sexual contact or close domestic contact seemed to be the most likely source of hepatitis B infection in 40% of 67 patients studied. But a similar frequency of hepatitis B surface antigen was found in registered prostitutes in Athens and in control pregnant women of similar age and socioeconomic status; in prostitutes in Germany and mentally retarded patients in institutions, and among prostitutes and nuns in Columbia.

Nevertheless, several studies carried out in London by a team from the Middlesex Hospital seem to substantiate the possibility of sexual transmission of hepatitis B infection. A high prevalence of surface antigen and surface antibody (the latter providing evidence of infection with hepatitis B virus) has been found in patients attending venereal disease clinics. Promiscuity and in particular homosexual promiscuity emerged as factors of special importance. Thus in one of the studies, homosexuals were found to carry the surface antibody seven times more frequently than their male heterosexual counterparts. In another survey antigen was found ten times more frequently in patients attending a venereal disease clinic in London than in volunteer blood donors (bearing in mind, of course, that these groups are not strictly comparable). Again it was noted that the highest incidence of hepatitis B surface antigen was among male homosexuals.

In the most detailed study to date, of over two thousand persons in New York, Szmuness *et al.* (*Annls intern. Med.* **83,** 489; 1975) evaluated two separate aspects of the role of sexual behaviour in the spread of hepatitis B: first, the possibility that this infection can be transmitted by vaginal intercourse and therefore that hepatitis B may be regarded as a venereal disease;

and second, the indirect impact of certain sexual practices on the spread of hepatitis B virus in various population groups. Serological evidence of infection was sought by very sensitive laboratory techniques. A significant excess of hepatitis B infection was found in two promiscuous groups: patients with venereal diseases and their unrelated sexual contacts (15–18%); and male, but not female, homosexuals (37–51%) (volunteers contacted through homosexual organisations). The prevalence of antigen among male homosexuals was 13 times higher than in the controls, and surface antibody was found 4–5 times more frequently than in the controls, 26 to 28 per cent of spouses of asymptomatic antigen carriers were infected; an infection rate 2–3 times greater than that among spouses of the controls.

Serological evidence of infection with hepatitis B virus was found more frequently in individuals who had a higher than average probability of exposure to potentially infective partners or whose sexual behaviour made such exposure more likely. Large numbers of sexual partners, long duration of homosexuality and predominantly rectal intercourse all contributed to a higher frequency of infection. No antigen carriers were detected in the admittedly small lesbian sample, although antibody was found at the same frequency as in heterosexual women in the general population. This low prevalence may be related to the comparative numbers of sexual partners; in the homosexual sample surveyed the mean number of partners during the preceding six months was 1.8 for women compared with 20 for men.

An unexpected finding reported by Szmuness and associates (*op. cit.*) was the high prevalence of hepatitis B in homosexuals whose sexual behaviour included rectal intercourse, and a relatively low prevalence in homosexuals with practices beyond the bounds of the anogenital system. The explanation for this difference may lie in the reported high incidence of recurrent genital and perianal skin and mucosal sores in the former group.

However, it is extraordinarily difficult to prove by such a cross-sectional retrospective study that hepatitis B can be transmitted venereally in addition to the many other potential modes of transmission. Not only is it difficult to collect reliable information on sexual behaviour, but spouses and highly promiscuous groups differ from each other in many respects, posing problems which cannot be overcome by statistical methods. Nevertheless, several studies have now confirmed that in certain groups intimate contact with large numbers of sexual partners and extravaginal intercourse may be responsible for a substantial proportion of clinically apparent or inapparent infection with hepatitis B virus. But it still could not be proven that type B hepatitis can be transmitted by vaginal intercourse. H. O. Conn, in a paper delivered at the American Association for Study of Liver Disease meeting, pointed out that "it must be borne in mind that people who sleep together may do other things as well. They may share eating utensils, razors, toothbrushes, skin abrasions, needles, lovers and bed bugs; and any of these or others could permit the intimate, but non-venereal transmission of viral hepatitis". ☐

Super-rotating atmosphere of Venus

from Garry E. Hunt

THE atmosphere of Venus is huge, composed mainly of carbon dioxide with ubiquitous clouds obscuring the surface which is characterised by temperatures of about 730 K and pressures of nearly 100 atmospheres. Centuries of visual observation provided little more than frustration to the early astronomers with the regular sight of a yellow, featureless cloud deck, which extends to nearly 100 km above the planetary surface, in complete contrast to Earth which averages about 50% cloud cover. But planetary observations in ultraviolet light have provided the most exciting and unexpected result which still remains today as a major unsolved problem in Venusian meteorology. The upper atmosphere in the neighbourhood of the cloud tops super-rotates. Features in this region move in a retrograde manner with a rotational period of only 4 d which is incredibly short when compared with the planet's own solid-body retrograde rotation of 243 d. So Venus possesses the largest ratio between the atmospheric and planetary rotation rates of any body in our Solar System.

Initial evidence of this atmospheric rotation came from the apparent motion of dark features seen in ultraviolet photographs, characterised by Y and ψ shapes centred on the equator (Boyer & Camichel *Annls Astrophys.* **24**, 531; 1961). But is it really a mass motion that is observed? A wave phenomenon propogating around the planet with a phase velocity corresponding to a 4-d period could produce a similar effect. Although Young (*Icarus* **24**, 1; 1975) considered the super-rotation an illusion, a travelling wave-like disturbance driven by the ultraviolet albedo differences, spectroscopic measurements of winds by Traub and Carleton (*J. atmos. Sci.* **32**, 1045; 1975) and the results of the Venera 8 Doppler drift experiment (Marov *et al. J. atmos. Sci.* **30**, 1210; 1973) provide strong evidence that the visible parts of the Venusian atmosphere really are moving rapidly with respect to the planetary surface. The measured wind velocity is large enough to account for most, if not all, of the 100 m s^{-1} apparent equatorial motion seen in the ultraviolet markings

But how persistent are the observed features? According to Boyer and Guerin (*Icarus* **11**, 338; 1966) the Y feature persists for decades at essentially the same longitude in a coordinate system rotating with a period of 4.067 d. On the other hand, Beebe (*Icarus* **17**, 602; 1972) and Scott and Reese (*Icarus* **17**, 589; 1972) thought that owing to the selective nature of the ground-based observations, the features may actually appear at random longitudes and dissipate after 8–16 d. The high resolution images taken during the Mariner 10 flyby are valuable observations in the study of the lifetime of these features, since Dollfus (*J. atmos. Sci.* **32**, 1060; 1975) has shown them to be representative of the more extensive time series of Earth-based measurements. Belton *et al.* (*J. atmos. Sci.* **33**, 1363; 1976) found that the large scale markings (~ 1,000 km) situated between ±45° latitude have lifetimes greater than 4 d and more with an apparent angular motion at the equator. Smaller scale markings (100–500 km) were found to have lifetimes between 1.5 and 4 d. These observations suggested to Belton *et al.* that the Y and polar ring features seen in the images are both visible manifestations of propagating waves.

But we are still faced with the fundamental question—what is the mechanism(s) capable of generating these large zonal winds? The overhead motion of the Sun relative to an observer fixed on the surface is prograde with a speed of about 4 m s^{-1}. Any theory must then account for the retrograde flow of the order of 100 m s^{-1}. Gold and Soter (*Icarus* **14**, 16; 1971) proposed that the upper atmosphere circulation is a result of a solar torque on a thermal semidiurnal tide. Winds of the observed magnitude could be produced in this way only if the momentum transport were molecular. If, however, turbulent eddies provide the main source of viscous friction, then the mechanism is incapable by several orders of magnitude of accounting for the observed winds.

Schubert and Whitehead (*Science* **163**, 71; 1969) suggested that the 4-d circulation is driven by the overhead motion of the Sun relative to the planet's surface. This is known as the "moving flame mechanism". The solar energy is absorbed in the visible cloud tops situated in the upper troposphere and its effects conveyed to higher levels by various transport mechanisms. Because these mechanisms do not act simultaneously the horizontal movement of the source of heat produces a tilt in the vertical pattern of convection. Associated with the tilt are the Reynolds Stresses which, by transporting horizontal momentum upwards or downwards produce and maintain an altitude-dependent streaming motion. This viscous action transfers horizontal momentum vertically at an equal rate in the opposite direction.

General circulation models, such as those which have been applied to the Earth's atmosphere suggest a numerical approach to the study of atmospheric dynamics. Their first application to the problems of the upper atmosphere of Venus was not very successful (see for example Kalnay de Rivas *J. atmos. Sci* **30**, 763; 1973) producing maximum winds of only 8–10 m s^{-1}, which is an order of magnitude less than those observed. Young and Pollack (*Science* (in the press, 1977)) now report a more satisfactory study producing the observed retrograde mean zonal wind of 90–100 m s^{-1} corresponding to a 4-d rotational period. At an altitude of 60 km their model results show meridional velocities of 10–20 m s^{-1} at mid and high latitudes, a 12 K average equator–pole temperature difference and 3 K day–night temperature difference with the night side hotter. These characteristics agree reasonably well with the observations. Young and Pollack suggest that the large zonal winds in the Venusian atmosphere are the result of a non-linear instability, although the rotation of the planet and the motion of the Sun relative to the surface (moving flame principle) play important parts in determining the direction of the mean winds generated from an initially stationary state. Thompson (*J. atmos. Sci.* **27**, 1107; 1970) first indicated the importance of this instability mechanism which results from the perturbation to a steady convective pattern caused by the superimposing of a vertical shear on this original flow. In the Venusian atmosphere, the relatively large shear is the result of the vertical distribution of solar energy, which is mainly deposited above the 40 km altitude.

The latitude dependence of the mean flow produced by the Young and Pollack model corresponds to a constant angular velocity at a given vertical level. This disagrees with the Mariner 10 observations, which show a more complicated picture of an increase in angular velocity from the equator to a latitude of approximately 50° (Murray *et al. Science* **183**, 307; 1974), where the rotational period may be as short as 2 d. Spiral streaks, which may be interpreted as 'jet streams' show in the Mariner 10 images the flow towards the polar vortices where the kinetic energy of the motions is eventually dissipated.

The return flow of atmospheric gas may occur at deeper levels in the atmosphere in order to maintain the planetary angular momentum balance. We do not know the vertical extent of these motions, whether the stratospheric rotation is a separate overturning cell or whether it is linked somehow to a deep stirring of the huge Venusian atmosphere. Sidi (*Icarus* **28**, 359; 1976) found that a long and narrow striplike cloud formation located within the equatorial region and parallel to the equator appeared to move differently from other clouds in the same area. This suggests that inhomogeneities in the upper atmosphere may exist at two altitude levels at least.

Why is meteorology of the upper atmosphere of Venus so different from that of Earth? The super-rotation requires an efficient high altitude thermal forcing, but for the Earth, the largest amount of available radiative energy is that absorbed at the surface. Could other planetary atmospheres exhibit this excess rotation? Leovy (*J. atmos. Sci.* **30**, 1218; 1973) suggests that any atmosphere where heating tends to produce an equatorial thermal bulge, but which cannot develop instabilities because of slow rotation or large damping, must develop an excess rotation in the same sense as the planetary rotation at a high level. The super-rotation of the Earth's thermosphere reported by King-Hele *et al.* (*Planet. Space Sci.* **18**, 1433; 1970) may be another example. □

Muscle diseases at Birmingham

from E. J. Thompson

The Seventh Symposium on current research in muscular dystrophy organised by the Muscular Dystrophy Group of Great Britain was held at the University of Birmingham on 5–7 January 1977. It consisted of papers invited from workers supported directly by grants from the Muscular Dystrophy Group, and was organised by Professor J. N. Walton, Chairman of the Muscular Dystrophy Group of Great Britain and Professor Sir Andrew Huxley, Chairman of the Medical Research Committee.

AT the meeting various aspects of the development of innervation and muscle biochemistry as well as metabolic, immunological and genetic aspects of human muscle diseases were discussed.

One of the basic questions addressed was—how does nerve leave its molecular footprint on muscle? During normal development, muscle is highly and uniformly sensitive to acetylcholine over its entire surface. However, after innervation, sensitivity is decreased everywhere except at the site of nerve contact. With denervation, the muscle reverts to its less differentiated state, yet the original site of nerve contact remains more sensitive than the surrounding membrane. C. R. Slater (Newcastle General Hospital) described an elegant model which allows systematic study of this phenomenon (work done in collaboration with T. Lømo (University of Oslo)). This involves the implant of a second nerve which requires only 3 days contact with the muscle before it leaves the characteristic cluster of acetylcholine receptors in higher density than the contiguous membrane. One can then ask what is the nature of the molecular cement which maintains the peculiar quarternary structure of these receptor proteins?

G. Vrbova (University College London) compared the difference in the chick embryo pattern of innervation between fast and slow muscle (that is, single rather than multiple synapses per fibre) respectively. She noted that fast muscle was less sensitive to acetylcholine generally and has synapses with a larger space constant. It is thus possible that during normal development the nerves which are destined to induce fibres to become fast muscles exert their particular influence by depolarising a larger area along each muscle fibre.

The increasing use of tissue culture to investigate myogenic cell behaviour in defined conditions has necessitated single cell assays for specific gene products. One such probe has been directed against messenger RNA. K. W. Jones (Institute of Animal Genetics, Edinburgh) has isolated mRNA from heavy polysomes which synthesise two heavy chain myosin molecules. By making a labelled copy of complementary DNA, one can then show selective binding to fixed myotubes and to the cytoplasm between fusing myoblasts. There was no binding to fibroblasts in the same culture. Another specific probe is antibody directed against the individual polymorphic forms of myofibrillar proteins. S. V. Perry (University of Birmingham) has shown that antibody to α-tropomyosin as well as that against troponin T will detect individual fibres in a mixed muscle. Further work on β-tropomyosin as well as troponin I should be forthcoming.

In the discussions on human muscle disease J. A. Simpson (Southern General Hospital, Glasgow) reviewed the evidence that myasthenia gravis is an autoimmune disease. Although there have been some difficulties in transferring the complete myasthenic effect into animals, J. Newsom Davis (Institute of Neurology, London) and R. Miledi (University College London) have found that neuromuscular transmission can be blocked *in vitro* by sera from myasthenic patients. However, Newsom Davis also stated that the level of antibody against the acetylcholine receptor may not closely parallel the clinical status of the patients.

There are several good reasons for considering the role of the cell surface in these diseases. P. D. Smith (Charing Cross Hospital, London) reported that patients with polymyositis had circulating lymphocytes with an increased affinity for intact cultured myotubes and a provocative single patient with myasthenia gravis had a five-fold increase in preferential attachment to the muscle. W. J. K. Cumming (Newcastle General Hospital) found that histocompatability group BW14 was increased ($P<0.001$) in a group of patients with polymyositis. R. Yasin (Institute of Neurology, London) showed an abnormal morphology and behaviour (clustered cells) in cultured muscle biopsies from Duchenne patients.

There are certain reservations as to how closely the mouse model of dystrophy parallels the human situation, but there are, nevertheless, several useful parameters which can be further pursued with this system. M. R. West (Newcastle General Hospital) found that dystrophic mouse, (*dy* 1) muscle appeared to reach a lower level of differentiation than normal muscle in a number of different culture conditions.

The pendulum is clearly swinging back from the neurogenic to the myogenic hypothesis of muscular dystrophy. Recent findings now show abnormalities in the dystrophic muscle without exogenous nerve. The most exciting implications derive from abnormalities on the cell surface which could be linked to both intrinsic biochemical abnormalities as well as a general defect in cell–cell signalling. The question remains as to why there should be pseudohypertrophy of the muscle, that is, proliferation of abnormal amounts of interstitial cells. □

Vitamin D at Asilomar

from Alastair Hay

The Third Workshop on Vitamin D was held in the Asilomar Conference Grounds California, from 9–13 January 1977. The Proceedings of the Workshop, which was organised by A. W. Norman, will be published in full by Walter de Gruyter Co., New York.

The exact mechanism of action of vitamin D (D_2 and D_3) still remains unresolved nearly 60 years after Mellanby reported the presence of an anti-rachitic factor in cod-liver oil; considerable progress has, however, been made over the past 10 years.

It is well known that ultraviolet irradiation of 7-dehydrocholesterol in the skin will ultimately produce vitamin D_3 (cholecalciferol), but the *in vivo* mechanism of production is not well understood. M. F. Holick (Massachusetts General Hospital, Boston) has now shown that the initial product isolated from the skin of rats given no treatment other than ultraviolet irradiation is previtamin D_3, thus demonstrating for the first time that *in vivo* the pathway is at least 7-dehydrocholesterol → previtamin D_3 → vitamin D_3.

Until a few years ago there was no reliable assay for the measurement of the dihydroxy metabolites of vitamin D_3 at the physiological level. Now, however, there are two alternatives for the active hormonal form of vitamin D_3, 1,25-dihydroxycholecalciferol ($1,25(OH)_2D_3$), the assays of Brumbaugh *et al.* (*Science* **183,** 1089; 1973) and Eisman *et al.* (*Science* **193,** 1021; 1976). There may eventually be a third possibility. This was proposed by G. Jones (Hospital for Sick Children, Toronto), who demonstrated that using ultraviolet detectors of sufficient sensitivity, high pressure liquid chromatography (HPLC) can be used to routinely assay vitamin D, 25-hydroxyvitamin-D (25(OH)D), and $1,25(OH)_2D$. Since there is no specific assay for vitamin D itself, and competitive protein binding assays only measure the concentration of an individual metabolite, there would seem to be definite advantages to HPLC for these routine estimations.

Levels of the metabolite 24,25-dihydroxycholecalciferol ($24,25(OH)_2D_3$) found in various studies still prove difficult to interpret. In human volunteers with levels of plasma 25(OH)D in the range 6.0–36.0 $\mathrm{ng\,ml^{-1}}$, C. M. Taylor (University of Manchester) reported circulating levels of $24,25(OH)_2D_3$ within the range 0.3–3.6 $\mathrm{ng\,ml^{-1}}$, and the absence of this dihydroxy metabolite in anephric patients. J. G. Haddad (Jewish Hospital of St Louis, Missouri) however, reported circulating $24,25(OH)_2D$ levels 2–3 times those of Taylor's, and in addition, normal levels of the metabolite in sera from anephric patients. Since anephric patients are missing the kidney enzyme vitamin D 24-hydroxylase, Haddad suggests that significant extrarenal 24-hydroxylase was present in his subjects.

Additional evidence for an extrarenal 24-hydroxylase was provided by H. F. DeLuca (University of Wisconsin); his laboratory has observed the conversion of $1,25(OH)_2D_3$ to 1,24R,25-trihydroxycholecalciferol ($1,24R,25(OH)_3D_3$) *in vivo* in nephrectomised rats and chicks. There is still some scepticism concerning the physiological importance of the trihydroxy metabolite but DeLuca reported that it is present in sufficient quantity *in vivo* to be regarded as significant.

The active form $1,25(OH)_2D_3$ is rapidly accumulated in target tissues. In the gut, for example, it regulates the transcription of the calcium binding protein (CaBP) gene. R. H. Wasserman (Cornell University, Ithaca) reported that in chick intestine in steady-state conditions—such as adaptation to egg laying or calcium or phosphate deficiency—his previous data showed good correlation between CaBP concentrations and calcium absorption. More recent data, however, suggest that another 'vitamin D responsive factor' in addition to CaBP is required for vitamin-D stimulated calcium absorption.

Other 'vitamin D responsive factor(s)' have been observed in the brush border membrane of chick intestine. D. E. M. Lawson (Dunn Nutrition Laboratory, Cambridge) has observed at least two membrane proteins which are synthesised more rapidly than CaBP in response to $1,25(OH)_2D_3$. And H. Rasmussen (Yale University School of Medicine, Connecticut) reported changes in the fatty acid composition of the membrane phosphatidylcholine (PC) fraction in membranes isolated from vitamin-D deficient chicks treated with $1,25(OH)_2D_3$ compared with vitamin-D deficient controls. The changes observed in the PC fraction of the treated chicks—associated with an increased ability of the membrane to take up calcium—were an increase in the ω : 6 fatty acids linoleic and arachidonic, and a decrease in at least one of the ω : 3 series, docosahexaenoic acid.

The functions of the two dihydroxy metabolites 24,25(OH)$_2$D$_3$ and 25,26(OH)$_2$D$_3$ are still far from being resolved. J. A. Kanis (Nuffield Orthopaedic Centre, Oxford) suggested that 24,25(OH)$_2$D$_3$ may act directly on bone to increase mineralisation, on the basis of the observation that 1 μg d^{-1} of 24,25(OH)$_2$D$_3$ (R+S epimers) administered to an anephric patient with osteomalacia, increased intestinal calcium absorption and reduced plasma alkaline phosphatase, without causing an increase in plasma or urine calcium. These effects were not observed by A. M. Pierides (University of Newcastle upon Tyne) however, in patients receiving as much as 16 μg d^{-1} of 24,25(OH)$_2$D$_3$.

The most ignored dihydroxy metabolite of vitamin D is certainly 25,26(OH)$_2$D. Very little is known about its properties and its *in vivo* origin is completely unknown. That it is a significant metabolite in man at least, was clearly demonstrated by E. B. Mawer (University of Manchester). In vitamin D replete individuals the serum concentrations of 25,26(OH)$_2$D and 24,25(OH)$_2$D are similar. Whereas the production of 1,25(OH)$_2$D$_3$ and 24,25-(OH)$_2$D$_3$ are governed by parameters such as the state of vitamin D nutrition and serum calcium concentration, no such controls are evident for 25,26-(OH)$_2$D$_3$ synthesis.

The papers referred to were only a few of the highlights of this workshop. But they do indicate that the next decade should be fruitful. By the 1980s the functions and mechanisms of action of all the vitamin D metabolites should be known, and the importance of 1,25(OH)$_2$D in phosphate regulation should be determined. The answers to these questions should provide reliable therapeutic procedures for the treatment of clinical disorders such as the renal osteodystrophies and postmenopausal osteoporosis. ☐

Minicomputers for quantum chemists

from Graham Richards

QUANTUM chemists have always been major users of the most powerful computing facilities. Indeed, in recent years, the advances in the subject have followed the introduction of each new generation of machines and the capability of doing the best work has, to a large extent, been limited to those with access to major computing centres. As a result the subject has been dominated by a small number of groups and not used as a tool by more applied chemists to study or clarify their own research problems. The rapidly falling cost and increasing power of minicomputers should lead to a radical change if it were possible to perform the massive *ab initio* quantum mechanical calculations on minicomputers rather than giant number-crunchers. A pilot study which succeeds in getting the quart into a pint pot and studying genuinely interesting problems has been conducted in the Chemistry Department in Berkeley.

The question "are minicomputers suitable for large scale scientific computation?" was answered in the affirmative by Schaefer in a paper presented at the IEEE Computer Society Conference held in Washington in September 1975 and in the proceedings of that meeting the relative capabilities and suitability of a number of minicomputers are compared. Since that date memory prices have fallen and new developments such as high speed array processors make the use of the minicomputer a very attractive alternative to the use of expensive large machines.

Calculations may take of the order of 30 to 40 times as long on a minicomputer as they do on a large scientific machine. However, since the calculations may be run overnight and the machine can be operated by graduate students or research personnel rather than professional operators, it may be much cheaper to work in this way.

The molecular structure calculations which have been attempted using a minicomputer have not been limited to the study of simple electronic ground states of closed-shell molecules. The Berkeley group has studied the excited electronic states of both glyoxal and ketene (*J. Am. chem. Soc.* **98**, 401, 2689; 1976). For each of the molecules, some 20 excited states are included and details are given of geometries as well as excitation energies.

The same minicomputer provided the means of studying some fundamental chemical reactions with *ab initio* molecular orbital calculations. Two reactions involving methylene have formed the subject of articles in the *Journal of the American Chemical Society* (**98**, 1653, 3073; 1976). For the least-motion insertion reaction of methylene and hydrogen to yield methane the transition state geometry and activation energy were calculated and the abstraction reactions of triplet methylene with hydrogen and methane studied in the same way. For the methane abstraction

$$CH_2(^3B_1)+CH_4 \rightarrow CH_3+CH_3$$

the work implies that the reaction should not occur to a significant degree at room temperature contrary to the predictions of Dewar based on his semi-empirical MINDO calculations.

Although it is still early to be sure that the minicomputer will lead to a welcome change of life for quantum chemists it is striking just how wide is the range of problems tackled to date with the relatively cheap form of computer. Not only have quantum mechanical calculations been performed, but semiclassical computations, such as atomic scattering from solid surfaces, have also been studied in this way; an example being the scattering of helium and neon from tungsten, the work of Miller and his colleagues (*J. chem. Phys.* **64**, 45; 1976).

If quantum chemistry can be made inexpensive enough for chemists in experimental research laboratories to run their own calculations then the day may at last come when experimentalists can run their own calculations routinely. This will save the literature being over-burdened with details of computations which may be directly interesting only to a small audience, and will enable practical chemists, such as medicinal chemists, to reap the benefit of useful calculations without needing to persuade a theoretical group to take on their work. ☐

A hundred years ago

THE total expenditure on the new building at South Kensington for the reception of the Natural History Collections now in the British Museum is stated in the new Civil Service Estimates to have been 206,472*l*. up to September 30 last. A further sum of 36,650*l*. is required to carry on the works up to the end of the present financial year. This amount has been already voted. The proposed vote for the present financial year 1877–78 is 70,000*l*., leaving the amount of 1,878*l*. necessary to complete the building, the total estimate having been 395,000*l*. We may remark that it is not only in this country that a new Museum of Natural History is in progress. Both at Paris and at Berlin the present buildings for the National Museum are found to be too small, and large sums are to be appropriated to their reconstruction.

From *Nature* **15**, March 1, 382; 1877.

review article

The continental drift debate

F. J. Vine*

The controversy within the earth sciences over the hypothesis of continental drift has been unusually protracted. Here Professor Vine reviews the history of the debate as recorded in the pages of Nature.

THE name most commonly and correctly associated with the hypothesis of continental drift is that of the German meteorologist Alfred Wegener (1880–1930). Wegener's first article on the subject appeared in 1912 and the first edition of his book *Die Entstehung der Kontinente und Ozeane* (The Origin of Continents and Oceans) in 1915. Presumably because of the first World War and the lack of an English translation, a review of Wegener's book did not appear in *Nature* until 1922[1] by which time a second edition was available (published in 1920). It seems probable that this together with Wegener's article in *Discovery* in 1922[2], constituted the first widespread exposure of the "Wegener hypothesis" to the English-speaking world and it prompted a great deal of discussion at scientific meetings and correspondence in *Nature*.

It is perhaps instructive to ask why it was that geologists had paid little attention to the concept of continental drift before the publication of Wegener's book, for Wegener was certainly not the first to suggest that the continents were once together and subsequently drifted apart. Several contributors to *Nature* in the 1920s were at pains to point out that Wegener was anticipated by, among others, Oswald Fisher (1882), W. H. Pickering (1907), F. B. Taylor (1910) and H. A. Baker (1911); and A. A. Robb in 1930 (ref. 3) unearthed and reproduced the reconstruction of the continents around the Atlantic published by Antonio Snider in 1858. A particularly concise and authoritative account of the philosophical development of the concept before 1900 appeared in *Nature* in 1970[4]. It was written by N. A. Rupke who identified, I think, the main reason why geologists did not consider drift before the publication of Wegener's ideas. All the earlier advocates had associated drift with a catastrophic event. Even Taylor, who, quite reasonably, suggested that drift might explain the formation of the Atlantic and Indian oceans and the young fold mountain belts, invoked the origin of the Moon out of the Pacific in the mid-Cretaceous as the ultimate cause. Although the earliest geologists were well-versed in biblical catastrophism, the concept of 'uniformitarianism' or 'actualism', first advanced by James Hutton and Sir Charles Lyell in the early nineteenth century, gradually replaced this earlier philosophy so that by the turn of the century the invocation of any sort of catastrophic event to explain geological phenomena was something of an anathema to all right-minded geologists. Surprisingly perhaps, Wegener's hypothesis was the first to formulate the concept of drift within the framework of 'uniformitarianism', that is, by processes operating today which have operated slowly but inexorably throughout time.

In addition Wegener went further than anyone before in attempting to document the geological and geophysical evidence for drift, and to provide, albeit rather unsuccessfully, uniformitarian mechanisms whereby drift might be taking place. Wegener was attacked on all three counts, on the basis of the geological and geodetic evidence he invoked, and the mechanisms he suggested. The debate dragged on inconclusively for 30 yr until even the perspicacious Arthur Holmes was driven to write, in 1953[5] "I should confess that, despite appearances to the contrary, I have never succeeded in freeing myself from a nagging prejudice against continental drift; in my geological bones, so to speak, I feel the hypothesis to be a fantastic one". However, the end was in sight; the advent of new and independent evidence suggestive of drift, from palaeomagnetic studies, resuscitated the idea in the late fifties and early sixties, and subsequently the post-war investment in marine geology and geophysics paid off in the form of providing compelling evidence for sea-floor spreading and hence continental drift. By the late 1960s the vast majority of geologists and geophysicists were convinced that continental drift was a reality; it was as if "the dream of a great poet" (Termier's words in 1926) had come true.

The reviewers of the various editions of Wegener's book which appeared in the 1920s seem to have suffered from a mixture of shock, incredulity and even some initial enthusiasm on reading Wegener's heretical ideas. The reviewer of the second edition[1] refrains from passing judgement, but concludes that "The revolution in thought, if the theory is substantiated, may be expected to resemble the change in astronomical ideas at the time of Copernicus". It is interesting to note that J. Tuzo Wilson made precisely the same analogy 45 years later following the essential confirmation of Wegener's hypothesis[6]. Grenville Cole[7] in a somewhat flowery but careful review of the third edition of Wegener's book could not decide whether to be serious or frivolous in discussing it. On the whole he took it seriously, if only as a challenge, and in so doing made some very interesting points. Gregory's review of the English translation of the third edition by J. G. A. Skerl also makes interesting reading[8]. Gregory is obviously stimulated by the boldness of

---

*School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ, UK.

Wegener's ideas and maintains that they were being favourably received by geologists in general at that time, an impression which is not corroborated, however, on reading other items of this period. Gregory is preoccupied with a possible connection between Asia and North America across the Pacific which he deduces on palaeontological grounds. Although he finds this inconsistent with Wegener's theory he finally admits that "The original theory has undergone so many modifications and its author is so delightfully open-minded, that it may be changed to agree with a trans-Pacific land connexion". Indeed more than forty years later J. Tuzo Wilson made just such an accommodation by suggesting that a fragment of southeast Asia (Cascadia) was rafted across the Pacific and accreted on to the western margin of North America[8].

An early convert to Wegener's ideas, J. W. Evans, writing in 1923[9], made some rather pertinent observations on continental margins, predicted largely submerged microcontinents and emphasised the futility of fitting coastlines rather than shelf edges in making continental reconstructions. Such a geological *faux pas* was committed as recently as 1962 by Sir Harold Jeffreys[10]. In this letter Jeffreys maintained, as he had done previously, "that Wegener's alleged fit of South America into Africa is a misfit by about 15°. This is obvious on inspection of a globe". Cambridge legend has it that it was this assertion which prompted Sir Edward Bullard to make his well-known and much reproduced 'computer fit' of the shelf edges bordering the South Atlantic[11]. Bullard's fit was near perfect; Sir Harold, of course, had been referring to the coastlines. Bullard's fit is in fact virtually identical to that obtained nearly 10 yr earlier by S. W. Carey using an analogue technique[12].

Carey, Professor of Geology at Hobart, Tasmania, is one of a long line of southern hemisphere geologists who championed drift through thick and thin, largely on the basis of the geological record of the southern continents plus India which suggests that they formed a single super-continent—Gondwanaland—for a period of at least 200 Myr before 200 Myr ago. It is not surprising therefore to find that some of the items appearing in *Nature* in the 1920s[13] indicate a favourable reception for Wegener's ideas in South Africa. It is also significant that one of these reports mentions the South African geologist A. L. du Toit. Alexander du Toit became one of the greatest advocates of continental drift, effectively taking up the banner of drift following Wegener's untimely death on the Greenland ice cap in November 1930. Ultimately du Toit published his classic text on drift—*Our Wandering Continents*—in 1937: and it was briefly reviewed for *Nature* by E. B. Bailey in 1939[14].

Of the relevant items which were contributed to *Nature* during the inter-war period, two, I think, are gems: the report of a Princeton summer school, written by E. B. Bailey in 1927[15], and the review of the proceedings of the Symposium on Continental Drift, held in New York in 1926, written by Arthur Holmes in 1928[16]. Bailey's account of the "Princeton Summer School of Geology and Natural Resources" 1927, led and organised by the legendary R. M. Field, makes fascinating reading. He is obviously fresh from, and filled with enthusiasm by, his two traverses of the North American continent. The result is a very vivid account of, and, one suspects, some very profound comments on, North American geology. At one point in describing the geology of Pennsylvania he is so struck by its similarities with the British Isles and Europe that he exclaims "It is as if the Atlantic did not exist or, in other words, as if Wegener, after all were a true prophet".

Holmes's review relates to the proceedings of the famous, if not infamous, mid-year meeting of the American Association of Petroleum Geologists, held in New York during November 1926. The meeting was subtitled "a Symposium on the Origin of Movement of Land Masses, both Inter-Continental and Intra-Continental, as proposed by Alfred Wegener". Wegener himself was present and the North Americans in particular gave him what would be termed in their own parlance "a hard time". In fact it is often said, with relatively little exaggeration, that as a result of this meeting no North American geologist seriously considered the possibility of drift for the next 40 yr. However, this was not true of all European geologists and certainly not of southern hemisphere geologists, as noted above. Holmes himself was one of the European geologists who was not at all averse to drift but was concerned that many of the particular arguments which Wegener used did his cause more harm than good. He noted that "There is, indeed a distinct danger that the easy disproof of large sections of the Wegener hypotheses may be mistaken for a demonstration of the impossibility of continental drift as a geological process. The important issue is now not so much to prove Wegener wrong as to decide whether or not continental drift has occurred, and if so, how and when". With the advantage of hindsight this strikes one as being a very profound summary of the situation pertaining at the time, and indeed for the following forty years. Because of his own prejudice in favour of drift, Holmes had the insight to pick out some of the more constructive and enduring suggestions made at this symposium. Thus he alighted on the suggestion of van der Gracht, "that there may have been a pre-Carboniferous 'Atlantic' which was closed up by the Caledonian diastrophism" a concept which was to be formulated in much greater detail 40 yr later by Wilson[17] and Dewey[18]. Again taking his cue from van der Gracht he states his own preference for convection in the mantle as the driving mechanism for continental drift, this being apparent from his other writings at this time[19]. Both it seems were following the suggestion of Ampferer[20] and others. Holmes goes so far as to conclude that "Geophysics will not be in a position to deny continental drift until it has thoroughly explored the possibilities of convection or other currents in a highly viscous substratum, and the forces set up by the interaction of magnetic and electric fields".

Several correspondents, quite justifiably, doubted the accuracy of the geodetic measurements which, Wegener claimed, substantiated that drift is occurring at the present time[21]. It is interesting to note that only now are relatively new instruments such as the mekometer, and new techniques, such as satellite and lunar ranging, providing the accuracy required to make direct measurements of drift. Even accurate measurement and monitoring of *intra*-continental crustal movements had received scant attention until the institution of the international 'Geodynamics' project in 1970 and the increased interest in earthquake prediction of recent years. Other letters bring out the limitations of fossils as indicators of continental drift and the inconclusive and often conflicting nature of the evidence provided by palaeontology[22].

It is perhaps not surprising therefore to learn that very little was written about the possibility of continental drift between 1930 and 1960, that is, following the initial discussion in the wake of Wegener's book, and before the revival of the debate following the palaeomagnetic discoveries of the late 1950s. It is also noticeable, and probably significant, that the first article on continental drift to appear in *Nature* is dated 1960. Before this all the contributions were reviews, reports, letters, presidential addresses or accounts of special lectures or discussions. Clearly this could be a result of editorial policy but in fact it is true of the geological literature as a whole during this period. It is as though no self-respecting geologist in the Northern Hemisphere was prepared to risk his reputation by publishing a full-length article on continental drift.

We are not, however, left completely without written records during these years; in fact two very useful summaries of the status of the debate were given by Watts in 1935[23] and Good in 1950[24], of which the latter is considerably less objective than the former. Perhaps one of the most pertinent statements made in this period was that of Sir Thomas Holland commenting on du Toit's demonstration of the remarkable similarities between the geology of Africa and South America from Lower Palaeozoic to Upper Mesozoic times: "If it be true that these continental masses have moved horizontally in late geological times away from one another, there is no reason why others should not have done so too, in spite of the circumstance that no completely satisfactory explanation of the mechanics involved can be offered at present. Further work on the lines so ably undertaken by du Toit is now more necessary than mathematical criticism with insufficient quantitative data regarding the physical state of the Earth's sub-crust under the continents and oceans"[25].

Towards the end of the period 1930–1960 it was often said that southern hemisphere geologists found it necessary to invoke drift because of the geological record on their continents but that northern hemisphere geologists found the geological evidence for drift equivocal. Even Holmes seemed to lose some of his initial enthusiasm for drift as is apparent in the review written in 1953 (ref. 5). I always found this very puzzling in that it seemed to me that the evidence for the former continuity and juxtaposition of structures, faunal provinces and even lithologies across the North Atlantic is at least as compelling as that for the reassembly of Gondwanaland. It came as no surprise to me therefore to find that British geologists such as Bailey[15] and Trueman[26] had been saying this as much as 30 yr earlier but that their witness had largely gone unheeded. It was as though most geologists and geophysicists considered drift to be disproved because of the inadequacy of the geodetic data and mechanisms that Wegener appealed to, and the unacceptable historical association with catastrophism which was perpetuated, unfortunately, by certain writers, well into the 20s and 30s. Taylor, for example, in 1926 (ref. 27) modified his ideas by postulating the capture of the Moon in mid-Cretaceous time rather than its origin out of the Pacific but this was still too catastrophic and non-uniformitarian to satisfy the geologists[16].

In spite of the fact that most geologists by the mid-1950s had rejected drift on the basis of geophysical and philosophical arguments, many geologists had from the outset acknowledged that the ultimate test of drift must come from the empirical evidence, that is, the domain of geology[28]. In fact, in the event, it was very empirical data which convinced most Earth scientists of the validity of continental drift, but data which derived from a marriage of geology and geophysics. Fundamental to these new discoveries was the development of the science of palaeomagnetism, the study of the intensity and direction of the Earth's magnetic field in the past as recorded in the permanent magnetism of rocks. If it is assumed that the Earth's magnetic field was essentially dipolar in the past, as it is today, then it is possible to test the hypothesis that the continents have changed their relative positions (except in the unlikely event that all relative movement has been along lines of magnetic latitude). If one makes the additional assumption that the magnetic field has been axially dipolar in the past as it is thought to have been recently, when averaged over thousands or tens of thousands of years, then clearly one can deduce the palaeolatitude of a particular continental area at any given time, and its orientation with respect to the meridian. Essentially, palaeomagnetic results confirm the hypothesis of continental drift as envisaged by Wegener and in particular vindicate the palaeolatitudes he deduced, on palaeoclimatic grounds, for his supercontinent of Pangaea during Permo-Carboniferous times[29]. Detailed palaeogeographies and palaeolatitudes for particular times, however, are still somewhat equivocal because of the limitations of the method. As Sir Edward Bullard is reputed to have said, "There is nothing in this field which could not be solved by palaeomagnetism if the results were ten times more numerous and the method ten times more accurate".

The decade of the 1960s also saw the confirmation of drift in terms of a sudden and spectacular advance in our understanding of the origin and evolution of the ocean basins. The theory which set the stage for this breakthrough first appeared in print in the pages of *Nature* in 1961 (ref. 30). It was presented by R. S. Dietz who termed it "sea-floor spreading", but the idea was originally conceived by H. H. Hess, as Dietz subsequently acknowledged[31]. Hess's original article was circulated as a preprint in 1960 and finally appeared in print in 1962 (ref. 32). Subsequently two important riders were added to the spreading sea floor hypothesis by Vine and Matthews in 1963 (ref. 33) and by Wilson in 1965 (ref. 34). The first proffered an explanation of the pronounced and linear oceanic magnetic anomalies and the second an explanation of the abrupt offset of mid-ocean ridge crests along transverse fracture zones. Both were later substantiated; the Vine and Matthews hypothesis as a result of the definition of a geomagnetic reversal time-scale and the acquisition of more magnetic anomaly data, and the Wilson "transform fault" hypothesis as a result of improved epicentral locations and focal mechanism solutions for earthquakes occurring on the oceanic fracture zones.

It is probably true to say that for most uncommitted geologists and geophysicists the most compelling and decisive evidence in favour of continental drift was provided by the data confirming the Vine–Matthews hypothesis, which were presented by Pitman and Heirtzler[35] and Vine[36] in 1966. The first public presentation of these results occurred at a conference in New York in November 1966, 40 yr to the month after the fateful meeting in New York in 1926. At this meeting also, L. R. Sykes presented the new seismological evidence which provided striking confirmation of Wilson's "transform-fault" hypothesis[37], thus providing additional confirmation of the hypotheses of spreading and drift. Soon after this both hypotheses were reformulated by McKenzie and Parker[38] and Morgan[39] in terms which became known as "plate tectonics". The concept of plate tectonics is itself an outgrowth of Wilson's transform fault hypothesis and the remarkable success of continental fitting at shelf edges which implies long term rigidity of vast areas of the crust and uppermost mantle.

In spite of the fact that the continental drift debate was not settled to most peoples' satisfaction until 1966 or 1967, most articles which appeared in *Nature* from 1960 onwards are favourably disposed towards it. This is not so representative of the geological literature as a whole during this period but probably reflects the fact that most of the initial palaeomagnetic results were obtained in British laboratories and as a result of this many British geophysicists were converted to belief in the theory. In addition, *Nature* seemed to attract many of the classic articles which paved the way for the ultimate proof and acceptance of the theory.

An article by Wilson in 1960 (ref. 40) provided an interesting curtain raiser to this final chapter of the continental drift debate. This article is doubly interesting because before this Wilson was in no sense a convert to drift and yet in this 'transitional' article one can see the beginnings of ideas which eventually amounted to sea-floor spreading and plate tectonics. He does this by allowing a certain amount of expansion of the Earth to account for the mid-ocean ridges. Other authors have favoured much larger scale

R392

expansion on the assumption that the Earth was originally entirely covered by continental crust[41]. This would involve a fivefold increase in volume, either since the Earth was formed or since drift was initiated. Such an idea has also been championed by S. W. Carey and B. C. Heezen. It has roots which go back to the mid-nineteenth century as mentioned by Rupke[4], but has never gained wide acceptance. With the advent and success of plate tectonics it now seems unnecessary and inappropriate to invoke large-scale expansion, although it has recently been revived yet again by H. G. Owen[42,43].

Despite the compelling evidence which has corroborated sea-floor spreading and continental drift within the past decade certain fundamental problems regarding the detailed reconstruction of Gondwanaland have persisted. These are, notably, the position of Madagascar against Africa[44] and whether parts of south-east Asia should be included in Gondwana[45,46]. In time, presumably, both problems will be solved by further palaeomagnetic studies, and indeed this stage may have been reached with respect to Madagascar, recent palaeomagnetic results favouring a southward motion relative to Africa as originally suggested by du Toit[47,48]. The question of the driving mechanism for drift and plate tectonics is also equivocal although some stimulating ideas have been derived in recent years from seismic studies of lateral heterogeneity in the mantle[49,50] and consideration of 'absolute' as opposed to relative plate motions[51,52].

I think it will be apparent from the foregoing that as regards the resolution of the continental drift debate, which was clearly fundamental to so many aspects of the science, geology stood still for essentially 40 yr, mainly it seems because geologists attached greater importance to the physical arguments rather than the geological evidence. It was as though the following remark of Eddington in 1922 fell on deaf ears, for it could equally well have been said in 1962.

"The time has gone by when the physicist prescribed dictatorially what theories the geologist might be permitted to consider". A. S. Eddington in an address to the Geological Society of London, 21st November 1922 (ref. 53).

Shape and pattern specification during microtubule bundle assembly

J. B. Tucker

Department of Zoology, The University, St Andrews, Fife KY16 9TS, UK

The ways in which control of microtubule packing, linkage, and nucleation of tubule assembly, may be related to the cross-sectional shaping of developing microtubule bundles are explored.

In certain types of microtubule bundles the tubules are packed and linked together in precisely defined configurations. Many of these bundles are called axonemes (axle-threads) because they run along the central longitudinal axes of slender cell processes such as cilia, flagella, sperm tails, suctorian tentacles, and the axopodia of certain rhizopods[1]. On the other hand, highly ordered microtubular axostyles and nemadesmata are situated in the cell bodies of certain flagellates and ciliates[2]. Ciliary and flagellar axonemes with the well-known nine-plus-two microtubule configuration occur in a wide range of eukaryotic organisms and cell types. All the other types of highly ordered microtubule bundles so far described have only been found in certain unicellular 'organisms' such as protozoans, phytoflagellates, and the spermatozoa of a few arthropods[1,3,4].

These microtubule bundles are particularly suitable cell components for analysing control of growth and form at both the molecular and ultrastructural levels. The tubules are often packed in simple repeating patterns and the shapes and dimensions of microtubule bundles are sometimes specified with considerable exactness. Microtubule bundles are two or three orders of magnitude larger than viruses but the highly ordered architecture of most tubule bundles seems to result, like that of certain virus coats[5], from the self-assembly of large numbers of protein sub-units although only a small number of protein species are involved. Some of the control processes operating during the morphogenesis of microtubule bundles are likely to be similar to those concerned with the deployment of less compact and well ordered microtubule arrays Such arrays are an important feature of the organisation of most eukaryotic cells and are associated with various fundamental cell activities, including anaphase chromosome movement, hormone secretion, axonal and certain other forms of intracellular transport, formation of plant cell walls, and cell shaping and locomotion[6–10].

Does assembly proceed along basically similar lines for all microtubule bundles? The following account considers control of assembly for several types of bundles and provides some indication of the range of assembly procedures which are likely to operate It also indicates that construction of different types of bundles involves different combinations of assembly procedures For example, prefabrication of non-microtubular structures which act as templates seems to be required for direction of early stages in the assembly of some, but not all, types of microtubule bundles.

Nucleation of tubule assembly

Two closely related[11] (molecular weight about 55,000) protein sub-units, α and β tubulin, self-assemble in certain conditions to form microtubules[12,13] The tubules of a microtubule bundle almost invariably start to assemble in very close proximity to each other in a particular cell region Sometimes the number of tubules which start to assemble is specified exactly[14]. These observations imply that initiation of the assembly of each tubule of a bundle is nucleated *in vivo* by a special non-diffusible 'nucleating element' which is located in a particular cytoplasmic region If this were not the case, the substantial pools of tubulin which are present in some cells before tubule assembly starts[15–19] should almost always polymerise to form variable numbers of randomly oriented tubules, and rarely form tubule bundles with well defined numbers of closely adjacent tubules oriented parallel to each other The molecular nature of nucleating elements is unknown They differ in at least some detail from the ring-shaped tubulin aggregates which nucleate tubule assembly *in vitro*[20–22] because these aggregates can assemble from freely diffusible components. It is possible that the aggregates nucleate assembly of bundle tubules in *in vivo* conditions if they associate with certain non-diffusible components. If this is the case, it is the latter which represent the effective nucleating elements *in vivo*

Cytoplasmic localisation of bundle tubule assembly is achieved because the nucleating elements are usually bound together and may be attached to the surface of some other cell component[23–25] Concentrated groupings of nucleating elements and materials which connect them together have been termed microtubule-organising-centres (MTOCs) (ref. 26), nucleating sites, nucleating centres, and initiating sites[27] We have adopted the term MTOC.

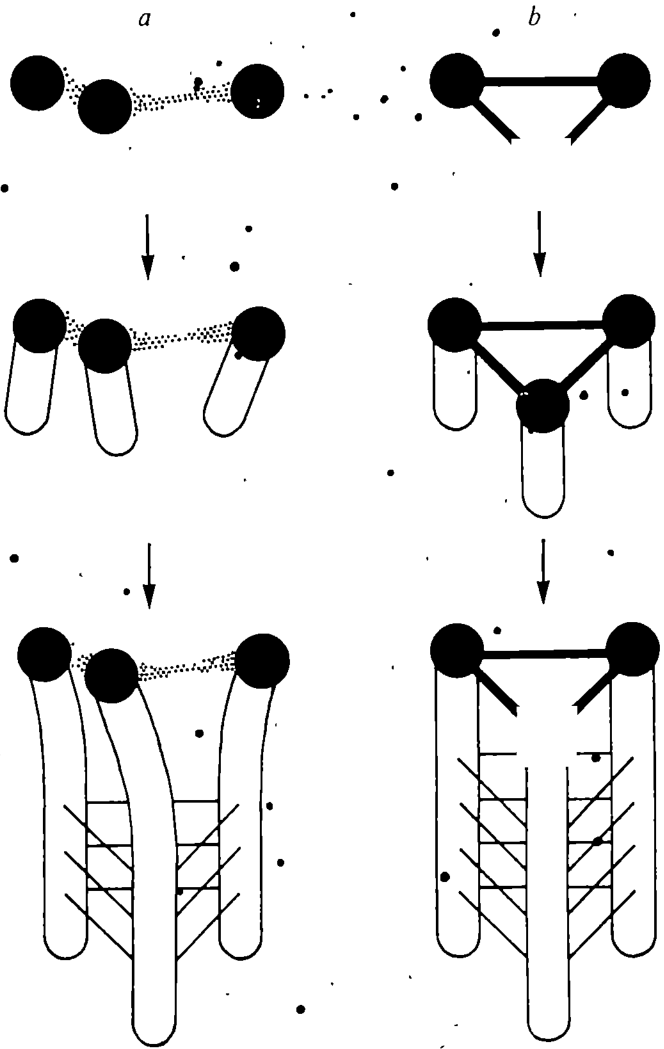

Fig. 2 Establishment of microtubule packing *a*, The nucleating elements (black spheres) are not precisely arranged Microtubules self-link into a regularly spaced arrangement *b*, The nucleating elements are bound together to form an MTNT which defines the arrangement of the tubules before they are connected together by links

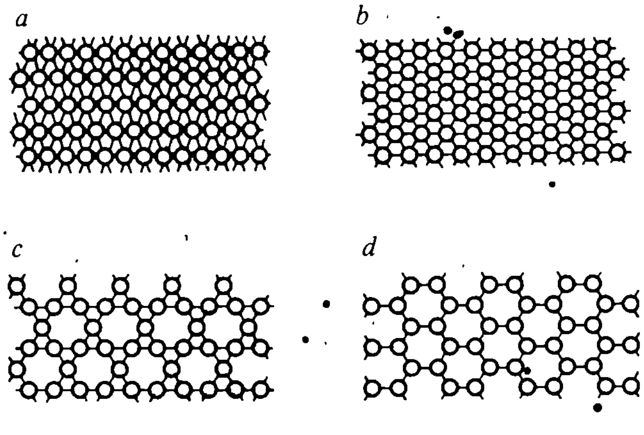
Fig. 1 Equivalent patterns of tubule packing and linkage as revealed in cross-sections of tubule bundles. *a*, Nemadesma in the flagellate *Entosiphon*[30], *b*, nemadesma in the ciliate *Nassula*[28], *c*, axoneme in the radiolarian *Sticholonche*[31]; *d*, axoneme in the heliozoan *Raphidiophrys*[24]



Establishment of pattern

Patterns of microtubule packing in tubule bundles seem to be established in two main ways[9,24,28] For some bundles, pattern seems to be defined by self-linkage[9,28] when intertubule links connect adjacent tubules together. Links are usually peg-shaped structures with lengths of up to 40 nm and diameters of 3–7 nm. They are probably made up of protein subunits. The nexin-links of cilia are largely composed of protein subunits (molecular weight 150,000)[29], but no other details of the molecular composition of any other types of links are available. In several types of microtubule bundles most of the tubules are linked together in an equivalent fashion so that a repeating lattice of tubules and links is apparent when cross sections of the bundles are examined (Fig. 1). Such patterns may be established by self-linkage (Fig. 2*a*). This could be the case provided that the lengths of the links, and the positions and orientations at which they bind to tubule walls are precisely specified. At least some of these specifications are made in certain instances[28,32,33]. Analysis of axoneme assembly in certain heliozoans reveals that the pattern of tubule packing is established after nucleation of tubule assembly in a way which indicates that self-linkage is responsible[24,34].

A distinctly different procedure seems to establish pattern during assembly of certain other bundles. Pattern seems to be determined by a pre-existing arrangement of nucleating elements before tubule assembly begins because tubules are precisely positioned when they first start to assemble[14,28,35]. An MTOC in which nucleating elements are bound together in a highly ordered arrangement before they initiate tubule assembly is termed a microtubule-nucleating-template (MTNT) (ref. 28). There is no reason why such a template should not self-assemble from proteins coded for by chromosomal genes in the absence of any pre-existing copies of the template; these templates need not be regarded as genetically autonomous self-replicating entities. Although the pattern of microtubule packing is apparently maintained by self-linkage as tubules grow out from an MTNT (Fig. 2*b*), there may be advantages in assembling an MTNT to establish certain types of microtubule patterns and these are considered in the sections which follow.

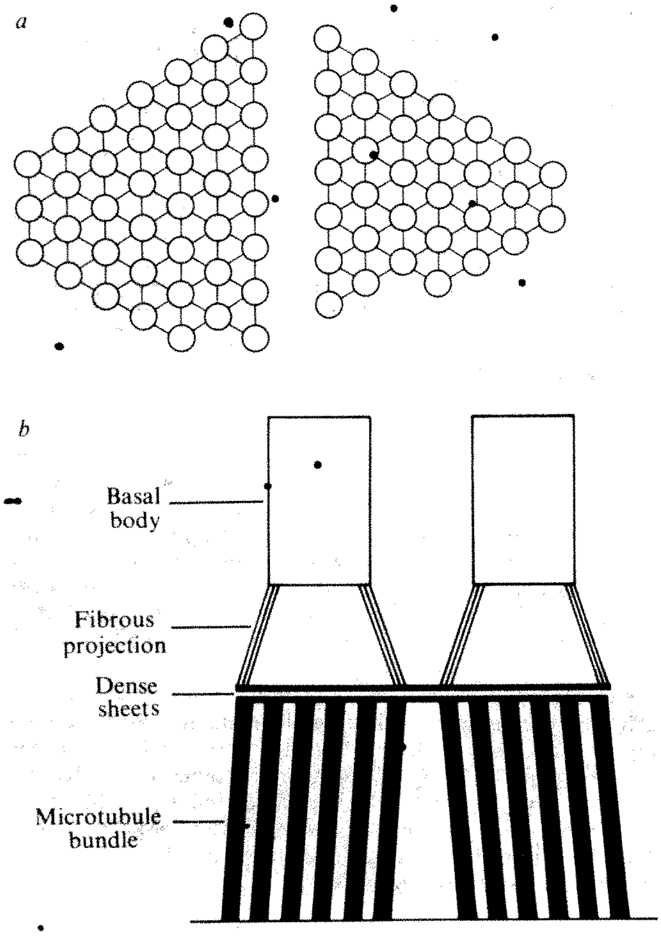


Fig. 3 The paired microtubule bundles of the ciliate *Urotricha*. *a*, Tubule arrangement and cross-sectional shape of a bundle pair based on micrographs of *U. faurei*[36]. *b*, Lateral view of the upper portions of a pair of bundles in *U. ovata*[37] showing attachment to basal bodies.

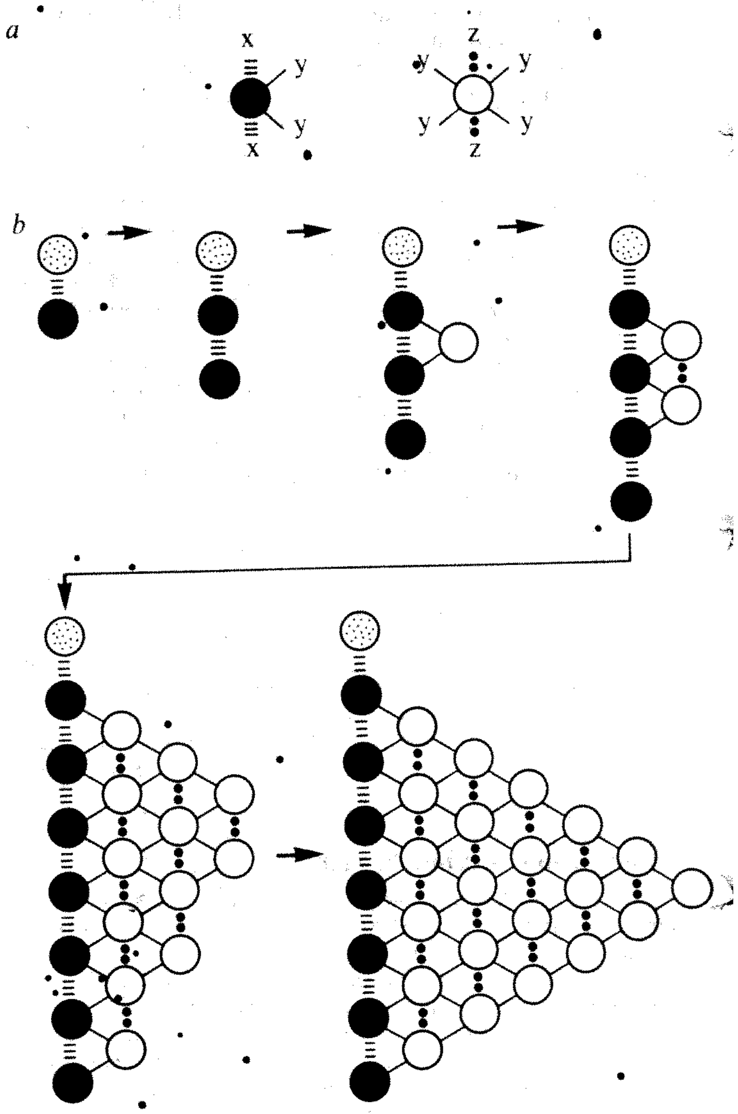

Fig. 4 A model scheme for assembly of a triangular MTNT. *a*, Schematic representation of the two types of nucleating elements required showing the arrangement of their binding points which lie in the same plane and can only bind to points of the same type on other elements. *b*, Stages in the assembly of elements to form the MTNT on a basal body projection. Each basal body which is attached to the top of a bundle has a projection (stippled) which bears an x binding point. An x bond can form between a basal body projection and any black element which is not already bound to any other element, and can also join two black elements provided one of the elements is already bound to another black element or a basal body projection. The y bonds can only join unbound or 'free' white elements to two other elements (black or white) which are already bound together so that two y bonds can form simultaneously when binding is effected. A z bond forms when both of the white elements it is to connect are already joined to the template by y bonds.

Triangular shape specification

The cytopharyngeal microtubule bundles (nemadesmata) of certain ciliates have rather precisely defined cross-sectional shapes although their tubules are apparently linked together in an equivalent hexagonal fashion. For example, in *Urotricha* the bundles have cross-sectional profiles which closely approximate to equilateral triangles in shape. Furthermore, bundles are closely juxtaposed in pairs and their cross-sectional profiles are precisely oriented with respect to each other (Fig. 3*a*). The tops of each of the bundles in a pair are attached to two sheets of dense material which are connected by fibrous projections to the proximal ends of a pair of basal bodies (Fig. 3*b*). No information is available about the sequence of events which occurs during bundle morphogenesis in *Urotricha* but in related ciliates the tubules of similar bundles grow out from dense sheets attached to basal bodies[25,38].

Specification of the cross-sectional shape and orientation of a bundle is most readily accounted for in theory by assuming that an MTNT forms by the assembly of two types of nucleating elements. If the conditions outlined in Fig. 4 are satisfied assembly of a triangular template will proceed along the lines indicated. The steric conformation of the elements and their binding points must be such that binding always results in all y bonds projecting from the same side along the row of black elements, and such that the points on the surfaces of the elements where nucleation of tubule assembly starts are all facing in the same direction (perpendicular to the lower surface of the template which faces away from the basal body). If the number of black elements available for assembly is limited, this number will largely determine the size of the template even when an excess of white elements is present. In these conditions the assembly scheme is a closed one like that for the coats of icosahedral viruses[39]. The orientation of the cross-sectional profiles of adjacent bundles with respect to each other may be determined by pre-existing spatial information in the form of precise orientation of the two basal bodies and their projections. There is considerable evidence that adjacent basal bodies in the ciliate cortex are often oriented with this degree of precision[40].

An important feature of the use of an MTNT in the situation described above is that all the bundle tubules can be identical. Each tubule would be potentially capable of linking to six neighbours hexagonally arranged around it. The extent to which this potentiality is realised depends on the number of neighbours specified by the MTNT. The possibility that triangular shaping could be established by self-linkage of two types of tubules along the lines suggested above for nucleating elements cannot, however, be excluded. Nevertheless, it is difficult to see how two types of tubules bound to sheets of dense material could have sufficient freedom of movement to self-link and form adjacent bundles with triangular cross sections oriented with respect to each other, unless tubule positions are specified fairly exactly by an MTNT at the start of tubule assembly.

Hollow axonemes with circular cross sections

The circular arrangement of microtubules in the axonemes of cilia and flagella is established at the beginning of basal body morphogenesis when exactly nine tubule triplets start to assemble in a regular circular arrangement. In *Paramecium* the sequence shown in Fig. 5 seems to occur. The dense disk may be an MTNT with nucleating elements bound in an evenly spaced circular arrangement around its perimeter. It is possible, however, that links can act as nucleating elements in this and certain other situations. When, and if this ever occurs, unlike a self-linkage procedure, tubule position is determined when tubule assembly is nucleated. For example, there may be only one nucleating element on the disk. Each of the links may be able to bind at one end at a particular orientation to certain points on existing A tubules and when it has done so nucleate assembly of a new tubule at its other end. Such a scheme accounts for the sequence of basal body tubule assembly which also occurs in several other organisms besides *Paramecium* (ref. 42). In some of these other organisms, however, a cartwheel structure with a hub and nine evenly spaced radial spokes is apparent before any of the tubules can be detected. These cartwheels may act as MTNTs if the tip of each spoke nucleates assembly of a tubule triplet[43,44]. Tubules and/or nucleating elements also seem to become grouped around a central non-microtubular structure during initial stages in the assembly of some other types of hollow axonemes which are circular in cross section. For example, when assembly of tentacle axonemes in the suctorian *Choanophrya* begins, tubules take up positions around a cylindrical 'condensation centre'[45]. This centre breaks down later in axoneme development when the circular tubule array is complete and tubules are joined together by links.

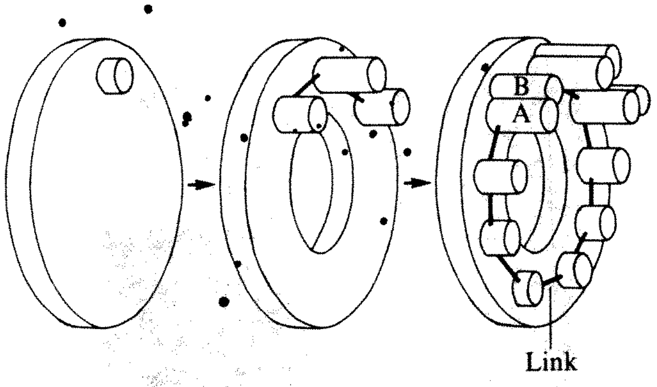

Fig. 5 Schematic diagram showing early stages in basal body assembly in *Paramecium* (ref. 41). One of the A tubules of a basal body starts to assemble shortly before the other eight. A second and third A tubule then assemble on either side of the first one and this sequence continues until a closed circular array has formed. Links connect tubules together at an early stage of their assembly and disappear shortly after the circular array is complete. The tubules grow out from a flat dense structure which is initially disk-shaped and then becomes hollowed out at its centre. Addition of the B tubule components of each triplet to A tubules starts before all the A tubules have formed.

The arrangement adopted by microtubules in sperm tails of the coccid insect *Planococcus* provides an example of a situation in which a rather precise microtubule configuration may be generated simply by crowding tubules closely together around a cylindrical structure without the assembly of an MTNT or very precise control of tubule linkage. During outgrowth of sperm tail axonemes in this and certain other coccids, microtubules are closely packed (sometimes into an approximately hexagonal array) around a cylindrical core of chromatin and other dense material[46,47]. In *Planococcus* two concentric tube-shaped arrays of microtubules are arranged around the dense core. A curved sheet-like array is usually situated inside the completely tubular ones and the dense core is often slightly indented where this array lies against it. One way in which this arrangement could be established, in this case by a 'close packing effect', is shown in Fig. 6. Examination of other microtubule bundles also indicates that patterns of microtubule packing which are hexagonal or nearly hexagonal, and certain types of dislocations in such arrays, may be established and/or maintained by a close packing effect[28,48]. The origin and

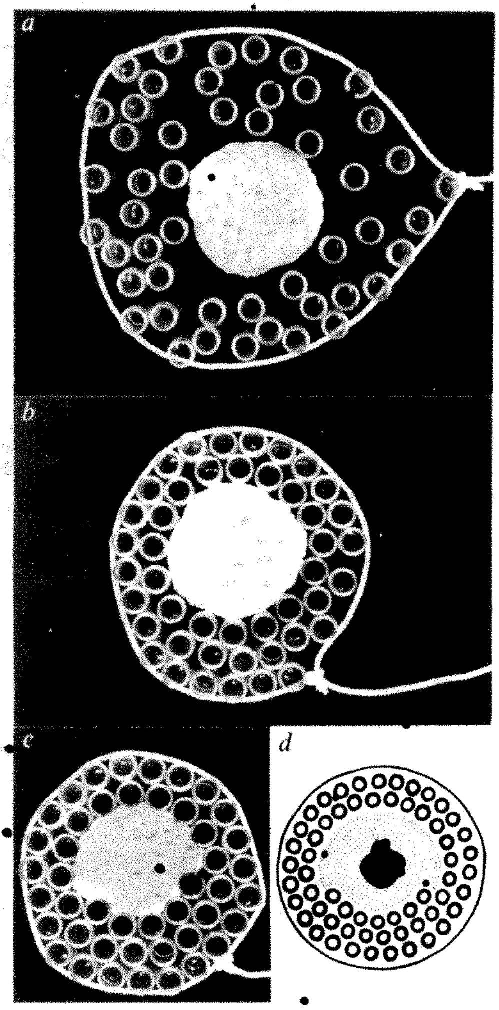

Fig. 6 Microtubule positioning in sperm of the coccid insect *Planococcus citri*. *a*, Dynamic model showing how tubules may be closely packed around a central cylinder of spongy material. Unstoppered glass specimen tubes stand on a smooth surface and are positioned fairly evenly around a cylinder of artificial sponge (the same height as the tubes). *b*, A string lariat is tightened and the tubes pack closely around the sponge. *c*, As tightening continues two circular arrays of tubes are formed and an inner curved sheet-like array presses into the sponge to produce an indentation like that in the dense core of the sperm. *d*, Diagrammatic cross section of a sperm based on electron micrographs[47]. Microtubules are arranged around a core of chromatin (black) and other dense material (stippled).

nature of the forces which might be involved in packing the tubules closely together in such situations are unknown.

Non-equivalent packing patterns

More complex events than any of those considered above may be involved during the assembly of microtubule bundles in which tubules are not all linked together in an identical fashion[8,34]. For example, in axonemes of centroaxoplastid radiolarians approximately two thirds of the tubules are linked to two neighbours, the others are linked to three[31]. In some such instances, the number of tubules in a bundle is exactly defined[49]. Descriptions of the assembly sequences for most bundles with 'non-equivalent' patterns of tubule linkage are not yet available. It is not clear whether all the tubules in these bundles are identical so that MTNTs are required to establish pattern, or whether pattern is generated when tubules of two or more types self-link. Greater freedom of movement will be required for tubules of two or more types to self-link than when only one type of tubule is involved. Can tubules of two or more types be confined in a localised region of cytoplasm and still have sufficient freedom of movement to effect self-linkage? A non-equivalent pattern of tubule packing seems to be established by self-linkage during generation of the double-spiral pattern in axonemes of the heliozoan *Echinosphaerium* (ref. 34). In this organism, however, tubules may be free to diffuse through the cytoplasm more extensively than is usually the case because the number, size, and spacing of axonemes does not seem to be very precisely defined. In addition, the suggestion[50] that relatively long-range allosteric interactions take place between adjacent tubules through their links during self-linkage raises the possibility that tubules which are initially identical can self-link in a non-equivalent fashion.

More information about the molecular composition of nucleating elements, intertubule links and MTOCs will facilitate further understanding of spatial control during assembly of microtubule bundles. Progress in this field is also impeded by our ignorance of the ways in which links bind to tubules. Whether they bind directly to tubulins or to other proteins[51–53] which may be bound to tubule walls is unknown. There are indications that in certain flagellar microtubules some of these proteins are mainly associated with particular protofilaments (rows of tubulins) along one side of each tubule[53]. Such unilateral protein arrangements may help to specify patterns of link attachment.

I thank Dr D. H. Lynn for criticism, and the SRC for grants.

Chemical modification of DNA polymerase phosphoprotein from avian myeloblastosis virus

Chris M. Tsiapalis*

Life Sciences Research Laboratories, 1509½ 49th Street South, St Petersburg, Florida 33707

Fractionation of purified avian myeloblastosis virus DNA polymerase, after phosphorylation in vitro, *revealed the presence of a small acidic protein, a phosphate acceptor polypeptide with high specific activity. Its presence in the phosphorylated form with the polymerase resulted in as much as a 10-fold increase in the rate of DNA synthesis. Its presence in the dephosphorylated form with the polymerase had no effect in the rate of DNA synthesis.*

Since the recognition of an RNA-dependent DNA polymerase (RDDP) in RNA viruses[1-3], much effort has been expended on studies of its structure and function[1-11]. Two polypeptides, α and β, with molecular weights of 60,000 and 100,000, respectively[5-8], are generally demonstrable in preparations of RDDP from avian myeloblastosis virus (AMV). But the existence of the separate components and/or interrelationships between them remain obscure. The work reported here has revealed a constituent which appears in preparations of the highly purified RDDP activity isolated from AMV. This material has the properties of a nondialysable, small, acidic phosphoprotein, designated φ, which can be phosphorylated by a highly purified AMV protein kinase *in vitro*. Demonstration of φ is based on the separation of phosphorylated φ from purified AMV-RDDP by three different methods: (1) molecular sieving on Sephadex G-200; (2) isoelectric focusing on polyacrylamide gels, and (3) the use of sodium dodecyl sulphate–polyacrylamide gels. In addition, differences in the influence of phosphorylated and dephosphorylated φ on the rate of DNA synthesis by the polymerase are documented here. Finally, implications with respect to possible chemical modification of AMV-RDDP as a regulatory mechanism in the life cycle of the virion and its behaviour in the process of replication observed *in vitro* are discussed.

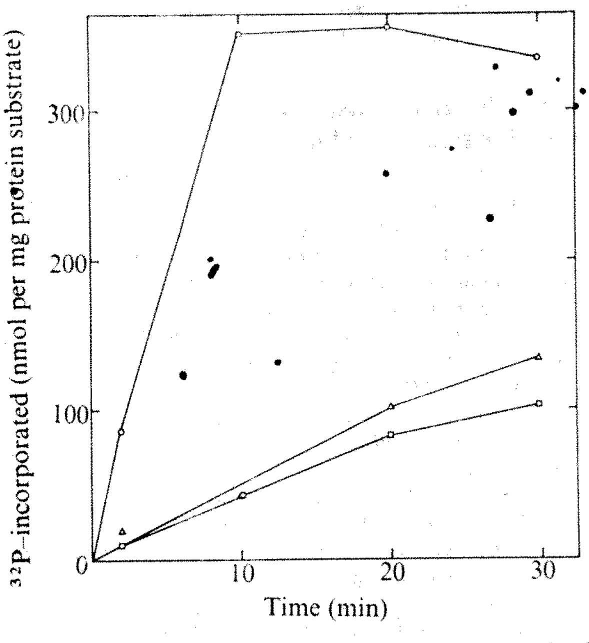

Fig. 1 AMV protein kinase-catalysed phosphorylation in the presence of γ-^{32}P-ATP and protein substrates of viral and non-viral origin. A 20-fold standard reaction mixture of AMV protein kinase was prepared containing 25 mM Tris-Cl (*p*H 8.3), 20 mM $MgCl_2$, 10 mM dithioerythritol (DTE), 20 mM KCl, 0.02% (v/v) Triton X-100, 0.2 mM γ-^{32}P-ATP (475 c.p.m. per pmol), and 20 µl of AMV protein kinase[12]. The amounts of phosphate acceptor protein per reaction were as follows: ○, 7 µg of purified AMV-RDDP, △, 200 µg of partially purified AMV-RDDP; □, 2,500 µg of α-casein (Sigma). The reaction was carried out at 35 °C. At the times indicated, 10-µl samples were placed on GF/C disks and treated as described before[21]. Radioactivity was determined in a Packard Tricarb liquid scintillation spectrometer and converted to nmol of ^{32}P incorporated per mg of protein substrate.

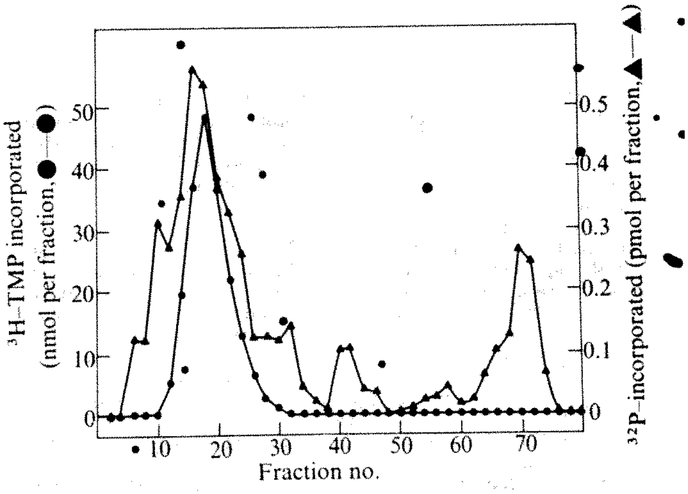

Fig. 2 Chromatographic analysis of AMV polymerase after phosphorylation with AMV kinase[12]. At the completion of the protein kinase reactions described in Fig. 1, all reaction products were dialysed against buffer A (200 mM potassium phosphate (*p*H 7.2), 0.1 mM EDTA, 2 mM DTT, 0.2% Triton X-100 containing 10% glycerol) for 36 h with four changes of buffer to remove γ-^{32}P-ATP. 0.5 ml (a fourth of the protein kinase reaction with purified AMV-RDDP as the phosphate acceptor) was subjected to chromatography by molecular sieving on Sephadex G-200 (1.6 × 60 cm) equilibrated with buffer A. Fractions of 1.8 ml were collected and analysed for ^{32}P-radioactivity (▲) as described in Fig. 1. RDDP activity (●) was determined after incubation for 60 min at 35 °C of a 10-µl sample with 50 µl of RDDP standard reaction mixture (50 mM Tris-HCl (*p*H 8.3), 0.5 mM ^{3}H-TTP (16.6 c.p.m. per pmol), 6 mM $MgCl_2$, 0.2 mM poly(A)$_n$·dT$_{12-18}$(10:1), 40 mM KCl, containing 100 µg of bovine serum albumin per ml), with 50-µl samples from each reaction placed on GF/C disks and treated as described before[21].

Phosphorylation of polypeptides and separation of φ

The kinetics of the phosphorylation reactions presented in Fig. 1 are expressed as incorporation of radioactivity from γ-^{32}P-ATP per mg of protein used as the phosphate acceptor in that reaction. All phosphorylation reactions described here

---

*Present address: Meloy Laboratories Inc., 6715 Electronic Drive, Springfield, Virginia 22151.

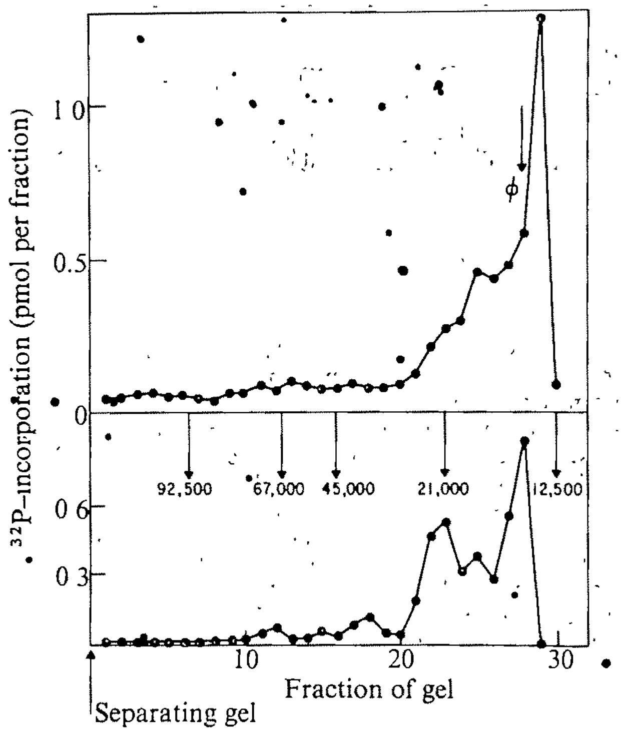

Fig. 3 Sodium dodecyl sulphate–polyacrylamide gel electrophoretic profiles of ^{32}P-radioactivity and standard proteins. Electrophoresis in the presence of 0.1% sodium dodecyl sulphate was carried out on columns (6 × 120 mm) of 15% polyacrylamide separating gel, including 6% polyacrylamide stacking gel as described by Laemmli[23] Protein samples were precipitated at 4 °C by addition of trichloroacetic (TCA) and (final concentration 10%), collected by centrifugation (20,000*g*, 20 min), washed with acetone and suspended in sample buffer. When β mercaptoethanol was added, samples were heated for 2 min to 100 °C to dissociate metastable aggregates and a 0.3-ml sample was applied to each polymerised gel. Electrophoresis was carried out at 60 V until the sample passed the stacking gel, and was then increased to 120 V for about 5 h at 18 °C. In gels intended for staining, the proteins were precipitated during 1 h at 60 °C with 14% TCA, and the gels were then washed at room temperature with 10%, 5% and 3% TCA within 24 h. These gels were then stained in a 0.05% solution of Coomassie brilliant blue R-250, in a mixture of methanol–acetic acid–water (45:9·46) during 2 h, followed by washing in the same solvent until the background was colourless. The gels were then placed in 9% acetic acid to reswell, after which they were photographed and/or traced Gels intended for measurement ^{32}P-radioactivity distribution, were sliced (collecting three slices per fraction) and solubilised, and radioactivity distribution determined as described before[24]. The molecular weight of AMV-polypeptides was calculated from their migration relative to proteins of known molecular weight, as described[25]. Upper graph, migration of ^{32}P-radioactivity distribution from an aliquot of IEF pool 1 (which focused with an average *p*I of about 4) Lower graph, standard proteins; phosphorylase α (92,500 daltons), bovine serum albumin (67,000 daltons), ovalbumin (45,000 daltons), ^{32}P-α casein (21,000 daltons) and cytochrome *c* (12,500 daltons). In addition, the distribution of ^{32}P-radioactivity from an aliquot of IEF pool 2 (which focused with an average *p*I of 7 0–7.5 in association with RDDP).

were carried out with our most purified fraction of AMV protein kinase[12].

On the basis of values of nmol of ^{32}P-incorporation per mg of protein substrate present in the non-viral and viral polypeptides examined, one of the virion polypeptides φ found in association with our most purified RDDP fraction displayed the greatest specific activity of phosphorylation (Fig 1 and ref. 12).

Fractionation, by molecular sieving on Sephadex G-200 (Fig. 2), of an aliquot from this protein kinase reaction, in the presence of our most purified RDDP (Fig. 1), followed by measurement of the distribution of RDDP activity, and ^{32}P-radioactivity, revealed that about 82% (Fig. 2 fractions 10–25) of the total ^{32}P-radioactivity on the column coincided with the RDDP activity. Most of the remaining ^{32}P-radioactivity eluted just behind myoglobin (fractions 65–75). Fractionation by isoelectric focusing on polyacrylamide gels[12] of another aliquot used for gel filtration as above, followed by measurements of the distribution of RDDP activity and ^{32}P-radioactivity, revealed that most of the ^{32}P-radioactivity on the gel focused with an average *p*I of about 4.0. The remaining ^{32}P-radioactivity on the gel focused with an average *p*I of 7.0–7.5 in association with RDDP (ref. 12).

Isoelectric focusing of the enzyme resulted in considerable losses of RDDP activity. Incomplete dissociation of φ protein from RDDP proteins is due to intramolecular salt link(s) between the phosphorylated (anionic) site(s) of φ and neighbouring basic (cationic) amino acid(s) of RDDP α and/or β polypeptides, since in high salt complete dissociation resulted[12]. Furthermore, in denaturing conditions (Fig. 3), complete dissociation of φ protein from α and β polypeptides was demonstrated (see later).

Electrophoresis of a sample identical to those used for gel filtration and isoelectric focusing revealed (Fig. 3) that all the ^{32}P-radioactivity migrated faster than α casein and slower than cytochrome *c* (Fig. 3, upper graph). No detectable radioactivity was observed in the regions of the gel where α and β polypeptides from purified RDDP would be expected with molecular weights of about 60,000 and 100,000 respectively. On the basis of the distance of migration of several marker proteins (Fig. 3, lower graph), the phosphoprotein (φ) found in association with purified RDDP was estimated to have a molecular weight of about 15,000. Although these results demonstrate association of φ with purified RDDP and complete dissociation of φ from RDDP, they do not exclude the possibility that φ is produced by limited proteolysis of the RDDP real enzyme (holoenzyme) at some time in the life cycle of virions and/or during purification[13-16].

Effect of *in vitro* phosphorylated and dephosphorylated φ

Purified AMV-RDDP was incubated for 30 min at 4 °C in the absence and presence of a preparation of purified phosphorylated ^{32}P-φ. Aliquots of each sample were then used to measure rates of ^{3}H-dGMP incorporation directed by poly(C)$_n$·dG$_{12-18}$ at the times indicated (Fig. 4*a*). In the presence of phosphorylated φ, the rate of poly(C)$_n$ dG$_{12-18}$-directed, ^{3}H-dGMP incorporation increased as much as 5–10-fold (Fig. 4*a*) Addition of larger amounts of phosphorylated φ, however, inhibited the rate of ^{3}H-dGMP incorporation (results not shown) When phosphorylated φ was added to purified AMV-RDDP reactions directed by poly(A)$_n$·dT$_{12-18}$ (Fig 4*b*) or AMV RNA·dT$_{12-18}$ (Fig. 4*c*), the rates of polymerisation increased but not as much.

Dephosphorylated φ was made as described in Fig. 5. Most purified AMV-RDDP was incubated for 30 min at 4 °C in the absence and presence of dephosphorylated φ together with the controls designated in Fig. 5. Removal of P$_i$ from φ eliminated the observed stimulatory effect of phosphorylated φ (Fig. 4). This is taken to mean that AMV phosphoprotein phosphatase has essentially completely dephosphorylated φ In other experiments on the dephosphorylation of φ with alkaline phosphatase or AMV phosphoprotein phosphatase, incomplete dephosphorylation was observed (results not shown). The influence of phosphorylated and dephosphorylated φ on the rate of acid solubilisation of ^{3}H-poly(A)$_n$ by purified AMV-RDDP from the hybrid homopolymer ^{3}H-poly(A)$_n$·poly(dT)$_n$ has been examined and the results will be reported elsewhere.

Implications

My results are relevant to several questions about the nature of RDDP. (1) What polypeptide(s) constitute the real enzyme? Reported results[7-9,15] support the notion that one of the two polypeptides (α) with a molecular weight of about 70,000 from

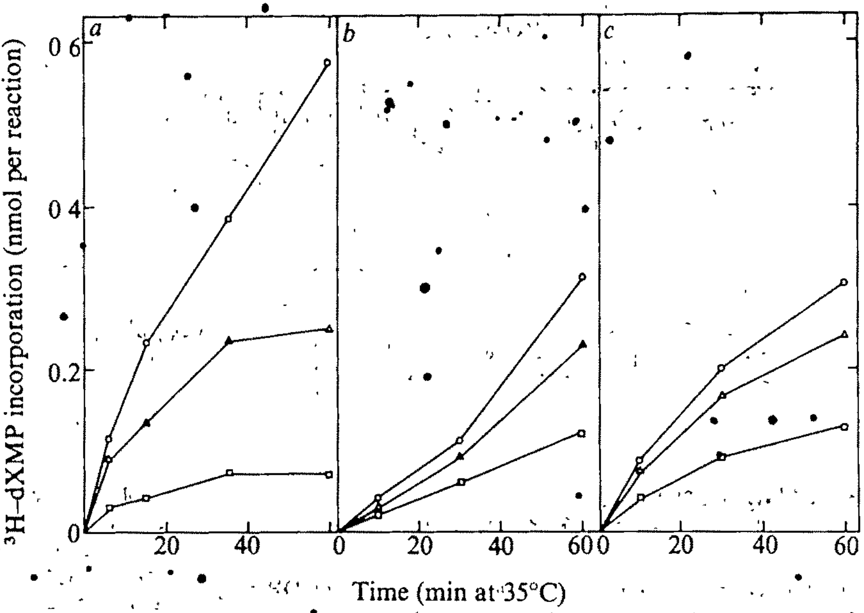

Fig. 4 Incorporation of radioactivity by a purified fraction of AMV-RDDP in the absence and presence of φ. 66 ng of the enzyme was incubated in the absence and presence of 2 µl and 5 µl of φ at 4 °C for 30 min, and all samples were made up to 12 µl with buffer A. After 30 min of pre-incubation of the above samples, 5-µl aliquots were added each to a 100 µl of the reaction mixtures described below and incubated at 35 °C for the time designated. *a*, ^{3}H-dGMP incorporation directed by 0.2 mM poly(C)$_n$. dG$_{12-18}$. *b*, ^{3}H-TMP incorporation directed by 0.2 mM poly(A)$_n$.dT$_{12-18}$. The homopolymers above were at a molar ratio of 10 adenosine to 1 thymine, and 10 cytidine to 1 deoxyguanosine, respectively. *c*, ^{3}H–TMP incorporation directed by 14.8 A_{260} AMV RNA per reaction in the presence of 0.2 mM dT$_{12-18}$ At the times indicated, 10-µl aliquots were placed on GF/C disks, treated, and the rates of ^{3}H-XMP incorporation were determined as described in Fig. 2. □, AMV-RDDP activity in the absence of φ, △, in presence of 2 µl φ; ○, in presence of 5µl of φ

AMV is a proteolytic degradation product[8,15,34], from (β) polypeptide which has a molecular weight of about 110,000. This possibility is supported by demonstrations that animal viruses contain proteinase activity involved in the cleavage of precursors of polypeptides (similar to those) found in the mature virions[13-16]. Specific proteolytic degradation has also been demonstrated with several DNA and RNA enzymes in prokaryotes[17-20]. (2) Why is the DNA product small[4-10]? Published reports[1-11], show that something was missing from the enzyme preparations used in previous studies. In 1972 Leis and Hurwitz described the isolation and characterisation of a heat labile, nondialysable factor from AMV that stimulated DNA synthesis, but no further studies have been reported. (3) Why does AMV-RDDP exhibit low fidelity when copying a variety of polynucleotide templates[11]? The high error rate of AMV-RDDP has been attributed to the nature of the polymerase[11]. Mizutani and Temin[34], however, have emphasised the importance of the reaction conditions in determining error-prone DNA polymerases in cell-free studies, and have suggested that changes in the physiological environment or altered DNA polymerases are responsible for the high mutation rates observed[11]. The results reported here support the suggestion that altered DNA polymerases in the life cycle of the virion and/or during purification are responsible for the high-infidelity observed[11,34]. This possibility can be tested by examining the influence of φ on the fidelity of AMV-RDDP enzyme in a cell-free system.

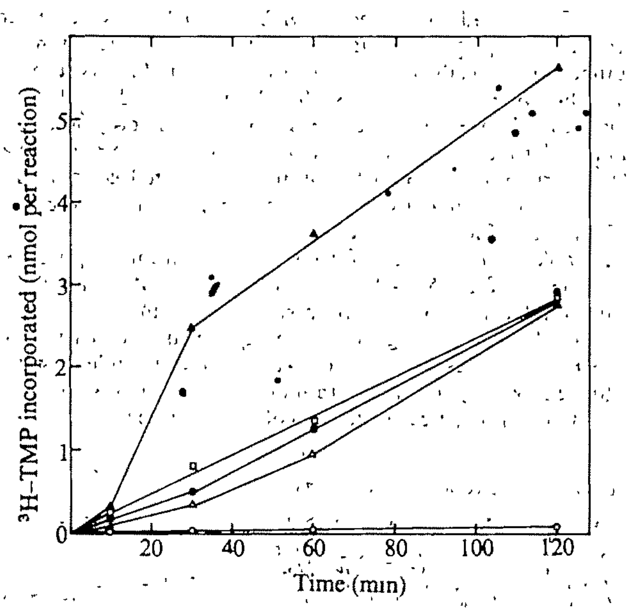

Fig. 5 Incorporation of radioactivity by a purified fraction of AMV-RDDP, in the absence and presence of phosphorylated and dephosphorylated φ. Dephosphorylated φ was made as described below. 3.5 µg of the enzyme was incubated for 30 min at 4 °C as indicated below, and all samples were made up to 60 µl with buffer A. After 30 min of pre-incubation, all samples were placed in ice and 10µl of each was added to 100 µl of the standard RDDP reaction mixture as described in Fig. 2, and incubated at 35 °C for the time designated. At the times indicated, 20-µl aliquots were placed on GF/C disks, treated, and the rates of ^{3}H-TMP incorporation were determined as described in Fig. 2. △, AMV-RDDP alone; ▲, AMV-RDDP in presence of ^{32}P–φ; □, AMV-RDDP in presence of dephosphorylated φ; ○, dephosphorylated φ alone; ●, AMV-RDDP in presence of bacterial alkaline phosphatase. Phosphorylated φ that had been dialysed to remove orthophosphate against Tris buffer was dephosphorylated with 20 µg of alkaline phosphatase in Tris-HCl (50 mM, *p*H 8.0) and MgCl$_2$ 5 mM). Dephosphorylation was carried out for 30 min at 35 °C. A sample equivalent to 5 µl of the phosphorylated φ and 5 µl of the phosphorylated φ were used in each case.

Fig. 7 A model to account for the relatively small size (5–10S) and unfaithful nature of the products observed with AMV-RDDP and other oncornaviruses. *a*, Forms I and IV of AMV-RDDP (see Fig. 6) contain φ a large oligophosphoprotein, which helps to maintain the template structure in the replicative form during DNA synthesis. *b*, Forms II and III of AMV-RDDP (see Fig. 6) contain the dephosphorylated form of φ, which permits the replicative nature of the template to convert into the collapsed form, by means of intramolecular hydrogen bonding[26].

Model of possible enzymatic modification of RDDP

The model shown in Fig. 6 predicts that AMV-RDDP may exist in four forms at some time in the life cycle of the virion and/or during purification of the polymerase. This is facilitated by the combination of three enzyme activities—phosphoprotein phosphatase, proteinase and protein kinase. Association of these activities with purified virions from avian myeloblastosis has been established (refs 12, 13, 14, 16, 27 and unpublished results). Form IV of AMV-RDDP is strongly supported by the results reported here. φ is the phosphate acceptor protein with the highest specific activity in a purified AMV-RDDP preparation (Figs 1–3). Whether φ and AMV-RDDP are ever covalently linked (AMV-RDDP form I) remains to be seen. The existence of form I of AMV-RDDP is so attractive that it requires further experimentation. Demonstration of the existence of form I will assist in the documentation of the possible existence of forms II and III. The results presented in Fig. 5 support the existence of form III. In addition, I have observed a difference in the stability between AMV-RDDP activity in lysates buffered with phosphate (no loss of activity in 48 h at 4 C) and lysates buffered with Tris-HCl (76% loss). Furthermore, when such lysates were subjected to isoelectric focusing, specific polypeptides from lysates buffered with phosphate had fIs more acidic than those observed in lysates buffered with Tris-HCl (ref. 37 and unpublished results).

I conclude that this is due to the inhibition of AMV phosphoprotein phosphatase[12] by phosphate, a potent inhibitor of phosphatases. Depending on the procedures used to purify AMV-RDDP and whether or not throughout purification and storage of the enzyme, the solutions are buffered with Tris-HCl or phosphate buffer, the amount of phosphorylated φ may vary considerably and thus influence the yields, properties and form(s) of the enzyme isolated. There is support for this in several published reports[30–33,37].

In this respect it is interesting that in enzyme preparations buffered with Tris-HCl throughout purification only 10–20% recovery was observed[30,31], whereas in enzyme preparations buffered throughout purification with phosphate, as much as 70–90% recovery has been reported[32–33,37]. It is also interesting that studies *in vitro* on the infidelity of AMV-RDDP were conducted with enzyme preparations maintained throughout purification and stored in solutions buffered with Tris-HCl (ref. 11). Furthermore, dephosphorylation of purified AMV-RDDP with alkaline phosphatase from *E. coli* resulted in a decrease in the rate of polymerisation[37]. Similar results have been reported with RSV-RDDP (ref. 28).

I propose a model of AMV-RNA replication which may account for the small size (5–10S) of the products[4–10] and infidelity of replication of RDDP (ref. 11). This is represented diagramatically in Fig. 7*b*. RDDP will replicate only when the polymerase (forms II or III, Fig. 6) is present because φ is dephosphorylated in both these forms, so that the template exists in the collapsed form by means of intramolecular hydrogen bonding[26]. In contrast, Fig. 7*a* shows the replicative form of RNA in the presence of AMV-RDDP forms I or IV. This is made possible by the presence of the phosphorylated φ, which helps the template to remain so, while the polymerase makes the complete and faithful cDNA. One of the predictions in this model (Fig. 7*a*) has far-reaching implications concerning the size and fidelity of the polymerase product. In appropriate conditions, AMV-RDDP form IV, which can now be made available, may be able to make complete and faithful copies of the RNA from these virions.

The activity of RDDP from murine and simian C-type RNA viruses in the presence of phosphorylated φ increased by as much as 10-fold. No increase in the DNA polymerase activity from *E. coli* and *Mucrococcus luteus* could be detected in the presence of phosphorylated φ (C.M.T. in preparation). A comparable specificity of bacterial protein factors towards their homologous polymerase has been reported[38]. The pronounced enhancement observed on the rates of polymerisation catalysed by the polymerases from avian, murine and simian RNA viruses in the presence of phosphorylated φ, implicates φ as an important constituent in the replication of the genetic information of RNA viruses.

I thank Dr J. W. Beard for encouragement and support, Dr G. E. Houts for AMV-RDDP fractions and Mr Gary Hardy and Mrs Dorothy Beard for assistance in obtaining virus. I also thank Dr J. T. August for preprints of his manuscripts on FV3 protein kinase. This study was conducted under contract within the Virus Cancer Program of the NCI. I thank Professor F. J. Bollum for critical evaluation of the manuscript.

The structure of the combining site of the DNP binding IgA mouse myeloma protein MOPC 315 has been determined by a combination of high resolution nuclear magnetic resonance, electron spin resonance, model building and chemical modifications. This approach yields the general dimensions of the site, its polarity and asymmetry features, the assignment of the DNP-contact residues and their three-dimensional coordinates.

ONE of the central problems in immunochemistry is the structural basis of antibody specificity, how does such a high diversity in molecular recognition reside in what seems to be a family of proteins closely related in their chemical structure? Recent progress in X-ray analysis of Fab′ fragments of homogeneous myeloma proteins has led to the elucidation of the three-dimensional structure of the binding site of two antibodies, the human protein New which binds vitamin K and the mouse protein McPC 603 which binds phosphorlycholine[1,2]. From these studies it is clear that the residues forming the sites that are complementary to the antigen are contributed by the hypervariable regions[3] (three segments of 5–10 residues each, in both light and heavy chain) and that replacements of amino acid residues in these segments will generate binding sites with new specificities. Such replacement will not disturb the 'immunoglobulin fold' of the variable domains which remain similar in all antibodies. Thus on a background of a common three-dimensional structure a vast number of specificities can be generated. This diversity in recognition is the essence of the immune system and therefore a comparative analysis of a large number of combining sites is required in order to provide the details of molecular recognition by antibodies[4]. It is also important to develop new methodologies by which the structure of the antibody site can be analysed in solution and yield information comparable with that obtained from crystal studies We describe here an attempt to elucidate the structure of the binding site of the DNP binding protein 315, a mouse IgA myeloma protein[5], by a combination of high resolution nuclear magnetic resonance (n.m.r.), electron spin resonance (e.s r.), model building and chemical modification. We show that by this approach it is possible to determine the general dimensions of the site, its polarity and asymmetry features and to assign the contact residues with the ligand, as well as their three-dimensional coordinates.

Model building as a basis for structural analysis

A quantitative comparison of the tertiary structure of human and mouse variable domains has demonstrated that the immunoglobulin fold is very similar in different variable domains while structural differences occur predominantly in the hypervariable loops which comprise the combining site[6] Hence the variable region can be regarded as consisting of a rigid framework to which are attached the hypervariable loops This provides a basis for comparative analysis of antibody combining sites by model building, which then uses the coordinates of the framework from X-ray analysis data of known immunoglobulins and the sequence of the immunoglobulin which is to be analysed. Considering the diversity of immunoglobulins and the impracticality of X-ray analysis of all interesting antibodies this model building approach is an attractive way for a comparative study of antibody combining sites, provided the resulting combining site and the binding of ligand to it can be tested by various physical methods. Some of the features of the combining site of protein 315 have already been indicated by Poljak on the basis of comparison with the structural model of protein New (ref. 7). More recently, Padlan *et al.*[8], have described the model building of the site of protein 315 on the basis of coordinates derived mainly from protein 603 and using also information from protein New. The resulting combining site[8] is presented in Fig 1 and is the subject of further refinement on the basis of the n.m r. data presented in this article. The main feature of 315 combining site is its hydrophobic nature. The clustering of hydrophobic residues is more extensive than in either protein 603 or New. The middle of the surface produced by the hypervariable loops is dominated by a pronounced cavity which can accommodate the dinitrophenyl ligand and the depth of this cavity is approximately 1.2 mm. Details of this combining site are discussed by Padlan *et al*[8]. At first sight it seems that there are several different modes of binding that can accommodate the ligand in it We shall demonstrate both that the n.m.r. results dictate an unique arrangement of the DNP ligand in the cavity of the protein 315 and can be used to refine the three-dimensional positions of various residues in the site. We have also probed that part of the combining site, which binds the side chain of DNP ligand by using homologous series of spin-labelled haptens or alkyl phosphonate derivatives of haptens.

Gross architecture of the combining site

Since approximately 50% of the binding energy of DNP ligands to protein 315 is contributed by the hapten side chain[9], it is of great interest to study the environment of

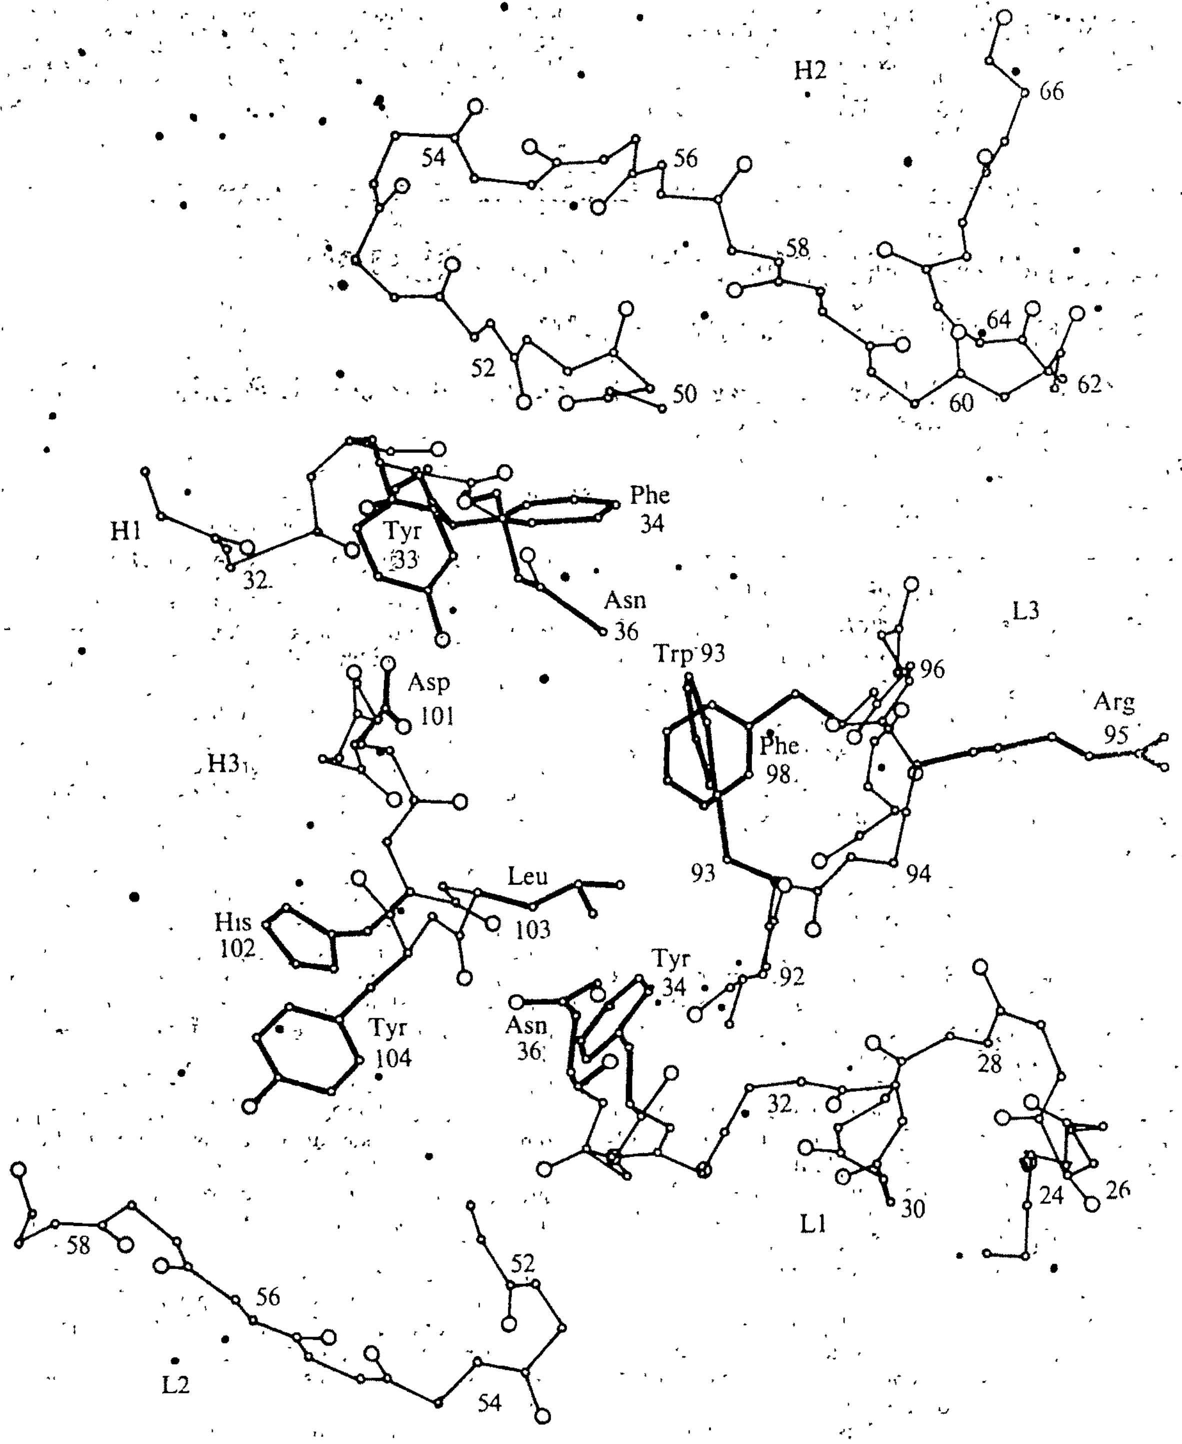

Fig. 1 The predicted combing site of MOPC 315 This has been obtained from the coordinates of Padlan *et al.*, which have been very kindly made available to us before publication. The hypervariable loops of the heavy (H) and light (L) chains and the hapten binding site are indicated.

the combining site in this area. To do this we have used two series of haptens of systematically increasing chain length with magnetic resonance probes attached. One series consists of either six- or five-membered nitroxide rings attached to the DNP moiety which is analysed by the e.s.r. spectra and the other series consists of alkyl phosphonate groups attached to the DNP moiety which are analysed by their phosphorus n.m.r. signals

The spin label mapping procedure involves comparison of the observed e.s.r. hyperfine splittings with those expected as a result of different postulated motions for the spin label. An indication of the type of analyses has been given previously for DNP ligands containing a six-membered nitroxide ring[10]. From that study, it emerged that the DNP ring is rigidly held in the combining site, that the depth of the site is 1.1–1.2 nm and that the minimum lateral dimensions at the entrance to the site are 0.6×0.9 nm. However, this method has now been extended to the analysis of five-membered spin-labelled haptens with chiral centres. Measurements of such haptens result in separate bound signals from each enantiomer[11] and this shows that the site is asymmetric with respect to the plane of the DNP ring. The two enantiomers which probe different sides of the site are restricted differently in their motions. Comparison of the experimentally measured values of the maximum hyperfine splittings, A_{max} with those calculated on the basis

Table 1 Deduction of lateral dimensions of the combining site by comparison of experimental values of the esr hyperfine splitting constants with those expected for possible motions of the five-membered spin label haptens as deduced from studies of molecular models.

Hapten	Allowed motion† (about the bond shown)	Spatial requirements for this motion (nm)† width	height	Calculated maximum value of hyperfine splitting constant for allowed motion	Observed maximum hyperfine splitting constant Enantiomer 1	Enantiomer 2
DNP-NH-CH$_2$ 	±40′	0.7	1.0	2.81	3 2	2.7
5-F-DNP-NH 	±20	0.6	0 9	3.1	3.0	2·63

† Calculated from atomic models.

of intrinsic allowed motions of these haptens (Table 1) assuming a rigid DNP ring leads to the determination of precise lateral dimensions These conclusions are summarised in Fig. 2.

Environment of hapten side chains

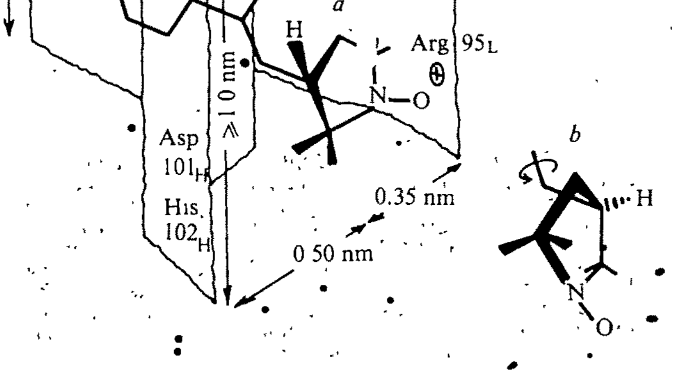
The polarity of the nitroxide radical's environment can affect the magnitude of the hyperfine splitting. The relatively large difference in A_{max} between the 'rigid' enantiomers of haptens V (3.2) and VI (3.0) (~0.2 mT, Table 1) is expected to arise from a polarity effect, that is the nitroxide of hapten V is probably close to a positive charge which results in a higher value of A_{max}. A positive charge 0.1–0.3 nm away from the NO and along its axis could account for the difference in the values of A_{max} (refs 12, 13) between the two haptens. The length and geometry of hapten V would then allow the positively charged residue to be placed as shown in Fig. 2 Reference to the predicted model (Fig 1) immediately suggests that this residue must be Arg 95$_L$, since hapten V is rigid and the NO lies along the axis of the DNP ring.

The use of ^{31}P magnetic resonance provides an additional and more powerful probe of electrostatic environment. Since the pK_a of a phosphonate grouping is extremely sensitive to neighbouring charges, changes in the ionisation state of ^{31}P groupings with pH can be relatively easily monitored by observation of the changes in ^{31}P chemical shifts The phosphonate grouping approximates to a hemisphere of radius 0.3 nm so that by using a series of side chains of different lengths it is possible to probe different areas of the combining site for positively and negatively charged groups.

The pK_a values of three TNP alkyl phosphonate haptens (methyl, ethyl and propyl) when either free in solution or when bound to the Fv have been measured from titrations of ^{31}P chemical shifts (at 129 MHz). Only the TNP propyl phosphonate has its pK_a significantly affected, being decreased by 0 8 unit (from 7.7 to 6.9) suggesting the proximity of positively charged group. Using molecular models the extended length of this hapten measured along the plane of the TNP ring is 1.2 nm. From the dimensions of the site obtained from the e s r. mapping studies this places the phosphonate grouping just beyond the entrance to the combining site and in a position to interact with the positively charged group detected by the e.s.r. studies. The pK_a mapping and the e.s.r mapping techniques are therefore complementary and reference to the model confirms that Arg 95$_L$ is the candidate for this positive charge in both cases. Lys 52$_H$ is another positively charged residue at the edge of the combining site as has been confirmed by affinity labelling with bromoacetyl DNP lysine[14]. However, consideration of the geometries of the Tnp phosphonate haptens and the affinity label indicate that the phosphonate ligands are considerably shorter and will not be able to interact with Lys 52$_H$. This further illustrates how different techniques can be used to probe different areas of the combining site.

The predicted model places one (His 102$_H$) out of the three histidines in the Fv fragment near the combining site His residues are particularly convenient to study by high resolution n.m.r. The pK_a values of the three histidine residues in the Fv fragment have found to be 5.9, 6.9 and 8 2 (ref 10). On hapten binding, only one His residue has its pK_a significantly affected, the pK_a being increased from 6.9 to 7.2–7.4 depending on the hapten side chains. The narrow linewidths of the His resonances of this histidine suggest that it is on the surface of the protein and readily accessible to solvent. Reference to the model suggests this can only be His 102$_H$ This means that the pK_a value of 5 9 can be assigned to His 97$_L$ since we have previously assigned a pK_a value of 8.2 to His 44$_L$ from the results of paramagnetic spin label difference spectroscopy[10] His 102$_H$

Fig. 2 The overall dimensions of the DNP binding site as determined by spin-label mapping. The two enantiomers of one of the five-membered spin-labelled haptens are shown Anomer a is rigidly immobilised but anomer b is free to undergo a restricted rotation as shown.



therefore provides a convenient marker of the edge of the site. His 102_H on the other hand cannot be the candidate for the positive charge discussed previously which is sensed by the spin labels and the phosphonate groups. This is because the pK_a of His 102_H is similarly affected by various DNP ligands regardless of their length or charge. Hence the change in His 102_H pK_a reflects local changes in its environment whereas Arg 95_L interacts specifically with charged groups of the hapten which have the appropriate length of the side chain.

The DNP binding site

The red shift in the optical absorbances of DNP ligands bound to protein 315 (ref. 5) and circular dichroism studies[16] indicate interaction between the DNP ring and a tryptophan residue. The complex formed between a DNP ligand and L-tryptophan was therefore used as a model for the DNP–Fv interaction in an n.m.r. analysis. The addition of varying amounts of DNP-aspartate into a 10 mM solution of L-tryptophan results in upfield chemical shifts of all the aromatic resonance. By appropriate titrations[16] estimates of the fully bound shifts of all the protons in the complex can be obtained. These are in the range 0.1–0.5 p.p.m. upfield. Replacing tryptophan by any of the other aromatic amino acids does not result in any observed shifts thus showing the specificity of the interaction between the DNP ligand and tryptophan. The upfield chemical shifts can be analysed in terms of ring current interactions[17–19] which relate the shift on a nearby nucleus to its position from the centre of its aromatic ring responsible for the shift. Since all the aromatic protons in this system are shifted upfield this immediately suggests that a stacking interaction is occurring. The structure of the DNP and TNP complex is then found by a computer search which tests all possible

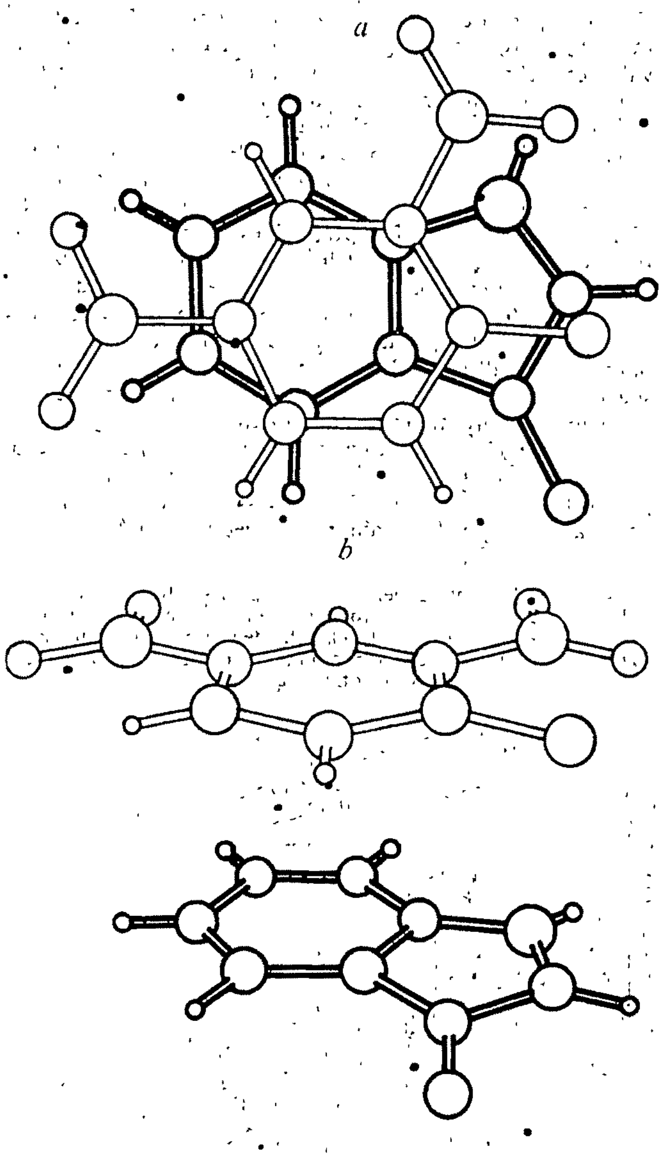


Fig. 3 The structure of the DNP-aspartate and tryptophan complex as deduced from ring current interactions. The two views are obtained from a computer search of the possible structures, with a separation between the two rings of 0.33 nm, which give calculated ring current shift ratios in best agreement with the experimental values. The shifts are calculated using the Johnson–Bovey equation modified to take into account the indole ring. The two views represent (*a*) a vertical view down the *z* axis and (*b*) the vertical view rotated 30° about the *z* axis and 60° about the *x* axis.

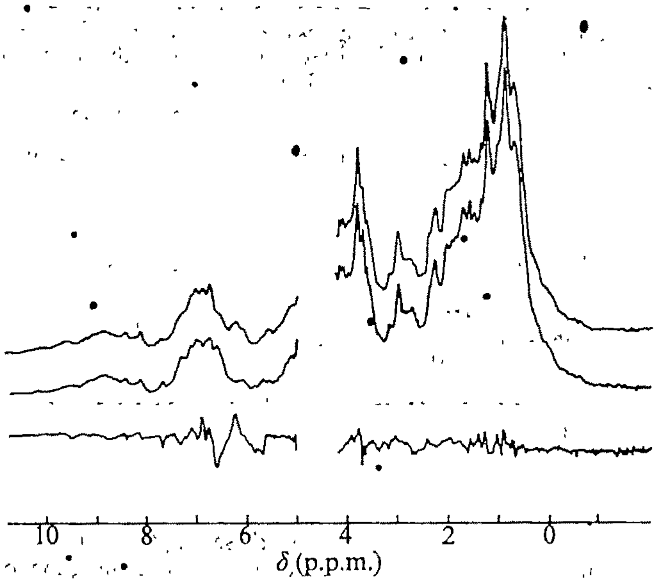

Fig. 4 The 270 MHz proton spectra of the Fv fragment alone and in the presence of Dnp aspartate and the difference spectrum between the two (enlarged × 4). Conditions were (Fv) = (Dnp-aspartate) = 1.15 mM, $pH = 6.9$, $T = 303$ K (0.15 M NaCl).

Table 2 Chemical shifts (δ_0) and the change in chemical shift ($\Delta\delta$) of resonances perturbed on binding of DNP-aspartate to the Fv from MOPC 315 at pH 6.9.

Hapten resonances	δ_0 (p.p.m.)	*$\Delta\delta$ (p.p.m.)	No. of protons

* Positive sign is downfield, negative sign is upfield shift change.

Measurements are made at 270 MHz, at $T = 303$ K and in the presence of 0.15 M NaCl. Shifts were measured from the sodium salt of 3-(trimethyl-silyl-propane) sulphonic acid, as an external standard.

geometries of a stacking arrangement of two rings. A closest distance of approach of the two rings of 0.33 nm is assumed since this is the distance found in a crystalline indole–TNP complex[20]. To avoid any problems from alterations in the strength of the ring current interactions from possible charge transfer and other effects the computer search uses the shift ratios. These ratios are then calculated for the protons in the complex in each geometry and these are tested against the experimental values. Two views of the structure of the complex as obtained from computer fitting are shown in Fig. 3. If this interaction occurs in the Fv–DNP-aspartate complex it would be expected that the n.m.r. spectrum of the complex should reveal upfield chemical shifts of similar magnitudes (that is 0.1–0.6 p.p.m.) for the DNP protons and of protons from the Trp residue in the Fv fragment.

The addition of varying amounts of DNP-aspartate to the Fv results in changes in the chemical shifts of the proton resonances at 270 MHz from both hapten and protein. The initial and final spectra are shown in Fig. 4, together with the difference spectrum between Fv and the 1:1 complex. If the histidine resonances are used as internal area markers only about 10 aromatic protons are perturbed on hapten binding. By means of difference spectroscopy the titration behaviour of all these resonances can be followed and the results are given in Table 2. On the protein, apart from the resonances assigned to a histidine (97$_L$, $pK_a = 5.9$) five protons have their resonances shifted upfield. The magnitude of these shifts are very similar to the DNP-induced ring current shifts of the tryptophan protons in the model complex. It seems reasonable to conclude that some, if not all, of the resonances in the protein which

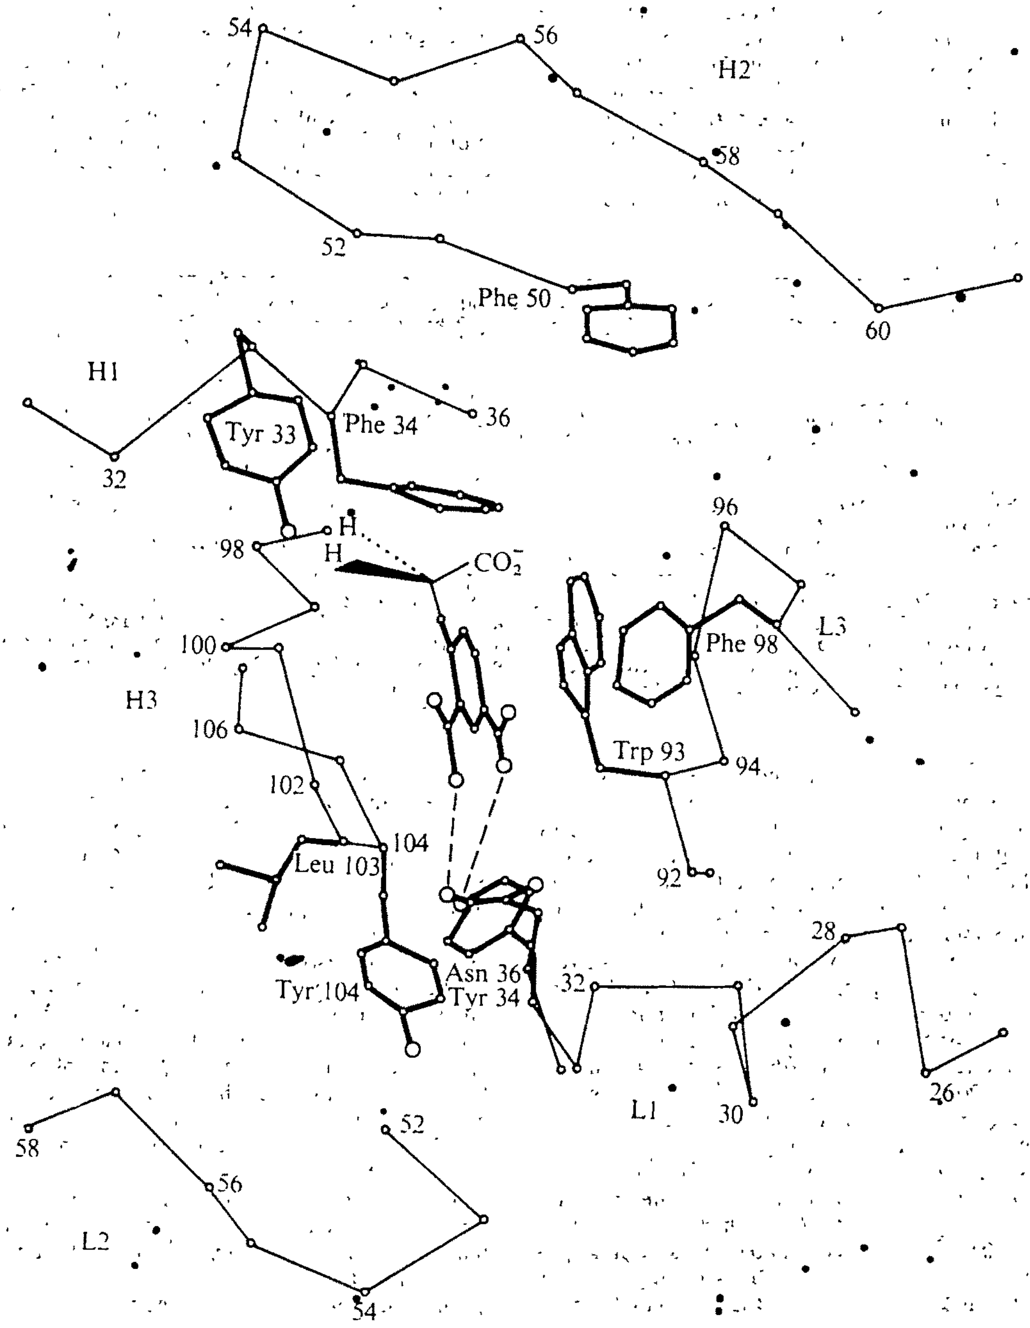

Fig. 5 The refined combining site of MOPC 315 based on the data in this paper. The positioning of Phe 34$_H$, Tyr 34$_L$, Trp 93$_L$ and Tyr 33$_H$ are obtained from ring current calculations. Tyr 104$_H$ can interact with Tyr 34$_L$. Some of the second layer of aromatic residues are shown. The orientations of the hapten is such that the two $-NO_2$ groups can form H bonds to Asn 36$_L$ and Tyr 34$_L$. Coordinates of this refined combining site are available on request.

are shifted upfield on addition of the hapten are from a tryptophan and that the DNP ring when bound in the Fv will interact with this tryptophan in a very similar manner to that shown in Fig. 3. Inspection of the proposed binding site in Fig. 1, immediately suggests that this tryptophan in the Fv is Trp 93$_L$.

The upfield shifts of the DNP protons when bound to the Fv are far larger than those in the DNP-aspartate–tryptophan complex. Analysis of these shifts reveals that it is necessary to invoke a minimum of two additional aromatic residues to explain the magnitude of these shifts One of these aromatic residues must be above and in almost van de Waal's contact with the H(5) and H(6) protons while a second aromatic residue is required to account for the shift on the H(3) proton. Reference to model suggests that these two residues are Phe 34$_H$ and Tyr 35$_L$. Hence the DNP ring is essentially enclosed in an 'aromatic box' consisting of Trp 93$_L$, Phe 34$_H$, and Tyr 34$_L$

The binding of DNP–glycine to the Fv provides the clue that now allows the orientation of the hapten in the site to be fixed. The side chain-CH_2-protons of this hapten experience a shift of 1 p.p.m. on binding to the Fv. To explain this shift it is necessary to introduce a fourth ring in the vicinity of the DNP situated about 0.3 nm above the CH_2 grouping of DNP–Gly. This can only be Tyr 33$_H$ which occupies similar position in the model. It is interesting that nitration of this tyrosine does not affect the binding constant of haptens to protein 315 suggesting that the interaction between Tyr 33$_H$ and the hapten is through the ring and not the hydroxyl. In contrast, in protein 603 an H bond is formed between Tyr 34$_H$ and the phosphate group of the phosphoryl choline hapten.

Consideration of geometry of DNP glycine then shows that the H(3) proton is on the opposite side of the molecule to the CH_2 Thus the H(3) proton must be over Tyr 34$_L$ while the H(5) and H(6) protons are in van de Waals' contact with Phe 34$_H$. Further refinement of the environment of Tyr 34$_L$ comes from the observation of an Overhauser effect[14] on the H(3) proton of the DNP ring: Irradiating the protein resonances in the Fv at 6.6 p.p.m. results in the reduction of the signal intensity of this H(3) proton. This implies that one or more protons on Tyr 34$_L$ (which have resonances at this position) are within 0.3 nm of the H(3) proton. Further the affected protons on Tyr34$_L$ must be influenced by another aromatic ring since the resonance at 6.6 p.p.m is shifted upfield by ~0 6 p.p.m. from the position expected for an unperturbed tyrosine residue. According to the predicted model this other aromatic ring can only be Tyr 104$_H$ but this necessitates repositioning this residue so as to be vicinal to Tyr 34$_L$. This is only possible if the position of Leu 103$_H$ is altered in the postulated model so as to point out of the site in which event Tyr 104$_H$ will point into it and can then interact with Tyr 34$_L$. This is also compatible with the lack of any large change in methyl resonance in Fv on hapten binding.

Other differences from the predicted model also arise from consideration of a 'second layer' of aromatic residues For instance the protons assigned to Trp 93$_L$ are themselves ring current shifted upfield from the normal expected positions in a protein. This suggests that Trp 93$_L$ points back into the site where the protons of the six-membered ring can be upfield-shifted by Phe 98$_L$ Finally the positioning of the hapten allows conclusions to be drawn about possible H-bonding schemes The two nitro groups on the hapten seem to be necessary for strong binding and suggest some H-binding interactions to amino acid side chains[3]. The only possible H-bonding groups which can interact with NO_2 groups on the DNP ring positioned as discussed above are Asn 36$_L$ and Tyr 34$_H$ Interestingly both these H bonds as well as the involvement of Trp 93$_L$ are on the light chain and may be the reason for a weak binding site on light chain[22] and the V_L dimer[23] for DNP ligands The refined model of the combining site modified according to the data in this paper is shown in Fig. 5 and illustrate the considerable agreement with the original model However, the n m.r. results allow very precise positioning of the contact residues and given the assumptions that aromatic rings are the only source of upfield shift interactions and that there is no motional averaging of these rings, the placing of the rings around the binding site is estimated to be accurate to ±0.05 nm.

Table 3 Comparison of combining site residues which interact with ligands*

* Interacting residues (italic) are according to refs 1 and 2 for New and 603 respectively and from this work for protein 315. When no residues are marked the possibility of interacting with peptide chain backbone is not excluded. H1, H2, H3, L1 and L2 are hypervariable regions of H and L chains. X, unknown residue due to incomplete sequence The numbering of sequences is according to protein 315 with homology maximised. We thank Professor R. J. Poljak for the revised sequence of protein New residues 31–35 before publication

† Changed from lysine after partial resequencing (D. Givol, personal communication).

Several interesting points emerge from the comparison of the combining site of protein 315 with those of protein New and 603. In Fab' New-vitamin K_1OH complex, the naphthoquinone ring of vitamin K_1OH is in close contact with Tyr 90$_L$[1] (Tyr 93$_L$ in Table 3) Sequence homology shows that Trp 93$_L$ in protein 315 which interacts with the DNP is homologous to Tyr 90$_L$ in New, and therefore this provides an interesting example for a change in specificity on replacing one residue in the site. Note that protein 315 also binds menadione in lower affinity than DNP (ref 24), but protein New does not bind DNP ligands. Charge interactions play a dominant part in the binding of protein 603 to the hapten phosphoryl choline[2] On the other hand, another model building study on rabbit anti-type III polysaccharide (BS-5) suggest clustering of the hydroxyamino acids Tyr, Ser and Thr and also Asn in the combining site which can form H bonds with hydroxyls of the sugar ligand[25]. It is clearly seen that some pattern of changes in the antibody binding site can be deduced from such comparative studies as illustrated in Table 3.

The magnetic resonance study of interaction between haptens and antibody provides a functional sense to the structure predicted by model building. It is possible to assign interactions to residues in the site and also to determine their correct orientation with respect to the hapten. The positioning of Trp 93_L, Phe 94_H, Tyr 34_L, Asn 36_L, Arg 95_L and other residues allows understanding of the specificity of binding DNP ligands to protein 315 and indicates that this approach when applied to other antibodies will provide information about the structural basis of antibody specificity.

The continuous help, advice and many suggestions made by Professor R. R. Porter are gratefully acknowledged. We also thank Professors R. J. P. Williams and D. C. Phillips for stimulating discussions, and Miss E. M. Press, Mrs C. Wright, C. Sunderland and Drs D. Marsh, R. Jones, A. C. McLaughlin, N. C. Price and A. I. White and K. Willan, for their help in the early stages of this work. We are also grateful to Dr Iain D. Campbell for help with the n.m.r. studies.

Acceleration of charged particles to extremely high energies in pulsar far fields

SINCE the inception[1] of the pulsar magnetosphere, it has been realised that charged particles, streaming away from the neutron star beyond the light cylinder, would attain high energies. Goldreich and Julian[1] calculated the potential drop Φ_M across the open field lines at the polar cap of the star, noting that this was the order of the maximum energy that such particles could attain. Φ_M is of order 10^{16} V for the Crab pulsar. They estimated (their equation (34)), however, that the energy actually reached would be very much less than this. I show here that in fact all escaping particles will reach energies of order Φ_M.

We assume that the electromagnetic field is given adequately by the force-free approximation[2,3], in which particle mass is neglected, and then calculate the motion of charges in this field to first order in the mass. This leads to an estimate of the region of adequacy of the approximation.

If the mass is neglected altogether, the motion is simply

$$\mathbf{v} = \mathbf{U}_E + v_{\parallel}\mathbf{B}/B \tag{1}$$

where $v_{\parallel}$, the component along the magnetic field $\mathbf{B}$, is unrestricted. In force-free theory[4], the electric field, E, is given by

$$\mathbf{E} = -\mathbf{v}_R \times \mathbf{B} \tag{2}$$

where $\mathbf{v}_R$ is the co-rotation velocity $\Omega \times \mathbf{r}$, Ω being the angular velocity of the star. Thus the electric drift $\mathbf{U}_E$ is

$$\mathbf{U}_E = \mathbf{E}\times\mathbf{B}/B^2 = \mathbf{v}_R - (\mathbf{v}_R\cdot\mathbf{B})\mathbf{B}/B^2 \tag{3}$$

At large radial distances, $\mathbf{U}_E$ becomes radial[5-7], and equal to c (within the force-free approximation). In the general, non-axisymmetric case[7], the far field is dominated by an electromagnetic wave (of frequency Ω), for which $E/B = c$, so this result is clear.

It is essential within the approximation that $\mathbf{U}_E$ should not exceed c. The Lorentz factor γ_E corresponding to $\mathbf{U}_E$ follows from (3):

$$\gamma_E^2 = B^2/\mathbf{B}\cdot\widetilde{\mathbf{B}} \tag{4}$$

where

$$\widetilde{\mathbf{B}} = (1 - v_R^2/c^2)\mathbf{B}_p + \mathbf{B}_t \tag{5}$$

The derived field $\widetilde{\mathbf{B}}$ is of fundamental importance in force-free theory[2,3]. We require therefore for the validity of the approximation, that

$$\mathbf{B}\cdot\widetilde{\mathbf{B}} \geqslant 0 \tag{6}$$

It follows from the universal spiral structure of the far field[7] that whereas B^2 decreases as r^{-2}, $\mathbf{B}\cdot\mathbf{B}$ decreases as r^{-4}. There is a great degree of arbitrariness at present in the directional dependences of the quantities, but we assume that there exists a class of solution for which (6) is valid. At large r therefore,

$$\gamma_E \simeq F r/r_l \tag{7}$$

where r_l is the light radius c/Ω, and F is some function of direction.

To zero order in the mass therefore, the particles gain energy in proportion to their distances from the star. To find out when inertial forces will curb this process, we must calculate the first order 'guiding centre drift'. This depends partly on $v_{\parallel}$, calculation of which in general[8] necessitates integration of an equation for $dv_{\parallel}/dt$. Here, this is unnecessary because of the existence of an exact integral of the motion due to Endean[9],

$$\mathcal{E} = \gamma(1 - \mathbf{v}_R\cdot\mathbf{v}/c^2) \tag{8}$$

This arises from the requirement that the whole system be stationary in the co-rotating reference frame. When $\mathbf{v}$ is inserted from (1) into (8), there results a quadratic equation for $v_{\parallel}$ whose coefficients depend on $\mathbf{B}$ and $\mathcal{E}$. For values of r sufficiently large that (7) is adequate, the physical root of this equation, and the associated value of γ are approximately followed by equation (9):

$$v_{\parallel}/c \simeq -(\sigma\, \mathscr{E}/(\sin\theta F))\,(r_l/r)^2, \qquad \gamma \simeq \gamma_E, \tag{9}$$

where θ is the polar angle, and σ is the sign of B_t.

The calculation of the drift is (apart from straightforward relativistic extensions) standard[10]. We assume that any gyromotion is lost by synchrotron radiation near the light cylinder. Drifts involving $v_{\parallel}$ turn out to be negligible because of its r^{-2} dependence. (Thus the motion is eventually independent of initial conditions which appear through $\mathscr{E}$.) The dominant drift is

$$v_{\perp} = \frac{m}{q}\left\{\mathbf{B}\times \mathrm{d}(\gamma \mathbf{U}_E)/\mathrm{d}t\right\}\Big/B^2 \tag{10}$$

evaluated along the zero order trajectory. The corresponding corrected γ reduces eventually to

$$\gamma \simeq F(r/r_l) + \delta G(r/r_l)^2 \tag{11}$$

where G is a second function of direction obtainable from a given force-free model, and δ is the small number

$$\delta = \Omega/\omega_{BL} \tag{12}$$

where ω_{BL} is a measure of the non-relativistic gyro-frequency at the light radius. For the Crab pulsar δ is of order 10^{-11} for electrons and 10^{-8} for protons.

The drift approximation will fail when the two terms in (11) are comparable. We can only speculate on what occurs beyond this but it seems likely that gyro-motion will appear[1], and that there will be no further energisation. We assume that this is the case. In a given direction there will be a maximum value γ_M, and corresponding energy K_M, at a distance r_M where

$$\begin{aligned} r_M &= R\, r_l/\delta, \\ K_M/mc^2 &= \gamma_M = \Gamma/\delta, \end{aligned} \tag{13}$$

where, roughly, $R \approx F/|G|$ and $\Gamma \approx 2F^2/|G|$. We assume that the field falls as r^{-3} from the star to the light radius, thence as r^{-1}. If the stellar radius and field strength are $R_s \times 10\ K_M$, and $B_s \times 10^8$ T, respectively, then

$$\begin{aligned} r_M/R = e\Omega R_s^3 B_s/mc^2 &= 6\times10^{-3}\ \Omega R_s^3 B_s \text{ pc (electrons)} \\ &= 3\times10^{-6}\ \Omega R_s^3 B_s \text{ pc (protons)} \\ K_M/\Gamma = e\Omega^2 R_s^3 B_s/c &= 4\times10^{11}\ \Omega^2 R_s^3 B_s \text{ V} \end{aligned} \tag{14}$$

K_M has the same order as the Φ_M of Goldreich and Julian[1], and is about 2×10^{16} V for the Crab pulsar. The field at r_M is such that the non-relativistic gyro-frequency is comparable with Ω. This is of course expected where the drift approximation breaks down It is much larger than any possible interstellar field for protons, but for slower pulsar periods of order 1 s, it is of order 10^{-10} T for electrons. Electrons therefore, may be lost from the system before attaining their maximum energy. The distance r_M would seem to be well within the surrounding nebula of any pulsar.

A rough estimate of the flux of energy from the system carried by the particles yields a figure comparable to the dipole radiation rate. Again then, it is clear that the approximations break down at r_M, and that a self-consistent approach must replace the force-free approximation at such distances.

Finally, the loss of energy ΔK due to radiation reaction during the motion is negligible. This is basically because particles are travelling at the speed of light in straight lines. Using standard formulae[11] it is readily shown that the ratio $\Delta K/K_M$ is of order Ωt_r, where t_r is the classical radiation time scale 10^{-23} s (electrons). Thus ΔK is completely negligible.

Further details of the process, and the breakdown of the force-free approximation will appear elsewhere.

Redshift effect on the timescale of quasar radio variability

It has been suggested (ref. 1 and McCrea (I.A.U. Symposium No. 63, 1972)) that the radio or optical variability of quasars should be related to their redshifts. If the latter originate from the Doppler effect, or are gravitational, the observed fluctuation rate of the radio or optical emission should also be redshifted, that is, slowed down, in proportion to $1+z$, where z is the usual redshift factor. Medd *et al.*, measuring quasar flux densities with the Algonquin telescope, attempted to detect this effect by plotting the frequency of maxima occurrence in the flux-density curves against z but obtained an inconclusive result. Scargle[2] also analysed the Algonquin observations, using the half-width of the autocorrelation function of the flux-density curve as a measure of fluctuation rate. Again, the results show considerable dispersion, but Scargle argues that regression analysis supports the expected relationship. We present here a preliminary version of an analysis based on the power spectrum of the flux-density curves, which establishes the expected result.

Our analysis was restricted to the λ2.8 cm measurements (ref. 1 and B. H. Andrew and G. A. Harvey, personal communication) of the 33 identified quasars in the Algonquin sample for which redshifts were available. The data covered periods of 74–110 months between 1966.5 and 1975.7, a month being defined as 1/12 yr. The record lengths are variable, therefore; moreover, they contain gaps and the observations are not equally spaced in time.

The data were interpolated to produce equally-spaced samples at 1-month intervals by a weighted linear interpolation (convolution); the convolving function was triangular, with a base of 6 months. (This has a significant filtering effect on the power spectrum which was subsequently corrected.) Where the gaps were too wide to use this function, the data were interpolated linearly The d.c. component of the record, and any linear trend, were removed by fitting a straight line in a least-mean-squares sense A cosine taper was applied to 10% of the record length at each end, and all records were converted to a uniform length of 128 months by adding zeros at the end. The resulting records are 128 samples long, appropriate for applying the Fast Fourier Transform. The transformation results in spectra which are tabulated at intervals of 1/128 = 0.00781 cycle per month. The spectral amplitudes were then squared to arrive at the power spectra of the flux-density curves.

A typical spectrum is shown in Fig 1*a*. At frequencies < 0.01 cycle per month, a finite record length coupled with the absence of d.c. power biasses the first three points downwards. At high frequencies the spectrum consists only of noise, representing the original measurement errors in the flux densities Between these extremes is a regime where ln$P$ falls approximately linearly with frequency, shown more clearly in Fig. 1*b* All 33 quasars have a similar form of spectrum, though noise makes the similarity less clear-cut for those which vary weakly in comparison with the flux measurement errors. Attention was therefore restricted to those 13 quasars for which the s.d. of the time-series record exceeded that of the quoted measurement errors[1] by a factor of 1.7, which corresponds to a convenient break in the distribution of s.d. ratios.

If the variability spectrum of a given quasar could be measured for a redshift $z = 0$ then at a finite redshift z, the effect on the spectrum would be to steepen the slope $\mathrm{d}(\ln P)/\mathrm{d}f$ by the factor $1+z$. A plot of slope against $1+z$ for different quasars might also be expected to show this relationship, provided the dispersion in variability rate from one quasar to another is not so strong as to obscure it.

For each quasar, the slope was measured by computing the average values P_1 and P_2 of P over the frequency ranges 0.0117–0.0508, and 0.0508–0.0898 cycles per month, and forming the quantity $(\ln P_1 - \ln P_2)/0.0391$. The averaging ranges were chosen as a compromise between a wide range, which would give a good estimate of the slope, and the necessity to restrict the measurement to that part of the spectrum having a high signal-to-noise ratio. The results are plotted in Fig. 2. There is clearly evidence for a correlation in the expected sense.

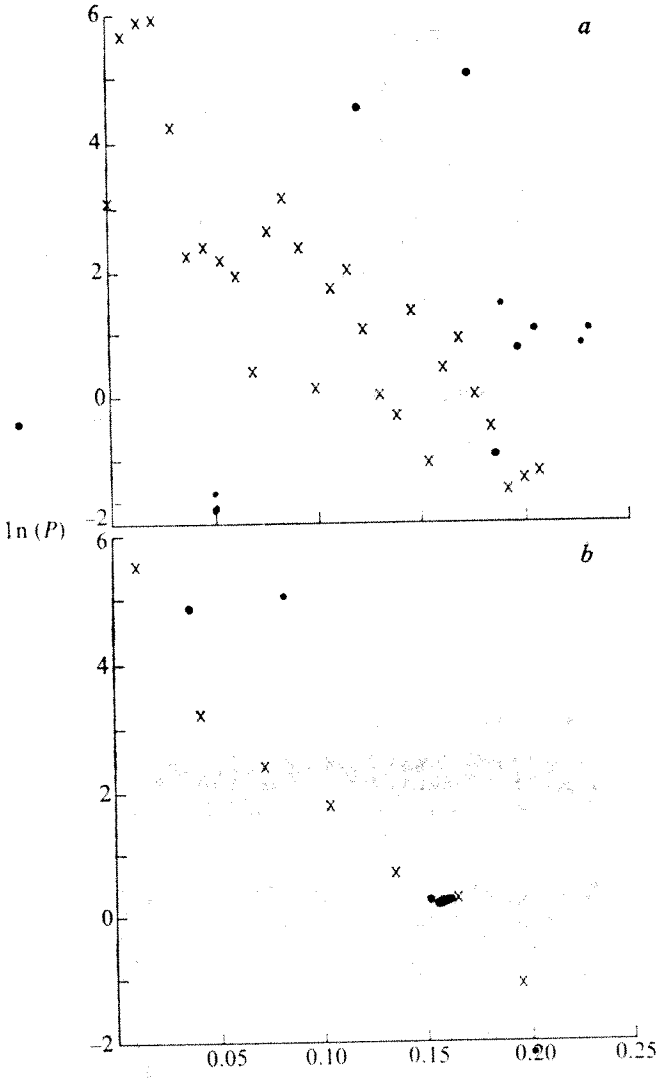

Fig. 1 Power spectra of the radio flux variations of CTA 26, corrected for the filtering effects of the convolving function. The ordinates are the natural logarithms of the power spectral density P, in units of Jy^2 (cycles per month)$^{-1}$. a, raw spectrum at a resolution of 0.0078 cycles per month. b, spectrum smoothed by averaging in groups of four points.

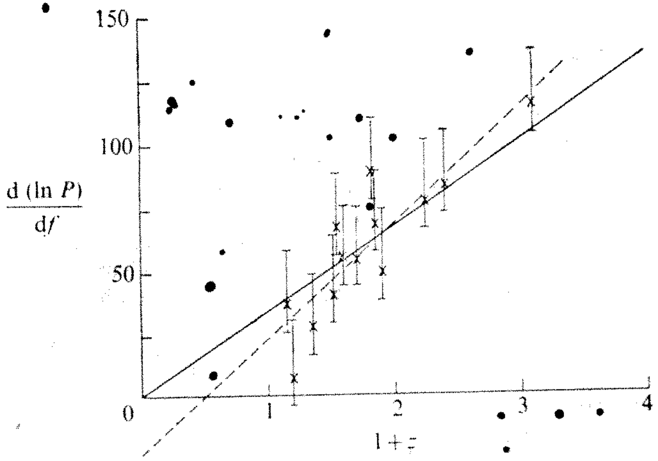

Fig. 2 Plot of $\mathrm{d}(\ln P)/\mathrm{d}f$ against $(1+z)$. The full line is a regression of y on x which is constrained to pass through the origin. The dashed line is not so constrained. The 1σ confidence bars are derived from the χ^2 distribution of the spectral estimates.

Assuming that the time-series are random and not deterministic, and that they are noise-free, spectral estimates will follow a χ^2 distribution. Since the data were selected to have a high signal-to-noise ratio, this will be very nearly correct. Confidence limits of 1σ have been computed (Fig. 2). The assumption of randomness is crudely verified *post facto* as the χ^2 estimates seem to be consistent with the observed scatter in the spectra.

Figure 2 shows a correlation in the expected sense between the spectral slope and the redshift, and the value of the correlation coefficient is computed to be 0.88. It is, however, difficult to set a proper confidence limit on this result, because the usual tests are based on a normal distribution of errors in the data, which is not the case here. Nevertheless, we have assumed normality, to set a rough confidence limit on the result, an assumption which finds crude justification in the central limit theorem[3]. The correlation coefficient is then significant at a level much lower than 1%.

Although the correlation is significant, the expected proportionality between spectral slope and $(1+z)$ should cause the regression line to pass close to the origin. In fact, its intercept on the y-axis is -26.6, but the significance of this departure is only 7% (again assuming normality) so the fact that the regression line does not pass through the origin is not very significant. The regression of y on x with the line constrained to go through the origin is shown in Fig. 2.

Our establishment of the expected correlation between the observed rate of radio variability and redshift implies that whatever causes the redshift of the optical spectral lines must also slow down the observed variability rate. Because the unshifted variability rate is not known *a priori* (unlike the frequency of optical spectral lines), we cannot establish that the radio variability is subject to the same value of $(1+z)$. Our data would be consistent, for instance, with an interpretation in which the radio emission were subject to exactly half the optical value of $(1+z)$. If the redshift is supposed to have a Doppler (or a gravitational) origin, our data require that the optical and radio emission arise in regions with equal or related recessional velocities (or gravitational potentials).

An interesting inference from Fig. 2 is that the intrinsic spread of quasar variability rate (at a given redshift) is low, at most of the order of 3, and presumably lower if the effects of the χ^2 variance were reduced, by accumulating longer records. This suggests that variability rate may be a useful parameter for cosmological investigations, assuming the redshift is cosmological, and could be used, for instance, to measure redshift as a function of cosmological epoch.

The exponential power-spectrum of quasar variability can be useful in considering the astrophysics of these objects. If the form of the spectrum is $P = Ae^{-kf}$, then the mean value of can be deduced from Fig. 2 using the value of the ordinate of the full regression line for $z = 0$. We obtain $k = 33.3$ (cycles per month)$^{-1}$, implying that most of the variations take place at frequencies $< k^{-1} = 0.03$ cycle per month.

Further work clearly depends on acquiring more data, and on minimising the effects of errors on the present data. The number of points in Fig. 2 could be more than doubled if the 20 weakly-variable quasars in our original sample could be used.

We acknowledge the cooperation of Mrs Gladys Harvey, Dr B. Andrew and Dr J. MacLeod of the Canadian National Research Council in making their recent data available.

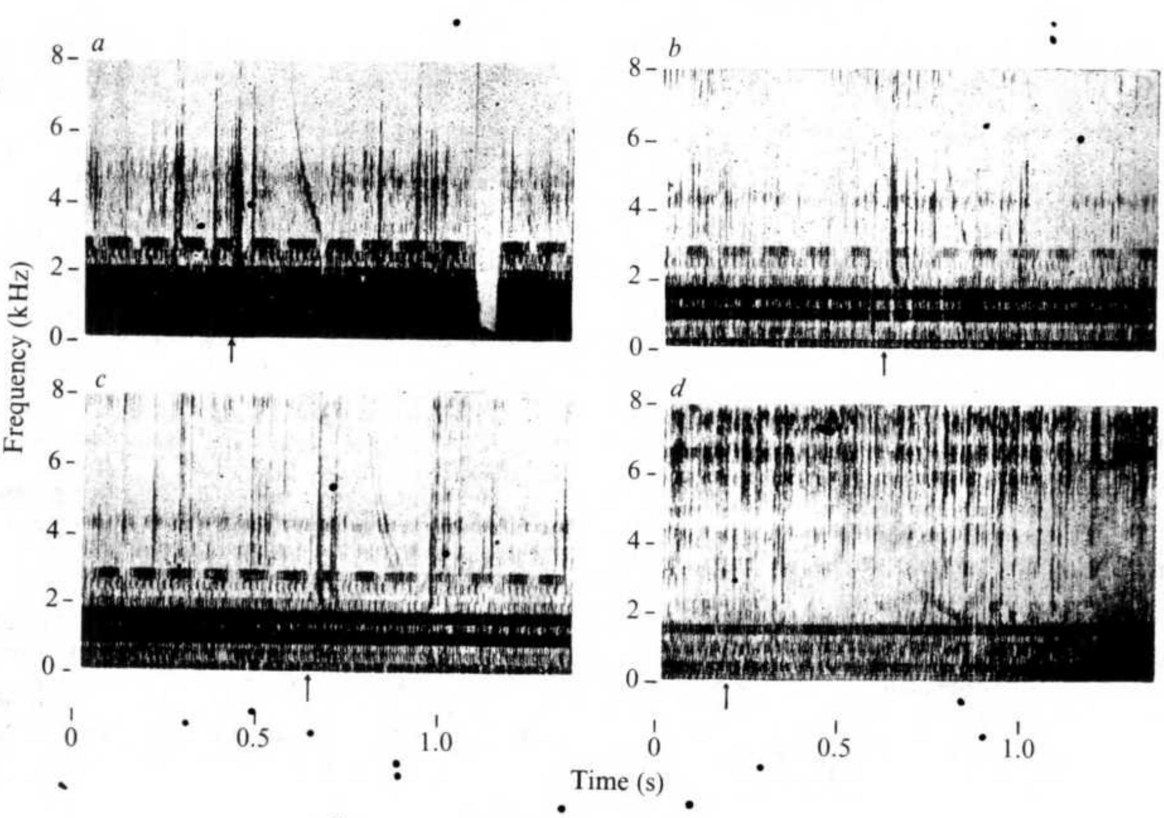
Whistlers recorded at Varanasi

THE study of low-latitude whistlers dates back to the pioneering work of Japanese scientists. The whistlers were first recorded at Toyokawa (geomag. lat., 24.5°N)[1], and later efforts were made to record them at lower latitudes. The first successful records of whistlers in India were obtained at Gulmarg (geomag. lat., 24°10′N) by Somayajulu *et al.*[2]. Recording was later carried out at Nainital (geomag. lat., 19°1′N) and whistlers with comparatively lower dispersion and reduced rate of occurrence were reported[3–5]. Unsuccessful efforts were also made to record whistlers at Varanasi (geomag. lat., 15°6′N). Analysis of the low latitude whistler records by Rao *et al.*[6] showed that the low-latitude whistler cut-off lies around 15° latitude, and apparently provided the reason for the non-recording of whistlers at Varanasi. Using an improved system, we have succeeded in recording whistler activity at Varanasi, and we describe here the categories of sonograms recorded in April, 1976.

It is well known that the global thunderstrom activity is at a maximum at the temperate latitude and decreases with increasing latitudes[7]. The parameters or mechanisms controlling the guidance of thunderstorm-generated low-frequency waves are less effective at low latitude, however, which seems to reduce the occurrence of whistler activity. The combination of these two controlling factors maximises the rate of occurrence around 50° geomagnetic latitude and results into a low-latitude whistler rate cut-off. It is obvious that the sporadic redistribution of thunderstrom activity and so-called enhancement factor controlling the guidance of whistlers at times changes the latitude of maximum occurrence rate of whistlers and shifts the low-latitude cutoff to still lower latitudes.

The interpretation of such a low-latitude cutoff seemed artificial and efforts to record whistlers at Varanasi continued, using an improved antenna system and preamplifier. The recorded sonograms (Fig. 1) show much noise with very distinct causative atmospherics. The whistler activity at Varanasi showed highest occurrence rate during the months of February–April, 1976, and generally occurred in the post-midnight hours. They can be classified into four different categories. Figure 1*a* shows a single trace short whistler with distinct causative atmospherics; the dispersion is 12 s$^{1/2}$. Figure 1*b* shows a feeble trace of banded whistler with almost similar dispersion features. The bands at lower frequencies are very clear, but are not distinct at higher frequencies. Figure 1*c* depicts two causative atmospherics

Fig. 1 Sonogram of whistlers recorded at Varanasi. *a*, 0026, 7 April 1976, short whistler; *b*, 0106, 4 April 1976, banded whistler; *c*, 0039, 7 April 1976, twin whistler; *d*, 2242, 4 April 1976, whistler with high dispersion. A model UHER 4400 Report stereo tape recorder provided the continuously recorded sonograms.



and gives an initial impression of multiflash, but dispersion analysis showed this to be a short twin whistler. Multiflash whistlers have not yet been recorded at this station. The dispersion feature is almost similar to that shown in Figs 1*a* and *b*. A curious but frequent trace is shown in Fig. 1*d*, where only a part of the trace in the low-frequency region (2–4 kHz) is seen and the high-frequency part of the trace does not appear. The extrapolation of the trace and the location of causative atmospherics shows a comparatively large dispersion of 25 $s^{1/2}$. The non-appearance of high-frequency part in this sonogram associated with this higher dispersion is capable of revealing certain additional features of low-latitude propagation path. To our knowledge such records have not been reported either at high- or low-latitude stations. The non-appearance of the trace at frequencies higher than 4 kHz is related, either to the enhanced absorption or to poor guidance of whistlers. Examination of the sonograms shows that such traces are often seen before or after the formation of banded whistlers (Fig 1*b* and *d*). It therefore seems less probable that the enhanced average absorption of the propagation path is a likely cause of absence of high-frequency trace of the sonogram. At the first glance the absence of high-frequency trace can be visualised as a particular case of banded whistlers which are believed to be some manifestation of shape, size and movement of ionospheric irregularities[8]. A detailed dispersion analysis of these sonograms is now being carried out to study various ionospheric and magnetospheric features.

Argon degassing models of Mars

ON July 20, 1976 Viking I lander made a soft landing on the martian surface. Atmospheric pressure recorded on the surface by the lander was 7.7 mbar and main constituents of the atmosphere were 95% CO_2, 2–3% N_2, 1–2% Ar and 0.3–0.4% O_2 (ref. 1). The (^{40}Ar/^{36}Ar) isotopic ratio was 2,750 ± 500 as measured by a mass spectrometer[1]. This high isotopic ratio suggests an unique history for the evolution of the martian atmosphere. The possible mechanisms of argon degassing models of Mars are discussed here.

Since the decay of radioactive ^{40}K produces ^{40}Ar, the time variation of (^{40}Ar/^{36}Ar) isotopic ratio in a closed system can be determined by two initial ratios, (^{40}Ar/^{36}Ar)$_0$ and (^{36}Ar/K)$_0$. For the present case (^{40}Ar/^{36}Ar)$_0$ at the time of the planetary formation is considered to be very small ($\sim 10^{-4}$) from the theory of nucleosynthesis[2]. Hence the initial (^{36}Ar/K) ratio uniquely determines the later (^{40}Ar/^{36}Ar) ratio within the planet. The time variation of the isotopic ratio (^{40}Ar/^{36}Ar) as a function of the initial (^{36}Ar/K)$_0$ ratio is shown in Fig. 1. Observed (^{40}Ar/^{36}Ar) ratios in the terrestrial and the martian atmosphere are indicated by the arrows in the figure.

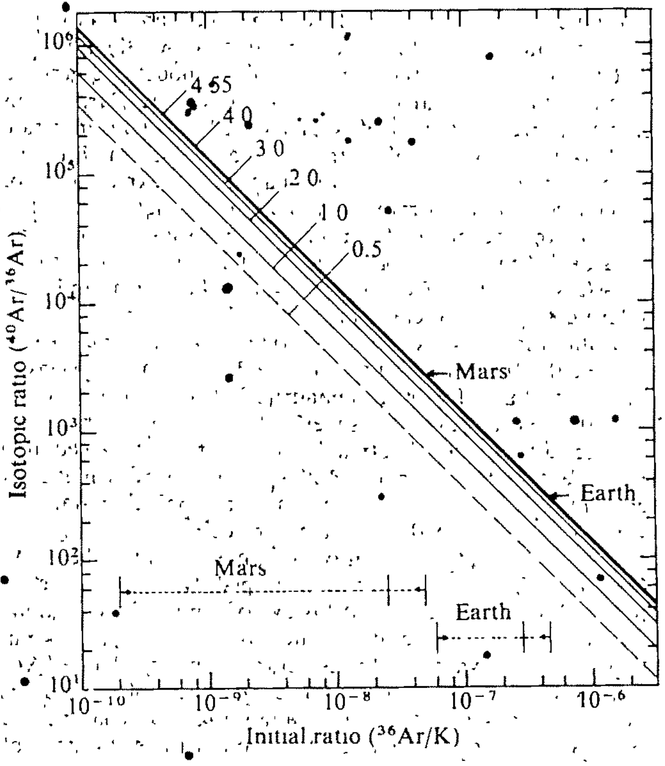

Fig. 1 Time variation of (^{40}Ar/^{36}Ar) isotopic ratio in a closed system as a function of initial (^{36}Ar/K) ratio. Two arrows indicate the isotopic ratios in terrestrial and martian atmospheres. Estimated ranges of the initial (^{36}Ar/K) ratio for Earth and Mars are shown in the lower part.

The present isotopic ratio (^{40}Ar/^{36}Ar) in the atmosphere depends on the degassing history of Ar from the planetary interior, so these observed atmospheric values can not determine the initial (^{36}Ar/K)$_0$ ratio. The possible range of the ratio, however, can be inferred from the observed isotopic ratio. If we assume the atmospheric Ar is degassed fraction from the planetary interior, the (^{40}Ar/^{36}Ar) ratio in the interior should be greater than the atmospheric value. This gives a maximum estimate for the initial (^{36}Ar/K)$_0$ ratio. For the Earth this value is about 4.5×10^{-7}. For the minimum estimate of (^{36}Ar/K)$_0$, we can assume ^{36}Ar has completely degassed to the atmosphere. This gives a value of 6×10^{-8} for the Earth with a chondritic mantle. The same argument suggests a possible range, $2 \times 10^{-10} <$ (^{36}Ar/K)$_0$ $< 4.5 \times 10^{-8}$, for Mars. These estimated possible ranges are shown in the lower part of Fig. 1.

Assumptions on the degassing model of Ar are needed to narrow the range. Turekian[3], assuming a first-order rate process for Ar degassing, obtained the degassing rate constant from the abundance of ^{40}Ar in the terrestrial atmosphere. Using his result and the atmospheric ^{36}Ar abundance, the initial (^{36}Ar/K)$_0$ ratio is estimated to be about 3×10^{-7}. Although he assumed a chondritic Earth (K content 880 p.p.m.), the initial ratio is almost independent of the assumption of K content in the Earth. Ozima[4] concluded initial catastrophic and later continuous Ar degassing model from the suggested high (^{40}Ar/^{36}Ar) ratio (more than 2,000) in the present mantle. This model requires a smaller (^{36}Ar/K) ratio than the continuous degassing model. The continuous degassing model for the martian atmosphere gives a value of 3×10^{-8} for the initial (^{36}Ar/K) ratio

This analysis of the Ar degassing model suggests a smaller (^{36}Ar/K)$_0$ ratio for Mars than for the Earth. This implies a higher content of K and/or a lower concentration of ^{36}Ar in the whole of Mars than in the Earth. Physical adsorption is the only known quantitative explanation of planetary primordial rare gas in chondritic meteorites[5] The size of the adsorbed fraction is very sensitive to temperature condition and increases as temperature decreases. As Mars is further from the Sun than the Earth, and considering the pre-planetary history of the solar nebula[6], it is probable that Mars is at least as rich in original volatiles as the Earth It seems likely that the K content of Mars is similar to that of normal chondrites[7] (900 p p.m.). Even if we assume that the atmospheric Ar on Mars consists of very recent degassed fraction from the interior, the required K content of Mars is about 1,200 p.p m An even higher K content is necessary to explain the apparent stational volcanic activity on the martian surface[8].

To overcome this difficulty, we must assume that ^{36}Ar (and probably other volatiles) escaped from the martian region during the geological history of Mars This escaping mechanism should operate in the early stage of the evolution of Mars, where (^{36}Ar) is more abundant than (^{40}Ar) The explanation of the chemical composition of the planets by the condensation theory[6], requires that the solar nebula escapes from the inner planetary region at the early stage of the solar evolution This process may contribute to remove the initially degassed volatiles from Mars Although the above discussion is based on the atmospheric content of Ar, the degassing history of volatiles closely related to the differentiation process in the planet, which can be inferred from petrological investigations of surface rocks as studied for the Moon[9]

If such investigation reveals an early large-scale differentiation of Mars, the above conclusion would be confirmed I thank Professor M Ozima for valuable discussions and encouragement

Conductivity dispersion in single-crystal β-alumina electrolyte

WE report data which demonstrate the existence of a conductivity dispersion in single-crystal β-alumina and, we believe, for the first time, a distribution of conductivity relaxation times in any single-crystal ionic conductor A cylindrical boule of high quality Na β-alumina grown at Union Carbide was supplied to us by Roditi International Corporation. Figure 1 shows the frequency-dependent conductivity of this crystal in the range 10^2–10^7 Hz, measured at various subambient temperatures (for details of the apparatus see refs 1 and 2) At normal temperatures, electrode effects produce an apparent dispersion in conductivity At these lower temperatures, however, the dispersion seems to be an intrinsic property of the bulk material since it starts at frequencies which are related to the level of the d c. conductivity ($f \approx \sigma/2\pi\epsilon$)[1,2] as indicated by arrows in (Fig 1) This behaviour closely resembles the dielectric behaviour which has been studied in silicate and other glasses[3,4]. The dispersions in conductivity cannot be accounted for in terms of the conventional (Debye) theories of dielectric loss, indeed, the departures from Debye behaviour are probably more marked in single-crystal β-alumina than in many vitreous electrolytes

This result can be interpreted in terms of a broad distribution of conductivity relaxation times, which could plausibly be related to the random distribution of sodium ions over distinct crystallographic sites within the conduction planes (as revealed for example by recent X-ray and neutron diffraction studies)[5,6] These studies have shown that at ≲90 K, sodium ions are localised at three distinct sites, but with increasing temperature there is increasing cation mobility, and by 620 K the disorder resembles that of a two-dimensional fluid. The details of this picture have been confirmed by NMR spectroscopy[7], but of special relevance to this discussion, it should be noted that the existence of a 'wide distribution in ion jump frequencies' was postulated[5] to account for certain aspects of the data The conductance dispersion which we have observed would then follow directly from a model involving sequential hopping of ions over the different crystallographic sites

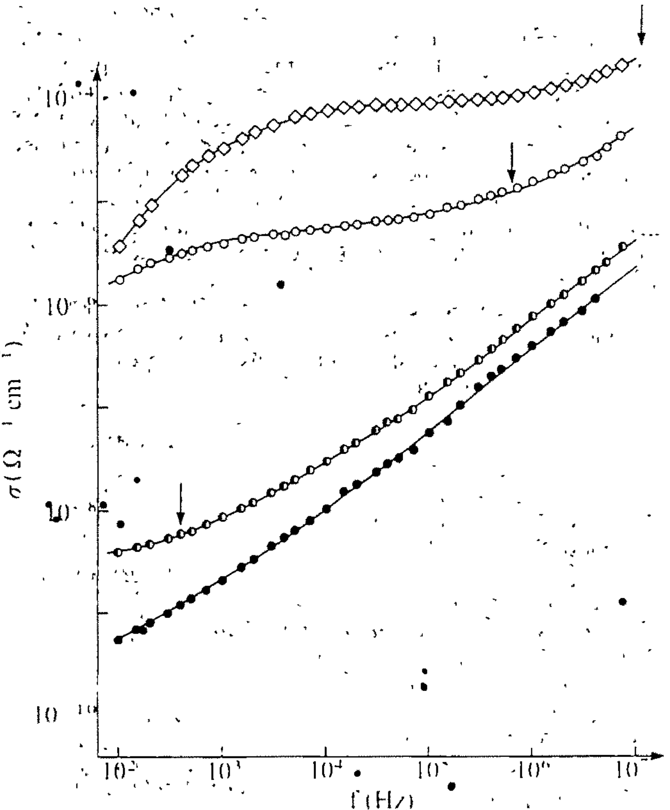

Fig. 1 Frequency-dependent conductivity of single-crystal β-alumina at 77 K (●), 87 K ( ), 113 K ( ) and 143 K (◇)

It is also possible, however, to place a different interpretation on these data In Fig 1, it is apparent that at low temperatures, the high-frequency or a c. conductivities fit a 'universal law' which has been described by Jonscher[8–10]. In the region of conductance dispersion, the a c conductance $\sigma(\omega)$ is given by:

$$\sigma(\omega) = A\omega^n \tag{1}$$

where n = 0·78 at 87 K, and is somewhat insensitive to changes in temperature. This 'law' is obeyed by a wide range of materials, and an interpretation has been given by Jonscher in terms of a 'screened' charge model where the ratio of energy stored to energy lost per cycle is independent of frequency On the basis of this theory the conductivity dispersion in β-alumina need not be related to a microscopic distribution of ionic jump frequencies, but could be understood in terms of an interionic 'drag effect' which gradually relaxes with increase in frequency. (It is tempting to relate this approach to a previous treatment of dielectric loss in vitreous materials which invoked the Debye–Falkenhagen effect[11].)

It is difficult to say that either of these explanations is 'right' and the other 'wrong'. Thus, according to the Jonscher model, highly 'lossy' electrolytes, such as β-alumina, need a high concentration of mobile ions to give effective charge-screening, but these are precisely the electrolytes which have a strong tendency to cation disorder and hence are likely to exhibit a wide spread in ionic jump frequencies[12]. The main point which emerges from the above discussion is a need for further detailed comparisons of structural, spectroscopic and electrical data, and hence the need for work with crystalline rather than vitreous systems. β-alumina is in many ways a model system, since measurements can be made over a wide range of d.c. conductivities, and extensive cation substitution is possible[13,14].

The behaviour of long molecules diffusing in solid polyethylene

SEMI-CRYSTALLINE polymers, according to the current two-phase model, consist of an impermeable, denser crystalline phase (the lamellae) and a permeable, less dense amorphous phase (the interlamellar regions)[1]. All permeation and transport properties occur predominantly in the latter, and are a function of the overall amorphous fraction within the bulk and the geometry of the crystallites embedded in the amorphous phase. For linear polyethylene cooled at various rates from the melt, the diffusion coefficient D of gaseous diffusants varies[2,3] according to

$$D \propto (1 - x), \qquad (1)$$

where x is the corresponding crystalline volume fraction, and $(1 - x)$ the amorphicity. The diffusional behaviour of long chain diffusants, however, may be very different. For example, it has been suggested[1] that the transport of long chain molecules through the disordered interlamellar regions of polythene will be greatly influenced by the presence of interlamellar tie-molecules and entanglements. These are relatively immobile features in the disordered region which can obstruct the movement of long chain molecules, but not that of smaller (for example, gaseous) diffusants if their size is less than the separation between these features. An extension of de Gennes' ideas on reptation[3] gives a semiquantitative relation for the diffusion coefficient of long molecules in polyethylene: long molecules should diffuse faster in slowly cooled than in quenched polyethylene, in spite of the higher disordered fraction in the latter and in marked contrast to the behaviour of gaseous or light vapour diffusants, because rapid cooling results in a greater profusion of fixed tie-molecules[6], which constrain long diffusants but have little effect on small ones. We report here results which support this model.

We measured D for two linear diffusants of the form $n-(CH_2)_NX$, X being a suitable label and $N \simeq 25$ or 45. The matrix was linear polyethylene cooled at two widely differing rates from the melt. The measuring technique was one we have recently developed, based on infrared microdensitometry[7], and involves setting up a known concentration distribution of diffusant within the host matrix, allowing it to broaden for a known time t at the required temperature, then measuring the resulting diffusion-broadened concentration profile. D can be evaluated knowing the shapes of the two profiles as well as t; Fig. 1 shows experimental profiles at the beginning and end of a typical diffusion run: the calculated curves (with the appropriate value of D) when superimposed on the experimental ones, show a good fit.

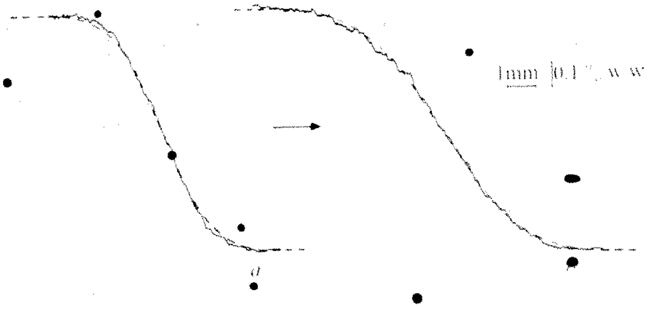

Fig. 1 Concentration–distance profiles as measured (—) at the beginning (*a*) and end (*b*) of a typical diffusion measurement. ----, calculated shapes as evaluated with the appropriate value of D. ($t = 1.29 \times 10^6$ s at 91 °C; the diffusant is a linear molecule of form $n-(CH_2)_{23}X$, X being an ester group; the matrix is linear polyethylene cooled rapidly from the melt, and the scanning frequency corresponds to the ester group absorption peak at 1720 cm^{-1}. D evaluated as 1.3×10^{-8} $cm^2 s^{-1}$.)

Table 1 summarises some of the results, giving D for the two diffusants in both rapidly and slowly cooled polyethylene matrix, and the corresponding values of the crystallinity x as derived from density measurements. In Table 2 we compare the prediction of the model (outlined above), which takes into account the topological constraints on the diffusants, with the experimental results (details of the calculations are given elsewhere[5]). The predictions of the simple two-phase relation, equation (1), are also shown.

Table 2 shows that agreement between observed and predicted ratios is fair to good. In particular, the model predicts correctly that D for the long diffusants used increases in the slowly cooled, more crystalline matrix—in contrast to equation (1).

The results provide support for the concept that long diffusants in semi-crystalline polymers may be constrained in a way which small diffusants are not; they suggest that studies involving such diffusants could yield information on the nature of the disordered phase in these polymers not otherwise available.

Table 1 D (in units of 10^{-9} $cm^2 s^{-1}$) for diffusants of form $n-(CH_2)_NX$* in linear polyethylene, at 84.8 °C

No. of backbone units N	Rapidly cooled matrix	Slowly cooled matrix
$N \simeq 45$	3.3 ± 0.4	6.5 ± 0.7
$N \simeq 25$	9 ± 1.8	11 ± 1.8
Crystalline volume fraction, x	0.751	0.855

*X is an ester group.

Table 2 Calculated and observed values of D for diffusants of form n-$(CH_2)_NX$ in linear polyethylene matrix at 84.8 °C

(a) Variation of D with cooling rate of matrix

No. of backbone units N:	D (slowly cooled matrix)/D (rapidly cooled matrix) Calculated	Observed	'2-phase', $D \propto (1-x)$
$N \simeq 25$	1.26	1.2 ± 0.3	0.58
$N \simeq 45$	1.52	2.0 ± 0.3	0.58

(b) Variation of D with diffusant length

	Rapidly cooled matrix Calculated	Rapidly cooled matrix Observed	Slowly cooled matrix Calculated	Slowly cooled matrix Observed
$\frac{D_{N\simeq 25}}{D_{N\simeq 45}}$:	2.18	2.7 ± 0.5	1.80	1.7 ± 0.3

Detailed accounts of both theory[1] and experiment[2] are in press.

J.K. thanks Professor Sir Samuel Edwards for discussions, and we thank Professor D. Tabor for encouragement. We also thank RAPRA for the polyethylene and Mr Tom Connelly for help with density measurements. New transient effect observed in rock samples subjected to simulated upper crustal conditions

WHILE making laboratory measurements of the electrical conductivity (σ) of rock samples subjected to temperatures, confining pressures, and pore fluid pressures thought to be appropriate to depths up to 15 km within the Earth, we have observed a hitherto unreported transient behaviour which is only revealed by the simultaneous application of pressure and temperature, and leads to an irreversible decrease in σ with time which could be due to compaction of the rock samples. We suggest that only after such a change has occurred is the condition of rocks collected near the Earth's surface more representative of those at depth in the crust.

Most of the rock samples used in this study are high-grade metamorphics from the Lewisian of NW Scotland, which have a very low porosity (< 1%). These were cored, cut and ground into cylinders of diameter 24.5 mm and length 10–20 mm, and saturated with a 0.5 or 0.05 M sodium chloride solution. Two stainless steel electrodes allowed the a.c. conductance (normally at a frequency of 1.5 kHz) between the sample faces to be measured using a Wayne-Kerr B224 transformer bridge. Confining pressure acting on a rock within the Earth (due to the column of rocks above it) was simulated by hydrostatically pressurising the sample (up to 0.4 GPa (4 kbar)) in a pressure vessel. To prevent contamination from the oil pressure-medium the sample and electrodes were sheathed with a Teflon tube. It is believed that most rocks have sufficient strength to prevent their pores shutting completely under such pressure[1], and it is possible therefore for the pore fluid pressure to differ from the confining pressure. To allow for this, a hole passing through one electrode to the surface of the rock sample was connected to a pipe which passed out of the vessel, enabling the pore fluid pressure to be varied independently of the confining pressure. A furnace around the sample allowed temperatures up to 275 °C to be reached.

Because the bulk of the measured conductance in saturated rocks occurs through the solutions within the fine pore network, small changes in pore structure have a considerable effect on σ (refs 1, 2), and as σ can be measured accurately, it is probably the most sensitive property to use to investigate such small structural changes. Increasing the confining pressure closes up this pore structure, while increasing the pore fluid pressure has the opposite effect. It is reasonable therefore to assume a model in which the parameter that determines the overall pore structure, and therefore σ, is the pressure differential (known as the effective pressure) between confining and pore fluid pressure[3,4]. Most of our results at room temperature conformed to this model, with σ showing a steady decrease as the effective pressure was increased.

Figure 1 shows the typical behaviour observed when a sample at a fixed effective pressure was heated. From its room temperature value (a), σ increased along the path a–b as the temperature was increased. We found, however, that if the temperature was held steady at a high enough temperature (b), σ fell over a period of time to a lower value (c). This drop b–c did not occur suddenly at any specific temperature, and a slight drop has even been observed at temperatures as low as 130 °C, although at a very slow rate. Increasing the temperature has the effect of accelerating the rate, and samples were normally heated to around 200 °C or above, to enable us to observe a drop in a reasonable period of time. Figure 2a shows the time dependence

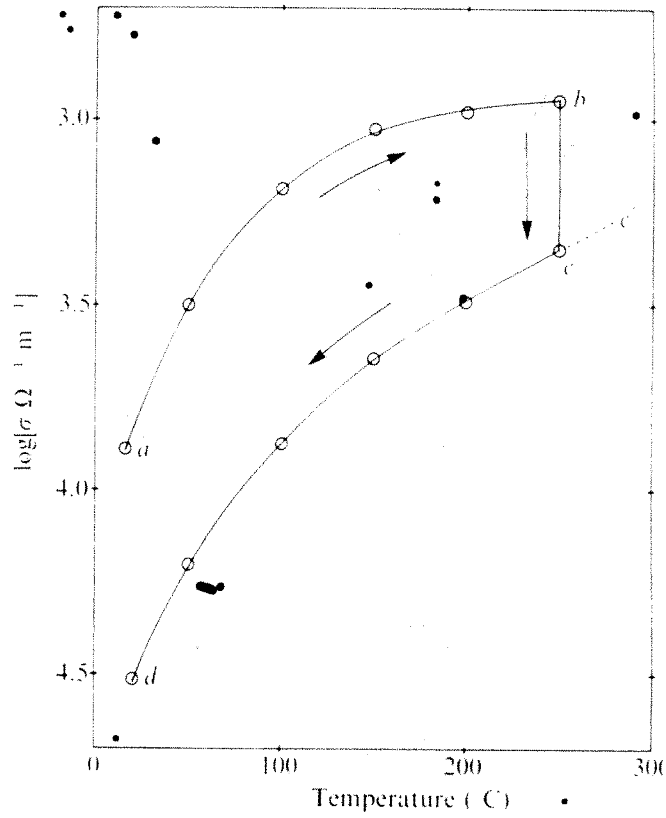

Fig. 1 Irreversible change in conductivity during the initial temperature cycle of a sample of gneiss saturated with 0.5 M NaCl solution and subjected to an effective pressure of 0.2 GPa (2 kbar).

of σ in one sample during the period of the drop. On cooling, the path c–d was followed. With any further increase or decrease in temperature, σ remained on the curve d–c, even when the temperature was increased beyond the point c to c', indicating that the rock had suffered some irreversible change. Although the rate of the drop varied from sample to sample, the general cycle *abcd* was observed in all saturated samples investigated. The feature does not seem to be confined to the very low porosity rock type used, since samples of basalt (2% porosity) and pyrophyllite (7% porosity) also showed a similar drop. Only in a sample pre-baked to remove any natural pore fluids was there no discernible drop in σ at high temperatures. Spurious effects, such as conduction paths between the rock and the Teflon sleeve, were discounted after making measurements with non-porous plugs (Teflon or sapphire) replacing the rock sample.

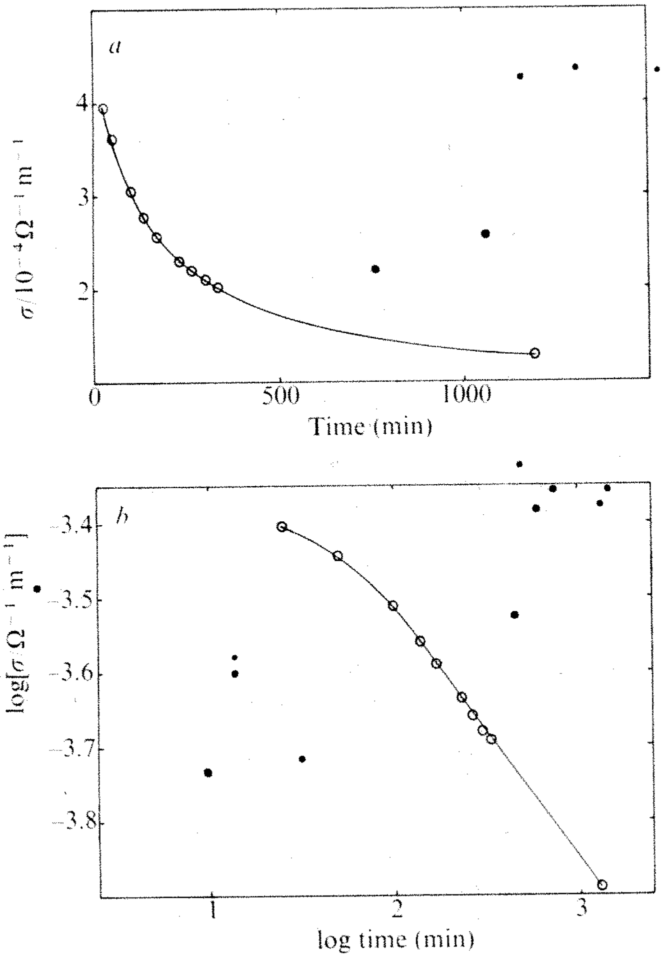

Fig. 2 Time dependence of the conductivity for a sample of granite gneiss (saturated with a 0.5 M NaCl solution) when subjected to an effective pressure of 0.35 GPa (3.5 kbar) at a temperature of 190 °C.

We believe a possible explanation for this behaviour is that in its initial state a, the sample contains many cracks and flaws associated with near-surface conditions such as weathering and unloading (and possibly with rock sampling and preparation)[5]. At room temperature, the strength of a rock is sufficient to prevent many of these cracks closing under pressure, but at elevated temperatures, the strength of a rock decreases, allowing more of the initial cracks to close and leaving the rock in a more compacted state. Figure 2b shows that apart from the initial period of the drop (where there is uncertainty in the precise onset), the variation of σ with time (t) may be expressed by the equation:

$$\log \sigma = A + B \log t,$$

where A and B are constants dependent on rock type, and the temperature and pressure conditions.

It has often been observed in transient creep measurements on rocks subjected to differential stress, that strain (ε) is also proportional to log t (refs 6, 7). If it could be shown, therefore, that a linear relationship exists between log σ and ε, it is possible that the drop we observe in log σ, when held at high pressure and temperature, may also be due to creep behaviour. Such a relationship might be argued as follows. In saturated rocks, it is found experimentally[1,2] that at moderate pressure (p),

$$\log \sigma \propto p.$$

Furthermore, from strain measurements made under such pressures[1],

$$\varepsilon \propto p.$$

Thus, it seems reasonable to assume that for any strain (whether elastic or inelastic)

$$\log \sigma \propto \varepsilon.$$

If this is the case (that is, that this transient behaviour is a sensitive indicator of a creep process), then presumably it is important to simulate this effect by thermal cycling of a rock sample under pressure before truly meaningful measurements of various physical properties of rocks can be made under laboratory conditions. To investigate this possibility, we are presently making simultaneous measurements of acoustic velocities and electrical conductivity in rocks, under the same conditions as described earlier, to examine whether the transient behaviour in σ reported here may also be observed in acoustic velocity measurements.

Peridotite–CO_2–H_2O, and carbonatitic liquids in the upper asthenosphere

The recent discovery that CO_2 at upper mantle pressures has a dramatic effect on the melting temperature of peridotite (because the silicate assemblage becomes carbonated), and on the composition of near-solidus liquid, has petrological and geophysical implications that have been explored extensively. The influence of H_2O has received only passing reference, probably because it was tacitly assumed that this would modify the carbonate-dominated melting relationships significantly. I describe here construction of a schematic diagram for the system peridotite–CO_2–H_2O which shows that the carbonate can persist even in the

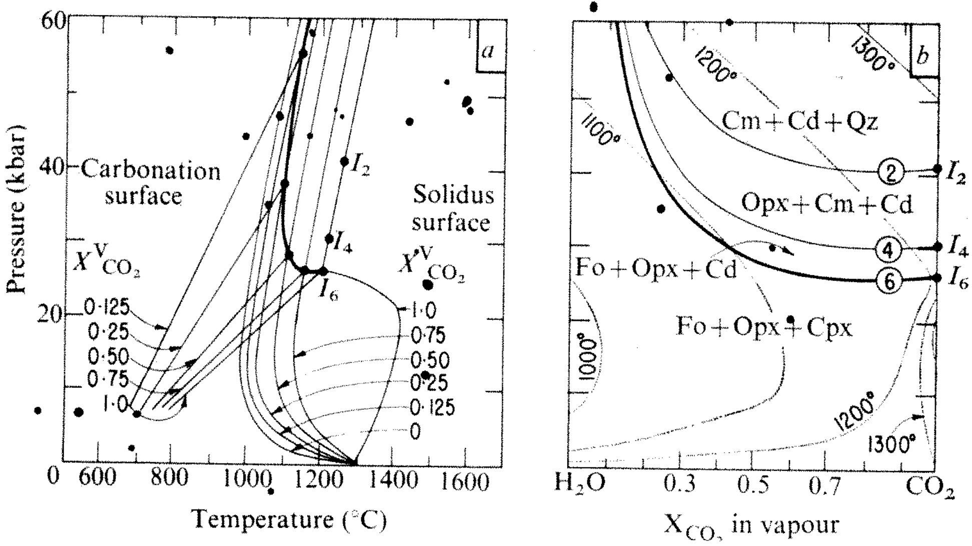

Fig. 1 Schematic phase diagram for the system peridotite–H_2O–CO_2, assuming a simple peridotite composition, Fo = 65%, Opx = 23%, Cpx = 12%. This illustrates the geometry for intersection of a divariant subsolidus carbonation reaction with the divariant solidus surface for melting in the presence of CO_2–H_2O vapours. It represents a compromise among several sets of experimental data, and precise pressures and temperatures need experimental determination (see ref. 21 for modifications of data from refs 5, 6, 10, 12, 13, 22). *a*, *P–T* projection. The univariant carbonation reaction extending to lower pressures and temperatures from I_6 is: (6) Cpx+Fo+CO_2 = Opx+Cd (calcite dolomite)[4–6]. In the presence of CO_2–H_2O vapours this reaction becomes a divariant surface extending to higher pressures and lower temperatures; it is mapped by contours for constant vapour-phase composition. Curves for the beginning of melting of peridotite in the presence of water[23] and CO_2[4,5,6] are connected by a curved surface, mapped in terms of contours for constant vapour-phase composition[10]. *b*, *P*–X projection (X is molar fraction). This shows the solidus surface, with estimated temperature contours. Vertical lines in this projection correspond to the contours in (*a*). The heavy line (6) corresponds to the intersection line of the two surfaces illustrated in (*a*). The lines (4) and (2) refer to other carbonation reactions[4,5] that are not encountered for reasonable mantle peridotite compositions, with low CO_2 contents. Mantle vapour-phase compositions are buffered to remain on the divariant carbonation surface of (*a*). Therefore at pressures (depths) greater than I_6, carbonate is stable in peridotite with total CO_2/H_2O ratios greater, at a given pressure, than the heavy line (6) in (*b*); similarly, vapour-phase compositions within the heavy line of (*b*) do not exist in the mantle at the pressures indicated. Abbreviations: Cm, magnesite solid solution; Qz, SiO_2 polymorphs.

presence of vapours with high H_2O/CO_2. Figure 1 shows that starting with peridotite–H_2O at high pressures, a small addition of CO_2 is sufficient for the generation of carbonate. This leads to the unexpected conclusion that many of the applications deduced for the melting of carbonated peridotite may remain valid with vapours enriched in H_2O/CO_2. In particular, the interstitial liquid in the upper part of the seismic low-velocity zone may be carbonatitic even with H_2O present as a component.

Until recently, it was believed that the solubility of CO_2 in mantle magmas remained low as it does in crustal magmas[1,2]. Experimental studies in silicate–CO_2 and silicate–carbonate systems have shown that peridotite becomes carbonated by the reaction Cpx+Fo+CO_2= Opx+Cd at high pressures[3–6] (Fo, forsterite; Cd, calcic dolomite; Opx, orthopyroxene; Cpx, clinopyroxene), and this causes a remarkable increase in the CO_2-solubility of near-solidus liquids[4,7,8]. The composition of the liquid produced by melting of the silicate–carbonate assemblage along the peridotite–CO_2 solidus rising from I_6 in Fig. 1*a* is 'carbonatitic' according to Wyllie and Huang[4,5,7], with CO_2 solubility approaching 40%, and 'kimberlitic' according to Eggler[6,8], with CO_2 solubility about 20%. Certainly, the CO_2 solubility is remarkably high, and the liquid composition is markedly different from that of normal basaltic magmas.

There is now convincing evidence that both H_2O and CO_2 do exist in the upper mantle[9–11] and it has been shown experimentally that the proportion of CO_2/H_2O influences the SiO_2 content of near-solidus liquids generated from mantle peridotite[10,12,13]. Figure 1 illustrates the effect of H_2O on the phase relationships for peridotite–CO_2; the geometrical relationships are correct although specific values for pressure and temperature need experimental determination.

It is assumed that the peridotite composition is not suitable for the stabilisation of amphibole and phlogopite, so that we can examine the influence of carbonate alone. Consider a partially carbonated peridotite composed of Fo+Opx+Cpx+Cd in the presence of a small amount of CO_2–H_2O vapour. This system must be situated on the divariant carbonation reaction surface and, at a given pressure and temperature, the vapour phase composition is given by the contour passing through the *P–T* point on the surface. With increase in temperature, decarbonation proceeds releasing CO_2 so that the CO_2/H_2O ratio in the vapour maintains the system on the surface. Similarly, carbonation occurs with increase in pressure, enriching the vapour in H_2O/CO_2. The principle is well established in metamorphic systems[14,15]; the vapour phase composition is buffered by the mineralogy.

The system can leave the surface for divariant reaction (6 in Fig. 1) only if carbonation or decarbonation are completed. The first alternative requires complete reaction of 12% clinopyroxene, which is most unlikely for any reasonable CO_2 content in mantle peridotite; therefore, the system cannot enter the high-pressure volume for complete carbonation in Fig. 1*a*, which meets the solidus surface in the area at pressures above the heavy line in Fig. 1*b*.

At a given pressure above I_6, the vapour phase in partially carbonated peridotite at its solidus temperature is constrained to lie on the solid line (6) in Fig. 1*b* (compare its position in Fig. 1*a*). For peridotite without crystalline carbonate, the vapour phase at the solidus temperature may have any composition at pressures below I_6, but it is limited to the higher H_2O/CO_2 ratios to the left of the heavy line (6) in Fig. 1*b*.

For the system peridotite–CO_2 at pressures above I_6, I am convinced that the near-solidus liquid is carbonatitic becoming kimberlitic with increasing temperature[4,5,7] (contrast Eggler). From the scanty data available in silicate–carbonate–CO_2–H_2O systems[16–18], I anticipate that the liquid composition at the solidus is dominated by the silicate–carbonate assemblage; any H_2O in the vapour dissolves in this liquid, with relatively little influence on the liquid composition. Accordingly, the liquid produced from the peridotite–carbonate assemblage could remain 'carbonatitic', even in the presence of H_2O/CO_2-enriched vapours. At pressures below I_6, near-solidus liquids become more siliceous with increasing H_2O/CO_2[10,13]. At pressures above

I_6, this is true also for the range of vapours coexisting with uncarbonated peridotite. Using the schematic phase diagram of Fig. 1 as a guide, we can reach the following conclusions.

For a partially carbonated mantle peridotite of fixed composition in thermal equilibrium, it can be determined from Fig. 1 that the amount of carbonate in the lithosphere decreases with depth, and the ratio of CO_2/H_2O increases in the vapour phase. If a portion of the mantle rises from the geotherm under adiabatic conditions, the amount of carbonate decreases, and the ratio of CO_2/H_2O in the vapour increases as the peridotite rises to shallower levels.

For a partially carbonated mantle peridotite, coexisting vapours have fairly high ratios of H_2O/CO_2 (Fig. 1*b*). Incipient melting begins with the generation of carbonatitic liquid. The liquid at the top of the seismic low-velocity zone may therefore be carbonatitic, with 10–15% dissolved silicates, Ca/Mg>1, and probably enriched also in alkalis and a host of trace elements. At greater depths, this grades into liquids with kimberlitic affinities. Carbonatitic liquids are very fluid, and they would probably migrate upwards. Local concentrations, and intrusions into the overlying peridotite, could produce a layer of lithosphere enriched in crystalline carbonates

This picture is consistent with a tentative proposal[19] that kimberlite magmas may be mixtures of silicate liquids from within the asthenosphere with carbonatitic liquids from near the top of the asthenosphere It is also consistent with the suggestion[20] that carbonatite magmas could be the fluids involved in the fluidisation emplacement of some kimberlites. For mantle peridotite with compositions appropriate for the formation of phlogophite, vapour phase compositions must be buffered by subsolidus reactions between phlogopite and carbonate in the presence of Fo+Opx+Cpx, which remain to be determined[21]. Alternatively, all CO_2 and H_2O may be stored in phlogopite and carbonate, with no free vapour phase.

3-Gyr-old stromatolites from South Africa

WE report here a new record of early Precambrian stromatolites from the 3·0-Gyr Pongola Supergroup of South Africa (Fig 1), which is exposed in parts of the southeastern Transvaal, Swaziland, northern Natal and Zululand. These rocks occur in an almost complete section found in the Wit-Mfolozi River valley, about 200 km north of Durban. In that part of Natal the volcanic–sedimentary Pongola Supergroup attains a maximum thickness of about 2,500 m. It is subdivided into two distinct north-east-dipping stratigraphic units, the lower 1,800-m thick Insuzi Group and the upper 700-m Mozaan Group[1]. Bedding and primary sedimentary structures are ubiquitously well preserved Deformation is restricted to moderate cleaving of the argillaceous rocks. Evidence of regional metamorphism is restricted to incipient recrystallisation of the arenaceous and carbonate rocks; the lavas show evidence of deuteric alteration. Contact metamorphism is found where isolated diabase sills intrude the strata.

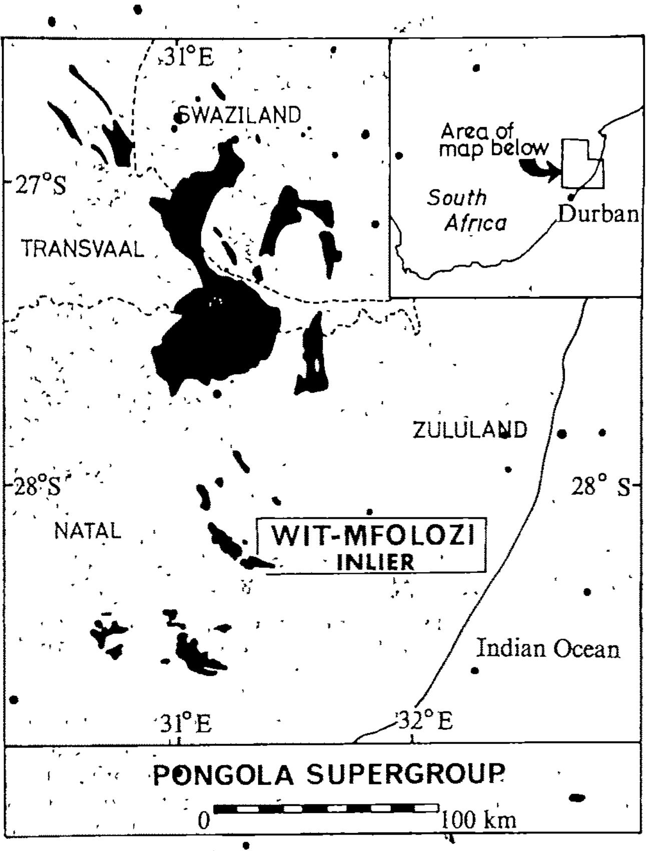

Fig. 1 The distribution of Pongola Supergroup exposures in the southeastern Transvaal, Swaziland, northern Natal and Zululand.

The Insuzi Group rests nonconformably[2] on crystalline basement rocks and comprises a repetitive sequence of quartz arenites and dolomites, with subordinate siltstone–mudstone units. The carbonates are of particular interest as no other recorded Insuzi Group exposures contain dolomites They vary in thickness (1–30 m), and are laterally impersistent, forming units in the succession which are only of local importance. Amygdaloidal lavas occur near the base and at the top of the Insuzi Group. The siliciclastic sediments provide evidence for deposition in a tide dominated environment, as they contain sedimentary structures including, lenticular, flaser and wavy bedding, mudclast conglomerates, herringbone cross lamination, and ripple marked bedding surfaces displaying desiccated mud drapes within their troughs Palaeocurrent data suggest that the coastline lay to the north. The unconformably overlying Mozaan Group is entirely composed of siliciclastic sediments of tidal origin and contains sedimentary structures similar to those noted in the Insuzi.

The stromatolites occur within Insuzi carbonates and resemble those recorded from the northern Slave Province (2·5 Gyr) of Canada[3] as they are generally of low relief, rarely rising more than a few cm above the contemporary substrate They form undulatory surfaces which are accentuated by the partial silicification of the host dolomite. Silicification was selective and not wholesale, so that instead of destroying the finer fabric of the rock this has been enhanced. The stromatolites commonly form low domes

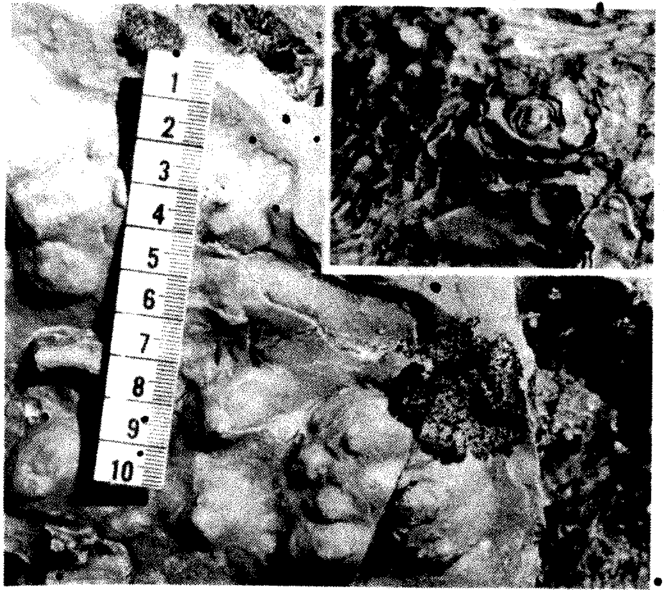

Fig. 2 Low relief domical stromatolites exposed on a bedding surface. Inset at same scale, exfoliated dome showing laminated structure.

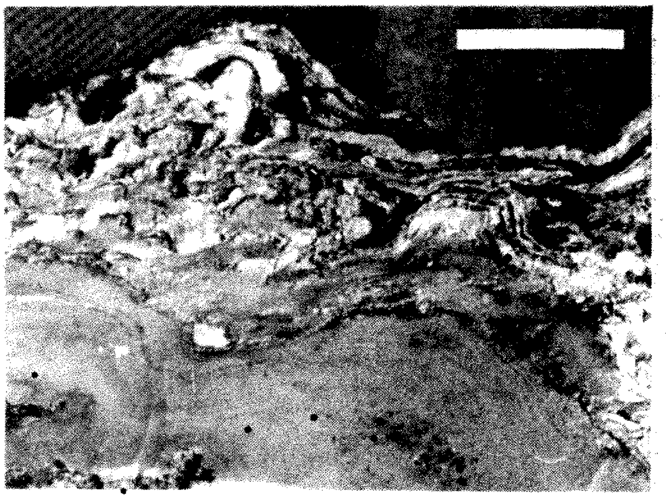
(Figs 2, 3) and may be classified according to their geometry[4]. LLH-S, LLH-C and SH types have been recognised. The structures are thought to be of biogenic origin for a number of reasons. First, the preponderance of convex-upwards structures are strongly reminiscent of the growth habits of Recent algal communities. Second, the ubiquitous fine mm scale laminations in the rock are considered to be diagnostic of former algal growth[5], a conclusion reinforced by microscopic examination which reveals occasional fine sandy layers trapped between successive laminae (Fig. 4). A direct analogue of this feature may be found in the sediment trapping and binding habits of Recent blue-green algal mats[6]. Finally, some of the samples also display fenestral textures, with coarse sparry dolomite filling former voids in the rock. In Recent examples of algal sediments fenestrae are interpreted as structures formed by the interaction of algal mat and algal bound sediment. Desiccation, oxidation and lithification are also important factors leading to the formation of fenestral textures[7].

Characteristic sedimentary structures in the dolomites provide further evidence of shallow-water sedimentation. In the quartz arenites large dolomite clasts are found (about 30 cm) incorporated in the sandy sediment. They seem to have been reworked from adjacent carbonate mud flats by currents of considerable velocity. In addition, intraclastic dolomites suggest that there was significant penecontemporaneous reworking of the carbonates and, as these rocks contain herringbone cross lamination, tidal action was the most likely cause.

Fig. 3 Weathered surface showing a section through stromatolite structures. Note the differential erosion of the silica and carbonate layers, and the very fine lamination in the more massive silica at the bottom of the photograph. Scale bar 1 cm.



Insuzi Group stromatolites are of particular interest considering the scarcity of biogenic structures of this age in the geological record. Five comparable occurrences are documented, two in Canada[3,8] and three in Rhodesia[9,10]. The age of the Insuzi Group is not precisely defined. The overlying Mozaan Group rests with a sedimentary contact on the 3.06-Gyr (Rb/Sr) Lochiel granite of the southeastern Transvaal[11], and is intruded by the Usushwana Complex dated at 2.87 Gyr (ref. 12). Zircons from the Insuzi lavas at Nkandhla gave an age of 3.09±0.09 Gyr (ref. 13) and a whole rock Rb/Sr age of 3.15±0.15 Gyr is reported from Insuzi felsites[13] in the Mozaan valley of Swaziland. From the foregoing evidence there seems little doubt that the Insuzi Group is approximately 3.0-Gyr-old. Comparing this date with the ages generally quoted for the other five localities we find that the age of the stromatolites at Steeprock, Ontario, is in dispute, while those of the northern Slave Province[3] (2.5 Gyr) post-date the Pongola. Work on the Rhodesian greenstone belt[10,14,15] suggests that the Bulawayan and Belingwe stromatolites are about 2.6–2.7-Gyr-old. Assuming that this age is correct, and that it does not represent the resetting of the radiometric clocks by the most recent metamorphic event, the Insuzi stromatolites are the oldest so far documented.

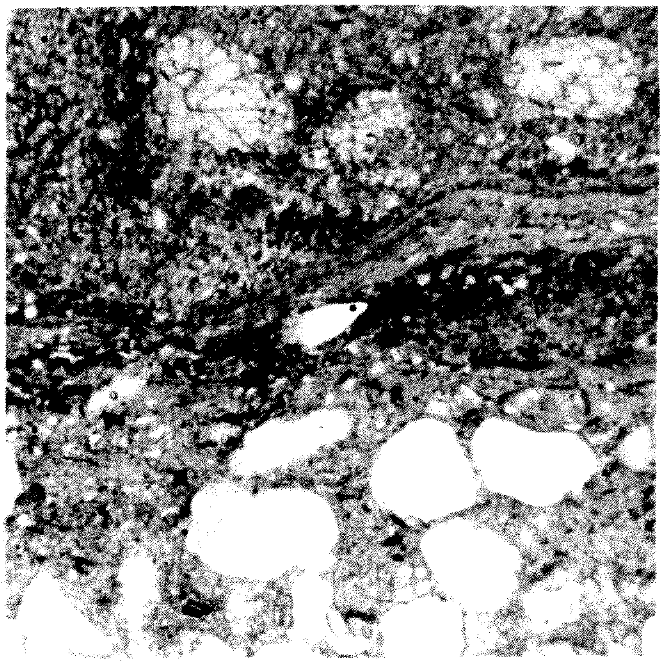


Fig. 4 Fine sandy layer trapped within laminated stromatolite. Note sparry dolomite filling former voids in the rock. Magnification ×70.

Considering the criteria of emergence and shallow water sedimentation found in the quartz arenites in the Wit-Mfolozi section and the evidence for marine deposition provided by the stromatolites, there is little doubt that the Insuzi Group was deposited in a tidally influenced environment. Von Brunn and Hobday[16], applying Klein's[17] model to other Pongola exposures in this region, concluded that the palaeotidal range lies between 12 and 25 m. In the area under discussion comparable palaeotidal amplitudes are suggested by similar sedimentary sequences. Such large amplitudes may have relevance to hypotheses concerning the capture of the Moon by the Earth. The relationship between the stromatolite-bearing carbonates and evidence of extensive volcanicity is also of note. In all the other early Precambrian occurrences, stromatolites are associated with lavas, and we speculate that the exhalative activities of lava extrusions provided optimum conditions for stromatolite growth. The Earth's atmosphere at the time was probably anaerobic[18], and some Recent algal species can thrive in such an environment. If ancient stromatolites produced oxygen by photosynthesis, this could have been immediately removed from the environment as free oxygen, and transported to one of the oxygen sinks then operative. The thin banded ironstones in the overlying Mozaan might owe their presence to the local production of biogenically derived oxygen during those times.

Cloud[19] adapted many of his former ideas concerning the major features of crustal evolution to account for the anomalous presence of banded ironstones and stromatolites in the Pongola. He suggested that the events taking place in southern Africa in the early Precambrian were out of phase with those of the rest of the planet in that they anticipated many later developments in other areas.

We thank Professors R. Tavener-Smith and D. R. Hunter for reading the manuscript.

Pigmentation of the ladybird beetle *Coccinella septempunctata* by carotenoids not of plant origin

MANY insects contain carotenoid pigments[1], and some notable examples are found in the Coleoptera, where carotenoids are responsible for the yellow colour of the yellow and black striped wing cases of the Colorado beetle, *Leptinotarsa decemlineata*, and the orange-red colour of the ladybird beetles, *Coccinella* spp. There has, however, been no report of any insect species being able to synthesise carotenoids *de novo*, and it is generally accepted that in insects, as in other animals, any carotenoids present are of dietary origin[2]. In July 1976 the Liverpool area, like many regions of the UK, experienced an invasion by enormous numbers of ladybirds, almost entirely of the seven-spot variety, *Coccinella septempunctata*. With such large numbers of insects available we were able to use modern analytical techniques to identify the carotenoids of these beetles. We report here that the carotenoids identified were mostly hydrocarbons, and the carotenoid pattern indicated that these pigments in the ladybird are likely to be of microbial rather than plant origin, thus suggesting the involvement of symbiotic microorganisms.

Preliminary thin-layer chromatographic analysis showed that the carotenoid composition of isolated red wing cases (elytra) was the same as that of the entire insect, so whole insects were used in the large-scale analyses. Carotenoid hydrocarbons formed the bulk of the pigment, but there were also small amounts of many xanthophylls, of which only lutein (β, ε-carotene-3,3′-diol) was identified with certainty. The carotenes were characterised by chromatographic properties, light absorption and mass spectra, and whenever possible by comparison with authentic samples. Eighteen compounds were identified, including β-carotene (β,β-carotene), previously reported by Lederer[3] and by Valadon and Mummery[4]. One of the main carotenes present was torulene (3′,4′-didehydro β,ψ-carotene), and smaller amounts of γ-carotene (β,ψ-carotene), β-zeacarotene (7′8′-dihydro-β,ψ-carotene), 'cyclic ζ-carotene' (7′,8′,11′,12′-tetrahydro-β,ψ-carotene), lycopene (ψ,ψ-carotene) and 3,4-didehydrolycopene (3,4-didehydro-ψ,ψ-carotene) were present. A second series of compounds present possessed a methylenecyclohexane ring system (γ-ring) (ref. 5), a very unusual structural feature. β,γ-Carotene, γ,γ-carotene, γ,ψ-carotene, 3′,4′-didehydro-γ,ψ-carotene, 7′,8′-dihydro-γ,ψ-carotene and 7′,8′,11′,12′-tetrahydro-γ,ψ-carotene were all identified. The natural occurrence of the last three of these carotenoids has not been reported previously. A series of more saturated acyclic compounds that are intermediates in carotenoid biosynthesis[6] was identified—phytoene (7,8,11,12,7′,8′,11′,12′-octahydro-ψ,ψ-carotene), phytofluene (7,8,11,12,7′,8′-hexahydro-ψ,ψ-carotene), neurosporene (7,8-dihydro-ψ,ψ-carotene) and 'ζ-carotene' (a mixture of symmetrical 7,8,7′,8′,-tetrahydro-ψ,ψ-carotene and unsymmetrical 7,8,11,12-tetrahydro-ψ,ψ-carotene). The carotenoids present in the largest amounts were torulene and β,β-, β,γ-, β,ψ- and γ,ψ-carotenes.

Phytoene, phytofluene, 'ζ-carotene', neurosporene, 'cyclic ζ-carotene' and β-zeacarotene are possible intermediates (as are lycopene and γ-carotene) in the biosynthesis of β-carotene, and have not been detected before in any insect or other animal. The presence of lycopene in the ladybird has finally been proved, long after evidence for its occurrence was first reported[3]. The γ-ring carotenoids and the carotenes of the torulene series are also unusual and their presence in an animal is surprising.

The question of the origin of these pigments cannot be answered in terms of the accepted view that insect carotenoids are of dietary origin[2]. The food chain involving the ladybird is short and simple. The beetles feed on aphids which in turn feed on the juices of green plant tissues. Within this food chain only the green plants are known to be capable of synthesising carotenoids, and there is no known metabolic process whereby the bicyclic compounds with β- and ε-rings, produced by the plants, could be transformed into acyclic, monocyclic or γ-ring carotenes. The ladybird carotenes must therefore originate elsewhere.

The γ-ring carotenes, β,γ-carotene and γ,γ-carotenes, together with β-carotene have, however, been isolated from a green variant of the aphid, *Macrosiphum liriodendri*, whereas pink variants of the same species contained β-carotene, γ-carotene, torulene, lycopene and 3,4-didehydrolycopene[7]. We stress that the ladybirds used in our investigation were members of a huge, migratory, starving population, and nothing was known of their previous food intake. Although it is unlikely that the ladybirds or their larvae would have had access to the aphid species *M. liriodendri*, which seems to be a specific parasite of the tulip tree (*Liriodendron tulipifera*), it is not unreasonable to expect that the γ-ring and torulene series carotenoids may be present in other species of aphid which may have formed part of their diet. Even so, the aphids themselves could not obtain these carotenes from the green plants on which they feed.

We therefore conclude that these carotenes are synthesised within the aphid and/or the ladybird. The possibility of synthesis *de novo* by the insect cannot be ruled out, although this would be the first instance to be discovered of carotenoid synthesis by any animal. The involvement of symbiotic microorganisms seems more probable, and the nature of the carotenoids present gives indirect support for this theory. Apart from these reports of their occurrence in the insect species, γ-ring carotenoids have been found only in a discomycete fungus *Caloscypha fulgens*[8]; torulene and related compounds are the characteristic pigments of red yeasts (*Rhodotorula* spp.)[9]. Further, the 'ζ-carotene' isolated from ladybirds was a mixture of the symmetrical and unsymmetrical isomers, a situation encountered commonly in bacteria and fungi but not normally found in higher plants[10]. Weisgraber *et al.*[11] have summarised evidence which they believe suggests strongly that the γ-ring and torulene series carotenes present in the aphid *M. liriodendri* are of microbial origin, and aphids in general are rich in symbionts (yeasts, bacteria, etc.) some of which are red[12].

For the ladybird, many of the carotenes present could presumably have been derived from aphids (or their symbiotic microbes) devoured by the beetles, but it seems unlikely that phytoene and the other desaturation and cyclisation intermediates would be absorbed and accumulated by the ladybird if they were obtained only in minute amounts in its food Their presence suggests a site of synthesis within the ladybird itself. Although no information is available about the microflora of the ladybird, it is reasonable to believe that carotenogenic microorganisms present in its aphid prey could be acquired and cultivated by the beetle. Thus it is likely that the carotenoids responsible for the characteristic red colour of *C. septempunctata* are synthesised within the insect, probably through an association with symbiotic microorganisms. Preliminary analysis indicates that the situation may be similar in other species of ladybird.

We thank Dr Noel Arpin for providing β,γ-carotene from *Caloscypha fulgens* for comparison.

Naturally occurring viral R plasmid with a circular supercoiled genome in the extracellular state

PHOTOSYNTHETIC bacteria have been used extensively in studies on photosynthesis, photochemical nitrogen fixation and photoevolution of hydrogen A major obstacle to combined biochemical and genetic studies of these processes is a lack of knowledge of gene transfer in such bacteria. The only transfer mechanism known is that reported by Marrs for the facultative phototroph *Rhodopseudomonas capsulata*[1]. In this bacterium gene transfer is mediated by a filterable agent of small size (Gene-Transfer-Agent) estimated to carry between 10^5 and 10^6 daltons of DNA; the nature of these GTAs is unknown Although GTAs have been used to construct a preliminary map of the bacteriochlorophyll and carotenoid biosynthetic genes in *R. capsulata* (ref 2), the small amount of DNA transferred limits their usefulness in genetic analysis To obtain alternative means of gene transfer we examined isolates of the closely related species *R. sphaeroides* for temperate transducing bacteriophage and conjugative R plasmids.

Several temperate, but evidently non-transducing bacteriophage have been isolated from *R. sphaeroides* (ref. 3) and *R capsulata* (ref. 4) Many of our wild type isolates carry between one and three prophages and more than 90% are resistant to penicillin because of a diffusible penicillinase (unpublished data) Since the production of diffusible penicillinases by *Staphylococcus aureus*[5], *Pseudomonas aeruginosa*[6] and various enteric bacteria[7] is encoded by plasmid genes, extrachromosomal DNA isolated from *R. sphaeroides* (refs 8, 9) could constitute extrachromosomal prophages and/or penicillinase plasmids.

Initial experiments with a penicillinase-producing strain of *R sphaeroides* RS601 (prototrophic, penicillin resistant) showed that a sensitive mutant RS602 (prototrophic, penicillin sensitive), isolated after treatment with the mutagen nitrosoguanidine, was 'cured' of a prophage. Bacteriophage released spontaneously by the wild type RS601 (10^5–10^6 plaque-forming units per ml of supernatant) produced small (1 mm diameter) turbid plaques on the 'cured' derivative RS602.

Although attempts to perform generalised transduction with this bacteriophage (designated Rφ6P) were unsuccessful, when recipient cells (RS602) were grown in aerobic conditions at 32 °C and at a multiplicity of infection of 1.0, 50% of 'survivors' of bacteriophage infection were penicillin resistant. An analysis of 100 penicillin resistant transductants derived from this experiment showed that each produced a diffusible penicillinase

The question now arises as to the exact nature of this high frequency transduction; at least two explanations seem possible Either the transduction is mediated by a defective specialised transducing bacteriophage analogous to PIIde in *Staphylococcus aureus*[10], or the wild type bacteriophage

Table 1 The relationship between penicillin resistance and lysogenisation by Rφ6P in *R sphaeroides*

Possible phenotypes	Number of colonies
$\mathrm{Pen^s}\,\varphi^-$	1127
$\mathrm{Pen^s}\,\varphi^{+}$	0
$\mathrm{Pen^r}\,\varphi^-$	0
$\mathrm{Pen^r}\,\varphi^+$	123

An exponential culture (about 5 × 10^8 colony forming units per ml) of RS602 (penicillin-sensitive, Rφ6P sensitive) grown with aeration at 32 °C, was infected with Rφ6P at a multiplicity of 0.1 The bacteriophage were allowed to adsorb for 30 min at 32 °C without aeration and then excess free bacteriophage were removed with anti-bacteriophage antiserum. The bacteriophage infected cells were diluted and plated on PYEA (0.3% peptone, 0 3% yeast extract, 1.5% agar) to give approximately 50 colonies per plate. After 2 d of incubation at 32 °C the colonies were patched on to PYEA plates and later replicated onto PYEA + 1 μg ml^{-1} penicillin to determine their resistance/sensitivity phenotype. Lysogeny, as determined by release of free bacteriophage, was assayed by overlaying the patch plates with soft PYEA (0.8% agar) seeded with RS602 carries a gene for penicillinase production. In experimental conditions which limit infection to a single bacteriophage per cell, there was a 100% correlation between the presence of wild type bacteriophage and production of penicillinase (Table 1). Hence the penicillinase gene is probably carried as part of a wild type bacteriophage genome.

In view of the importance of plasmid coded penicillinase activity we explored the possibility that Rφ6P exists as a plasmid in the lysogenic cell. A simple test used to differentiate plasmid and chromosal genes is the Arber experiment[11]. Low level ultraviolet irradiation of transducing bacteriophage lysates stimulates transduction of chromosomal genes and depresses transduction of plasmid genes. Figure 1 shows a depressed frequency of transduction following irradiation, indicative of an extrachromosomal location for this gene in the transduced (lysogenic) cell. Confirmation on these data is being sought by the isolation and characterisation of plasmid DNAs from lysogenic (Rφ6P+) and non-lysogenic (Rφ6P−) derivatives of *R. sphaeroides*.

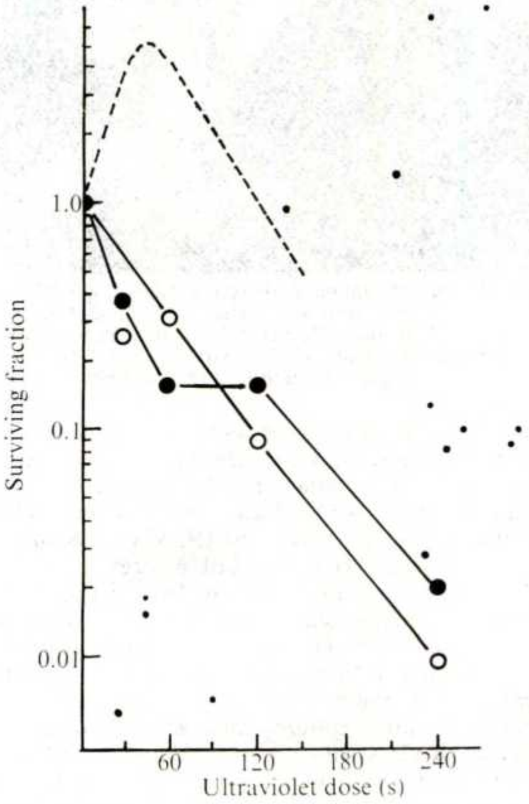

Fig. 1 The effect of ultraviolet-irradiation on the transduction of the penicillinase gene by Rφ6P. Bacteriophage Rφ6P was diluted in bacteriophage buffer (ref. 3 to give 10^9 plaque-forming units per ml and was ultraviolet irradiated for various lengths of time. Plaque forming titre (○) and transducing titre for the penicillinase gene (●) were determined for each dose of ultraviolet irradiation. The broken curve illustrates the effect of ultraviolet radiation on transduction of chromosomal markers in *Escherichia coli* (ref. 11).

It is unlikely that transforming DNA or gene-transfer-agents are involved in this process because transfer is insensitive to DNAase; inactivated by anti-Rφ6P antisera; and the vector has a molecular weight consistent with the purified bacteriophage particle. An electronmicrograph of the Rφ6P particle (Fig. 2) shows an isometric head 65 nm in diameter with a long flexuous non-contractile tail 12 nm × 250 nm, 2–4 tail fibres and no prominent tail plate. DNA molecules obtained from the bacteriophage by phenol extraction[12] and prepared for electron microscopy by the Kleinschmidt technique[13,14], show a majority of supercoiled molecules suggesting the encapsidated viral genome is circular. Using a variety of means such as DNase, freezing and thawing, alkali and heat treatment, the supercoils could be 'relaxed' to give open circles having a molecular length of $16.5\pm1.0\ \mu m$ which corresponds to a molecular mass of $33\pm2\times10^6$ (ref. 15). The only other report of a bacteriophage which possesses a closed circular, supercoiled, extracellular genome is PM2, a bacteriophage whose natural host is a marine pseudomonad[16].

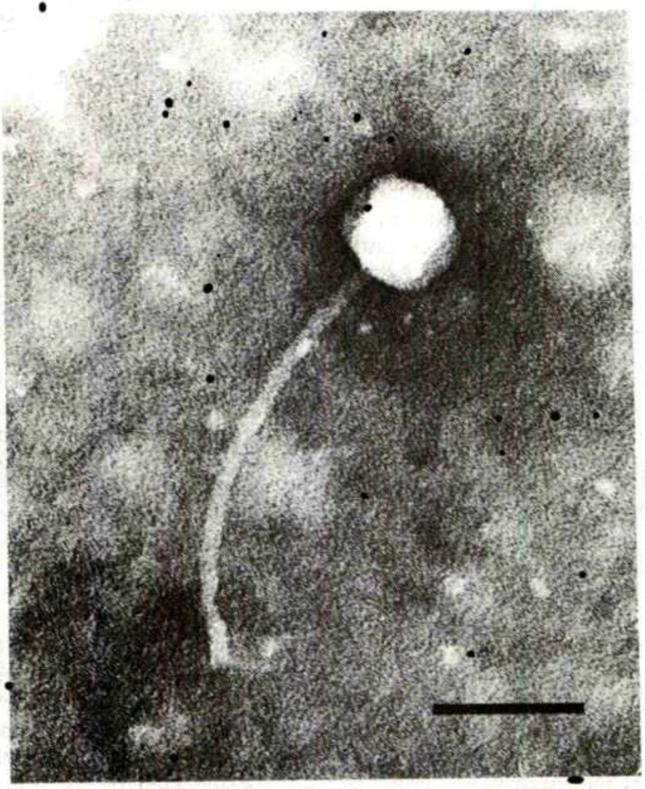

Fig. 2 Bacteriophage Rφ6P negatively contrasted with ammonium molybdate 1.0% (*p*H 6.0) using the procedure of Miller, Pemberton and Richards[17]. The bar represents 100 nm.

Richmond[7] states that "purely on statistical grounds bacteriophage conversion and restricted transduction are more likely to play some part in the spread of antibiotic resistance markers than is generalised transduction". This paper records the first instance of naturally occurring phage conversion involving an antibiotic resistance gene. If such virus-R plasmid combinations are widespread in nature then antibiotic therapy directed against drug resistant bacteria may be ineffective in removing the extracellular form of the plasmid from the environment. Finally, R-plasmids possess genes whose functions are still unknown; is it possible that some of these genes encode viral functions?

Early presence of ribonucleoprotein antigen on surface of influenza virus-infected cells

HOST defence against influenza A virus in experimental animals seems to be mediated mainly by antibody[1,2]. The mechanism by which antibody protects the host, however, is unknown. Antibody may either neutralise viral particles or recognise viral antigens at the surface of infected cells and then act at an early stage of infection, before viral replication is completed. The latter mechanism is theoretically more efficient, but might cause immunopathological destruction of the infected cells with harmful consequences. Viral envelope antigens (haemagglutinin and neuraminidase) have been shown to be present at the surface of influenza virus-infected cells, by haemadsorption[3], electron microscopy[4] and immunofluorescence[5]. Two main type-specific internal antigens have been described in influenza A virus—the matrix protein (MP) antigen[6] and the ribonucleoprotein (NP) antigen[7], a non-glycosylated polypeptide with a molecular weight of 58,000 (ref. 8). Immunofluorescence studies on fixed cells have shown that NP antigen is first demonstrable in the cell nucleus and then appears as granular masses within the cytoplasm, which become prominent at the cell borders later in infection, suggesting a close association with the cell membrane[9]. We report here that NP antigen can be detected by immunofluorescence as early as 2 h after the infection on the surface of unfixed mouse cells infected with influenza A virus.

Two methods were used to obtain anti-NP antibodies. The first is described in Table 1. A pool of sera was collected from CBA mice infected intranasally 3 weeks previously with a sublethal dose of an egg-grown A/PR/8 virus. After two cycles of absorption with the homologous concentrated A/PR/8 virus, no detectable antibodies to external components of the virus could be found in this serum, as shown by its negativity in single-radial-diffusion test (SRDT) immunoplates containing intact A/PR/8 virus particles as antigen. The zone area obtained in a SRDT immunoplate containing a disrupted influenza A avian virus (external antigens unrelated to those of A/PR/8 virus), however, was only slightly decreased. Thus, antibodies to internal components of all influenza A viruses were detectable in the serum before and after absorption. At low concentrations of disrupted avian influenza A antigens, the SRDT method reveals exclusively anti-MP antibodies when an anti-human influenza A serum is tested[10]. Comparison of results in SRDT with high and low concentrations of avian influenza A antigens indicated that anti-NP, but not anti-MP antibodies, were detectable in this serum. The second method to obtain anti-NP antiserum from rabbits immunised with NP antigen isolated after electrophoresis of influenza A/Hong-Kong/68 (H3N2) on cellulose acetate paper strips has been described before[11].

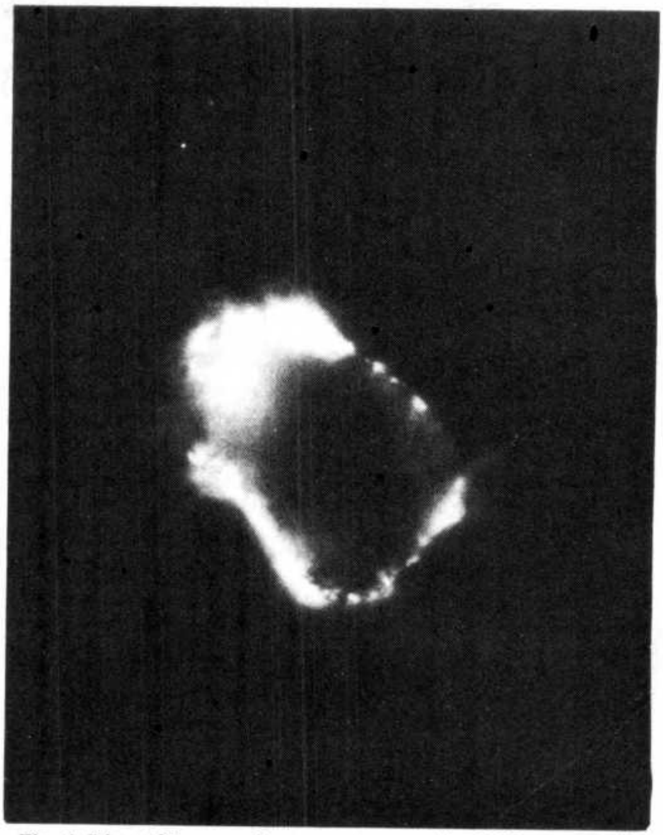

Fig. 1 Ring of immunofluorescence around a D55 mouse cell infected 3 h previously with influenza A/turkey/England/63 and treated with an anti-influenza A NP antigen (mouse anti-A/PR/8 serum absorbed with A/PR/8 particles) and FITC conjugated goat anti-mouse immunoglobulins.

For indirect surface immunofluorescence, unfixed, infected D55 mouse cells adherent on glass coverslips were treated as described in Table 2. Uninfected cells or infected cells incubated with fluorescein isothiocyanate (FITC) conjugated anti-immunoglobulins sera alone were negative. Similarly, control cultures infected with B/Lee virus (an influenza B virus with no cross reactivity with external or internal components of influenza A viruses) were negative.

Table 1 Specificity of anti-influenza antibodies in a mouse convalescent anti-A/PR/8 serum after absorption with A/PR/8 virus

Antigen in SRDT immunoplate*	Specificity of antibodies detectable with immunoplate	Zone area before absorption (mm²)	Zone area after absorption with A/PR/8 virus† (mm²)
Purified-concentrated A/PR/8 virus (15 mg ml⁻¹ in agar)	Anti-external antigens (haemagglutinin + neuraminidase)	[illegible].0	0
Purified-concentrated and SSS detergent disrupted avian N virus (1.5 mg ml⁻¹ in agar)	Anti-internal antigens (NP + MP)	10.7	8.8
Purified-concentrated and SSS detergent disrupted avian N virus (0.15 mg ml⁻¹ in agar)	Anti-MP	0	0

*A/PR/8 antigens were intact whole particles. The A/chicken/N/Germany/49 (Hav 2 Neq 1) was disrupted by mixing with equal volume of 1% sodium-sarkosyl sulphate (SSS) for 5 min before being mixed with 3 ml of agar.

†Equal volumes of anti-PR8 serum and of a purified-concentrated suspension of A/PR/8 virus (10 mg viral proteins per ml) were incubated for 1 h at 4 °C and centrifugated at 100,000g for 1 h. This procedure was repeated twice. The final supernatant was absorbed twice with packed chicken erythrocytes and heated at 56 °C for 1 h to remove all remaining viral particles. At the end of the process, an haemagglutination test was negative ($<\frac{1}{2}$).

Table 2 Surface immunofluorescence detected by anti-NP antibodies in mouse cells infected with influenza virus

Infecting virus	Mouse anti-A/PR/8 serum absorbed by A/PR/8 virus			Rabbit anti-NP serum			Haemadsorption			
	2 h	3 h	4 h	2 h	3 h	4 h	2 h	3 h	4 h	12 h
B/Lee	0	0	0	0	0	0	0	0	*	***
A/PR/8	0	0	*	0	0	*	0	0	0	*
A/Turkey/Eng.	*	***	**	*	***	**	0	0	*	***

Non-confluent monolayers of cells from the D55 mouse permanent cell line adherent on glass coverslips were infected with influenza B/Lee, A/PR/8/34 (HONI) or A/Turkey/England/63 (Hav 1 Nav 2) at about 100×ID50 per cell. At various intervals after infection the coverslips were washed thoroughly in cold phosphate-buffered saline (PBS). The cells were not fixed. After 30 min incubation at 4 °C with either inactivated mouse anti-A/PR/8 serum absorbed with A/PR/8 virus (see Table 1) or a rabbit serum anti-purified NP from A/Hong-Kong/68, the cultures were incubated for a further 30 min with (respectively) FITC-conjugated goat anti-mouse immunoglobulins serum or swine serum anti-rabbit immunoglobulins. After 1 h washing in cold PBS, they were mounted on glass slides with 50% glycerol phosphate. Surface immunofluorescence was recorded as absent (0), slight (*) intense (**) or very intense (***). Haemadsorption was performed by adding a suspension of 1% chicken erythrocytes for 30 min at 4 °C followed by washings in PBS.

This was not due to lack of production of influenza B antigens since B/Lee infected cells were able to haemadsorb chicken erythrocytes as early as 4 h after infection, and gave an intense haemadsorption 12 h after infection. A bright, 'patchy' immunofluorescence was found all over the surface of cells infected with either A/PR/8 or A/turkey virus (Fig. 1). This immunofluorescence was detected as early as 2 h after infection in A/turkey infected cells, increased rapidly and was maximal 3 h after infection, when the pattern was a complete ring of fluorescence around the cells. There was no evidence of capping. The fluorescence began to fade 4 h after infection, when the first haemagglutinins were appearing on the surface as shown by the slight positivity of the haemadsorption test at that time. The fluorescence was weaker and appeared later in A/PR/8 than in A/turkey infected cells. The negativity of haemadsorption at 4 h, and the modest positivity of haemadsorption found at 12 h suggest that A/PR/8 virus was poorly infective in D55 cells; this could explain the more discrete immunofluorescence found in these cells. Surface immunofluorescence was also detected with a rabbit anti-NP antiserum in primary kidney cells, Vero cells and MDBK cells infected with influenza A/FPV, A/NWS and A/HK/1/68 virus.

Our results strongly suggest that NP antigen is present on the surface of cells infected *in vitro* with influenza A virus. Thus two anti-NP sera gave a fluorescence on unfixed cells infected with an avian virus with external antigens unrelated to those of the viruses used to raise the antisera. But, two more internal structural polypeptides have been described in influenza A virus, P1 and P2 (ref. 8). The possibility that P1 and P2 may be present as minor contaminants of the NP antigen as separated on cellulose acetate strips cannot be excluded. At present, there is no way to detect selectively anti-P1 or P2 antibodies. The presence of such antibodies in our convalescent mouse anti-influenza serum, however, seems unlikely. Finally, non-structural antigens induced by influenza A virus have been detected by immunofluorescence in nucleoli of infected cells[12], and two non-structural viral polypeptides have been described[13]. If we fixed our cells with acetone, however, NP antigen was detected in the nuclear and paranuclear area of the cells, but there was no immunofluorescence in the nucleoli. The presence of antigens related to the virus core on the cell surface is not confined to influenza virus, since analogous observations have been made with oncornaviruses[14]. Presence of these antigens early in infection may facilitate assembly with the envelope antigens which enter in the membrane later. Pulse labelling studies with ^{35}S-methionine have demonstrated the early synthesis of the NP polypeptide in chicken embryo fibroblast cells infected with fowl plague virus and the association of this protein with membrane fractions of the infected cell[15]. The relevance to host defence mechanisms of our finding that NP antigen is present at an early stage on the surface of influenza virus-infected cells is not known. In theory, this would allow antibody or lymphocytes with anti-NP specificity to destroy infected cells at a stage when the virus has not yet replicated. Since all influenza A viruses share the same NP antigens, such a protective mechanism might cross the subtype barrier. Indeed, our unpublished results, and other reports[16,17] suggest that cross protection can be found between influenza A viruses which do not cross react at the level of their external antigens. The presence of type-specific internal antigens on the surface of infected cells might explain these observations. However, we have so far been unable to protect mice or ferrets by immunisation with purified MP or NP antigens or by passive immunisation with anti-NP or anti-MP antibodies[11,18]. This failure may mean either that the presence of NP-antigen on the surface of infected cells is not relevant to host defence, or that our immunisation technique was not sufficient to elicit an efficient immune response. Indeed a failure to induce protection by passive transfer of anti-NP antibody cannot exclude the possibility that, under physiological conditions, lymphocytes, but not antibody, can recognise NP antigen on the cell surface and protect the host either by direct cytotoxicity or by lymphokine secretion. Further work is needed to determine whether internal viral antigens on the surface of infected cells can be responsible for the paradoxical heterotypic protection observed with influenza A virus.

Infectious DNA from a whitefly-transmitted virus of *Phaseolus vulgaris*

GOLDEN yellow mosaic (bean golden mosaic) is a widespread disease of *Phaseolus vulgaris* in tropical and subtropical America[1]. The disease causes serious yield losses in several countries where beans are an important dietary staple[2,3]. The causal agent, long presumed to be a virus, also infects *P. lunatus* and *Macroptilium lathyroides* in the American tropics[4,5]. The pathogen is transmitted in nature and in the laboratory by the whitefly *Bemisia tabaci* Genn., and is also mechanically transmissible from the sap of infected plants[3,5]. An unusually small (18-nm diameter) nucleoprotein particle has been purified from diseased plants[5,6], and shown conclusively to be the whitefly-transmitted virus causing the disease[5]. Electron microscopy of purified virus revealed predominately geminate aggregates of the 18-nm particles[5,6]. The virus must be aldehyde-fixed before negative staining because it is disruped by the heavy metal salts (ammonium molybdate, sodium phosphotungstate, or uranyl acetate) used as negative stains. Thus, it is not known whether the geminate aggregate is the infectious entity or an artefact of fixation[5]. Nonetheless, its unusually small size sets this virus apart from most other plant viruses. I describe here the extraction of infectious DNA from purified golden yellow mosaic virus (GYMV), a result that further separates this virus from other previously described plant viruses.

Highest yields of purified virus were obtained from the leaves of virus-infected plants (*P. vulgaris* 'Top Crop') harvested 12–14 d after inoculation. Purification attempts with diseased tissue collected 19 d after inoculation yielded about 20% as much virus as was obtained at 14 d. The purification procedure (see Fig. 1) effected a complete separation between the virus and phytoferritin, which was present in copious amounts in extracts of GYMV-infected plants. Partially purified virus subjected to rate-zonal centrifugation in linear sucrose density gradients sedimented as a single band (Fig. 1).

The virus collected from density gradients was concentrated by ultracentrifugation and resuspended in 0.1 M sodium phosphate, *p*H 7.8, for analytical ultracentrifugation. Sedimentation velocity experiments showed a single sedimenting boundary (Fig. 2) with a mean sedimentation coefficient[7] ($S_{20,w}$) of 69.4±1.15. Attempts to determine the buoyant density of the intact virus in caesium chloride failed because the virus was disrupted by the salt.

Nucleic acid from GYMV was prepared by dissociating virus with 20 mM Tris-HCl, 5 mM sodium EDTA, *p*H 9.0, containing 2% (w/v) sodium dodecyl sulphate at 20° for 30 min (ref. 8). Dodecyl sulphate was precipitated by adjusting the mixture to 0.04 M KCl and storing it overnight at 4°. Nucleic acid was recovered from the supernatant liquid after low-speed centrifugation and dialysed overnight against 15 mM sodium citrate, 0.15 M sodium chloride (SSC), *p*H 7.0. Infectivity was tested by adding a small amount of carborundum to the nucleic acid in SSC and rubbing the mixture on expanding primary leaves of Top Crop beans with a sterilised ground glass spatula. Five days after inoculation typical symptoms of golden yellow mosaic appeared. Plants so inoculated were frozen and homogenised as before, and virus particles with the properties of GYMV (ref. 5) were obtained.

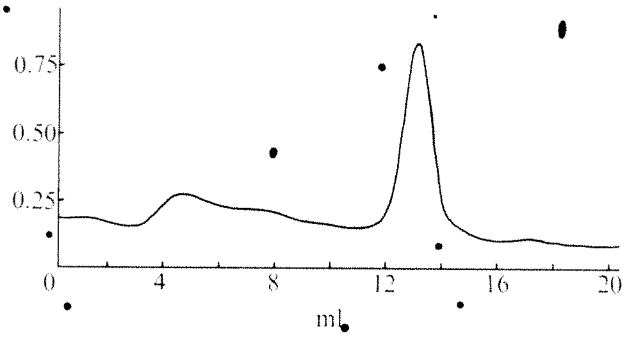

Fig. 1 Rate-zonal sedimentation profile of purified GYMV in linear 10–40% sucrose gradients. Leaves from infected plants harvested 12–14 d after inoculation were frozen on dry ice, crushed to a coarse powder and homogenised at 4 °C in 0.1 M sodium phosphate, 10 mM EDTA, 1 mM cysteine, *p*H 7.8 (3 ml buffer per g tissue). The homogenate was strained, clarified by centrifugation, adjusted to 0.2 M sodium chloride, and 4 g polyethylene glycol (Carbowax 6000, Union Carbide) was added per 100 ml clarified extract. The polyethylene glycol precipitate was collected by centrifugation after stirring for 2 h at 4 °C, and the virus dissolved from the precipitate in a small volume of 0.1 M sodium phosphate, *p*H 7.8. The virus was further purified by two cycles of differential centrifugation (12,000 r.p.m., 20 min, Sorvall SS-34 rotor followed by 27,000 r.p.m., 3.5 h, Beckman type 30 rotor) and then by rate-zonal centrifugation on linear sucrose density gradients (25,000 r.p.m., 4 h, Beckman SW 27.1 rotor). The sedimentation profile shown was obtained by scanning the sucrose density gradient from the top with an ISCO density gradient fractionator coupled to a Model UA-2 ultraviolet analyser.

The nucleic acid of GYMV sedimented in rate-zonal sucrose density gradients and the analytical ultracentrifuge as a single component (approximately 16S) but did not enter 2.5% polyacrylamide gels. Diphenylamine[9] and orcinol[10] tests were both positive, indicating that the nucleic acid of GYMV might be DNA. This interpretation was confirmed by nuclease sensitivity tests. Nucleic acid treated with bovine pancreatic DNase I (Worthington) was hydrolysed to oligonucleotides, whereas the nucleic acid was unaffected by treatment with RNase A (Sigma) (Fig. 3). The nucleic acid was unaffected by incubation for 4 h at 37 °C with 0.3 N sodium hydroxide, a treatment that hydrolyses RNA.

Only four other plant pathogenic viruses have been reported to contain DNA, and GYMV differs from each of these in several important respects. Cauliflower mosaic[11], dahlia mosaic[12] and carnation etch ring viruses[13] are aphid transmitted and have icosahedral particles of approximately 45 nm diameter. Cauliflower mosaic virus contains double-stranded DNA with a small amount of RNA covalently attached[14]. Potato leaf roll virus, which recent evidence suggests may

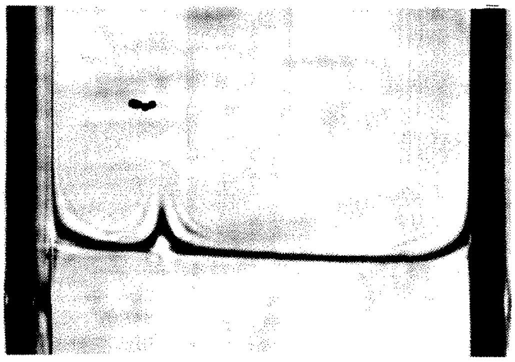

Fig. 2 Analytical ultracentrifuge Schlieren pattern of GYMV. Virus was adjusted to 0.5 absorption units (260 nm) in 0.1 M sodium phosphate, *p*H 7.8, and centrifuged in an An-D rotor at 35,660 r.p.m. Sedimentation is from the left. Photograph was taken 8 min after rotor reached full speed.

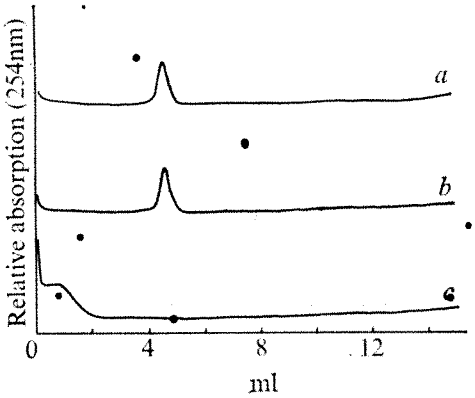

Fig. 3 Rate-zonal sedimentation profiles of GYMV nucleic acid in 10–40% linear sucrose density gradients following various treatments. Nucleic acid prepared in SSC, *p*H 7.0, as described in the text was adjusted to *p*H 5.0 and 5 mM Mg^{2+} by addition of 0.1 M sodium acetate, 50 mM magnesium sulphate, *p*H 5.0. Nucleic acid concentrations were adjusted to 10 μg ml^{-1}. To 0.5 ml portions were added 1 μl of *a*, water, *b*, RNase A (2.0 mg enzyme per ml), or *c*, DNase I (0.6 mg enzyme per ml water). Mixtures were incubated 4 h at 37 °C and then layered on sucrose gradients in 9/16 × 4 inch cellulose nitrate tubes and ultracentrifuged for 16 h at 25,000 r.p.m. in a Beckman SW 27.1 rotor. Profiles were obtained as in Fig. 1.

contain double-stranded DNA[15], is also aphid transmitted, and has particles 24 nm in diameter.

GYMV, the only whitefly-transmitted virus so far purified in sufficient quantity for characterisation, is superficially similar to several other viruses or virus-like particles of plants or fungi[16–18]. But there are as yet no reports on the nature of the genome of any of these particles. In size and nucleic acid type, GYMV most closely resembles the parvoviruses, small icosahedral viruses of animals that contain a single-stranded DNA genome[19–21]. Preliminary studies (unpublished) suggest that the DNA of GYMV may also be single-stranded. Thus GYMV and perhaps other whitefly-transmitted viruses may represent an entirely new class of plant pathogenic viruses.

Biochemical characterisation of a serum thymic factor

THE search for biologically active peptides with hormonal properties has been intense. The thymus has been looked upon as a source of such materials by a number of investigators but so far no generally accepted compounds have emerged[1–5]. We present here a sequence for a nonapeptide which is found in the serum of several animal species, where its presence is thymus-dependent[6–8].

For some years we have been attempting to isolate and characterise this material, which we call FTS (*facteur thymique serique*) from the serum of various mammalian species[6–8] in particular the pig[8]; the procedure for extraction has been described in detail elsewhere[9]. Briefly, it consists of dialysis and Sephadex column purification, the stages of which are associated with a progressive increase in biological activity. This has been monitored chiefly by quantification of the effect of the extract on a rosette assay. There is a general correlation between results obtained with this method and with more obviously immunological restoration procedures (refs 9–13). The rosette assay is quick, reproducible[14,15] and amenable to a large-scale testing programme in spite of its somewhat esoteric nature.

Defibrinated pig blood (2,000 l) was ultrafiltered through polyacrylonitrile membranes, concentrated on an Amicon UM2 membrane and subjected to gel filtration on Sephadex G-25 (0.2 M phosphate buffer, *p*H 7.3). The active fractions were chromatographed on carboxymethyl cellulose (CMC) (0.02 M phosphate buffer, *p*H 6.3) and eluted with a NaCl gradient in a single peak at 0.12 M NaCl (Figs 1 and 2). Active fractions (1:4 × 10^7) were lyophilised and subjected to gel filtration on Sephadex G-25 packed in 5% acetic acid, and then on Sephadex G-10 in distilled water. The assay of biological activity used at each stage of purification[10,16] is based on the capacity of thymic extracts to render spleen rosette-forming cells from adult thymectomised (Tx) mice sensitive to inhibition by anti-θ serum and azathioprine. The purity of FTS thus isolated was assessed by (1) the presence of a single spot in thin-layer chromatography (TLC) in five different systems; (2) reproducible stoichiometry of amino-acid composition: Asx, Ser_2, Glx_2, Lys, Gly_2 Ala; (3) the absence of detectable amounts of these amino acids in the control unhydrolysed sample. Sequence studies were performed by Edman's technique as modified by Gray[17], using dansylation for free amino group determination.

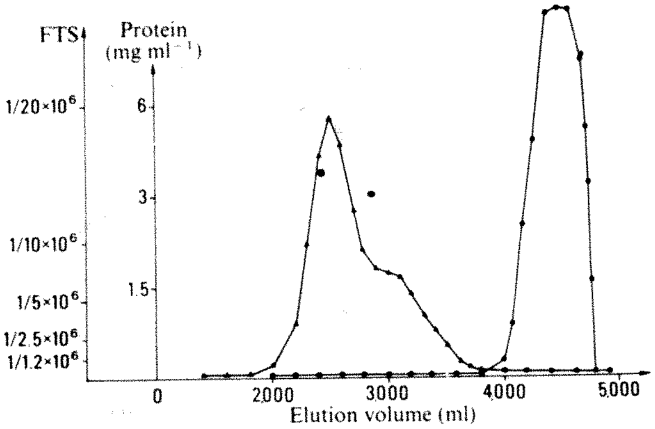

Fig. 1 Elution of pig serum ultrafiltrate on Sephadex G-25 (0.2 M phosphate buffer, *p*H 7.3). FTS activity was evaluated by the sheep cell rosette θ conversion assay. ▲, Proteins; ●, FTS.

As no NH_2 terminus could be identified in general, the sequence technique was applied to a tryptic digest with the following result: Ser–Glx–Gly–Gly–Ser. The COOH terminus, Asn, was evaluated, after treatment with carboxypeptides A, by dansylation. In one sample a faint glutamic acid spot was seen

Table 1 Principal biological activities of partially purified natural FTS

	Concentration dose	References
θ Conversion (Komuro and Boyse assay) *in vitro*	0.1 ng ml^{-1}	22
in vivo	15 ng per mouse	23
Enhancement of the generation of alloantigen reactive cytotoxic T-cells in Tx mice	15 ng weekly (per mouse)	13
Induction of suppressor T-cells in NZB mice assayed using antibody production against polyvinyl pyrrolidone	15 ng weekly (per mouse)	12
Enhancement of mitogen responses in nude mice (*in vitro*)	1 ng ml^{-1}	9
in adult Tx rats (*in vivo*)	75 ng (per rat)	24
Normalisation of the abnormally high level of autologous erythrocyte binding cells in adult Tx mice	15 ng (per mouse)	11

FTS was isolated on the basis of its action on the sheep cell rosette assay[8].

as the NH_2 terminal residue after dansylation; Edman degradation successively revealed Ala and Lys. The only amino-acid sequence compatible with all data reported above is:

Glx–Ala–Lys–Ser–Glx–Gly–Gly–Ser–Asn.

The amino group of residues 1 and 5 is still uncertain. It is likely, because of the difficulty of identifying free amino groups, that most of the NH_2 terminal residues are in the pyroglutamic form at the end of the isolation procedure (whether natively pyroglutamic acid or transformed *in vitro*). Such pyroglutamic acid, however, is apparently biologically active, for the blocked peptide is active in the rosette assay (as indicated by studies of biological material and confirmed by the activity of the synthetic peptide). Residue 5 is probably glutamine rather than glutamic acid in view of the isoelectric point of the peptide (7.3).

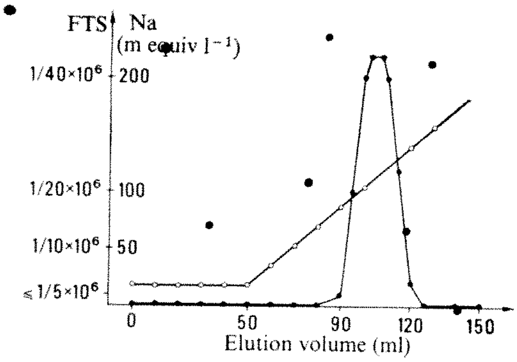

Fig. 2 Elution of Sephadex G-25 eluate after chromatography on CMC (0.02 M phosphate buffer, *p*H 6.3) and addition of NaCl. ●, FTS; ○, (Na+).

A peptide has been synthesised based on our sequence (with pyroglutamic acid as the NH_2 terminal residue) by the Merck peptide group (West Point, Pennsylvania) using Merrifield's technique of solid phase synthesis[18]. The synthetic peptide has been shown to behave like FTS on TLC (five systems) and had the same elution volume on Sephadex G-25 (0.2 M phosphate buffer, *p*H 7.3 and 5% acetic acid). Its biological activity was extremely high in the sheep cell rosette assay both *in vitro* and *in vivo*—of the same order of magnitude as natural FTS (Table 2).

In conclusion, we have presented direct evidence for the presence in normal blood of a thymus-dependent nonapeptide of molecular weight about 900, which adds to the list of biologically active peptides which could be hormones. The high activity of the synthetic peptide in the rosette assay of the peptide synthesised on the basis of the amino-acid sequence supports the specificity of its action. Its activity in various systems suggests that the natural peptide is involved in T-cell differentiation. These (Table 1) include (1) θ conversion *in vitro*[22] and *in vivo*[23]; (2) enhancement of the generation of alloantigen reactive cytotoxic T-cells in Tx mice[13]; (3) induction of suppressor T-cells in NZB mice assayed using antibody production against polyvinyl pyrrolidone[12]; (4) enhancement of mitogen response in nude mice *in vitro*[9] and ATx rats *in vivo*[24], and (5) normalisation of the abnormally high level of autologous erythrocyte-binding cells in ATx mice[11]. But the mechanism of such possible FTS involvement in T-cell differentiation is unclear. Most of the biological activities have been demonstrated in adult Tx and NZB mice which suggests that FTS effects the late stages of T-cell maturation. Too little is known to implicate FTS in the first stages of differentiation. It is possible that direct contact between T-cell precursors and thymic epithelium is then necessary whether or not it is mediated by humoral mediators. Alternatively, FTS may not be directly involved in T-cell differentiation in normal conditions and would be classified with previously described pharmacologically immunoactive peptides[19–20] which act in other systems. In any case, FTS might prove useful for the manipulation of T-cell subsets *in vivo*, particularly in clinical conditions showing subtle T-cell deficiency, probably involving the last stages of T-cell maturation, as is well documented in the spontaneously autoimmune NZB mice[21].

Table 2 Comparison of biological activities of natural and synthetic FTS

Sheep cell rosette θ conversion assay[8]	Natural FTS	Synthetic FTS
in vitro	$1–5\times10^{-2}$ pg ml^{-1} ($1–5\times10^{-14}$ M)	0.7×10^{-2} pg ml^{-1} (0.7×10^{-14} M)
in vivo	0.1 ng	0.1 ng
Autologous erythrocyte-binding cells[11]	0.2 ng	0.1 ng

Lymphocytes suppressing both immunoglobulin production and erythroid differentiation in hypogammaglobulinaemia

CELLS blocking immunoglobulin (Ig) synthesis *in vitro* have been found among gradient-isolated blood mononuclear cells of individuals with variable immunodeficiency[1–4], immunodeficiency with thymona[1,3,4], infantile X-linked immunodeficiency[4], multiple myeloma[5] and Hodgkin's disease[6]. It has been suggested that the suppressor cells block terminal differentiation of human B lymphocytes[7]. The association of red cell aplasia and immunodeficiency states is well documented[8]. A circulating Ig capable of interfering with red cell formation has been demonstrated in several persons[9,10]. The majority of individuals with these disorders, however, have no circulating inhibitor of erythropoiesis. In the present study, lymphocytes from two persons with immunodeficiency with thymoma, one of whom had repeated episodes of red cell agenesis, were cocultivated in assay systems in which human blood B lymphocytes and human bone marrow erythroid precursors differentiate *in vitro*. The results suggest that the 'suppressor' cells observed in certain immunodeficiency diseases may act on both lymphocytic and haematopoietic target cells.

Two patients (S1 and S2) diagnosed as having immunodeficiency with thymoma were studied. Ig values for S1 were: IgG, 180; IgM, 0; IgA, 15 mg%; for S2: IgG, 305; IgM, 23; IgA, 22 mg%. Both individuals have had spindle cell tumours of the thymus removed and are currently receiving intramuscular gammaglobulin. Patient S1 has had three episodes of red cell agenesis documented by a falling haematocrit, absent blood reticulocytes, and absent bone marrow erythroid precursors. Remission was induced with steroids which have been tapered to 5 mg prednisone daily. Patient S2 is haematologically normal. In a previous report[11], patient S1, referred to as B.D. lacked most surface Igs from her blood lymphocytes, whereas S2 (M.P.) was in the normal range.

Lymphocytes were isolated from sterile blood of patients S1, S2 and controls by defibrination over glass beads followed by centrifugation on a Ficoll–Hypaque gradient[12], and cultured on the same day. Phagocytic cells were removed by sedimentation over a plastic Petri dish for 60 min at 37 °C. T lymphocytes were isolated by rosette formation with sheep red cells as described previously[13].

Measurement of Ig synthesis *in vitro* has been described previously[3,14] (for experimental details, see Table 1). Erythropoiesis *in vitro* was studied by determining the effect of the patient's serum and mononuclear cells on erythropoiesis using the number of erythroid colonies formed by normal human erythroid precursor cells in response to erythropoietin (EP) in the plasma clot system[15] (for details, see Table 2).

Cultured S1 and S2 mononuclear cells produced much less Ig *in vitro* than cells of normals in similar conditions. In single cultivation experiments shown on the top three lines of Table 1, the means for Ig production of 19 experiments on 14 normal controls were compared with combined results of experiments with S1 and S2. Individual experiments, from which the data in Table 1 were derived, generally included one patient and 1–3 controls tested on the same day. In such individual experiments there was never overlap between the patient and controls; S1 or S2 always produced 30% or less Ig than controls.

Table 1 Effect of blood mononuclear cells on Ig production of PWM-activated human lymphocytes *in vitro*

	Lymphocyte donor†	No. of expts‡	Ig (k+λ) S§	P§
			c.p.m. (mean ± s.e.m.)	
Single cultivation*				
	N	19	236±29	337±31
	S1	7	6±2	13±5
	S2	4	10±5	40±24
Co-cultivation*				
	S1+N	14	23±8	53±10
	S1+N(ADH)‖	2	37	42
	S1(T)¶+N	2	43	10
	S2+N	3	47±12	129±111
	N+N	4	261	402

* In single cultivation experiments 4×10^6 isolated mononuclears were cultured for 7 d at a concentration of 2×10^6 cells ml^{-1} in RPMI 1640 containing 17% foetal calf serum, 1% PWM (Grand Island Biol. Co., Grand Island, New York); and penicillin, streptomycin, and glutamine as described[3,13]. At the end of the culture period the cells were washed, suspended in leucine-free MEM and permitted to incorporate ^{3}H-leucine (10 µCi per 10^6 cells) for 4 h. Ig was determined on Triton-X-solubilised cell pellets and spent culture fluid fractions by a two-stage antibody immunoprecipitation procedure[3]. The mixed antisera had specificity for both kappa and lambda light chains. Data expressed as c.p.m. per 10^6 lymphocytes are after subtraction of control tube. Only experiments in which the control was <35% of the experimental results were considered valid. Cocultivation experiments were carried out with 4×10^6 cells of each cocultivant at 2×10^6 cells ml^{-1}. Preliminary cocultivation experiments showed no difference in Ig production when the cell concentration was varied from 1 to 4×10^6 cells ml^{-1}.

† N refers to normal control donors of lymphocytes. S1 and S2 are patients having immunodeficiency with thymoma.

‡ In the single cultivation experiments 14 different normals were involved in the 19 experiments. In co-cultivation experiments S1+N involved 6 different combinations of co-cultivants: S2+N involved 3 different combinations and N+N involved 4 combinations.

§ S refers to the secreted Ig found in the culture fluid after radio-incorporation while P refers to the cell fraction.

‖ Adherent cells were removed by leaving isolated mononuclear cells in a shallow plastic Petri dish for 60 min at 37 °C, decanting the cells which remain suspended, and using them. Latex ingestion indicated less than 2% of the remaining cells were macrophages.

¶ S1(T) were T lymphocytes isolated by the sheep red cell rosette method.

PWM is pokeweed mitogen.

Cocultivation experiments between S1 and S2 and normals demonstrated that both S1 and S2 blocked Ig production by cultured normal B lymphocytes. If the data are calculated as Ig c.p.m. as a percentage observed/expected (expected = 1/2 c.p.m. of normal + 1/2 c.p.m. of S1 or S2 in single cultivation), S1 is <20%; S2 is <40%. When normals were cocultivated together the observed/expected Ig production was close to 100% of the observed/expected.

Results for secreted and cellular Ig fractions in Table 1 were comparable, suggesting that the defect was not a failure to secrete but rather an inability to synthesise Ig. S1 quantitatively had greater suppressor activity than S2 in single cultivation and cocultivation studies.

Table 2 shows data for the plasma clot erythroid colony testing. In the absence of EP (lines 1–4 of Table 2) no erythroid colonies were formed from bone marrow or lymphoid elements. When EP was added, as seen in line five of Table 2, several hundred colonies were observed. Serum from S1 or S2 did not significantly alter the number of erythroid colonies observed (data not shown). Mononuclear cells from normal subjects enhanced the number of erythroid colonies: the differences noted were significant: the figure in line 6 is the mean of 28 experiments. When 1×10^5 lymphocytes from the putative suppressor cells, S1 and S2,

‖ T lymphocytes isolated by sheep red cell rosette method[13].

BMC, Blood monocuclear cells.

Adh, Adherent.

Bone marrow cells obtained from haematologically normal individuals by aspiration from the posterior superior iliac crest were cultured in the presence or absence of 2 IU EP as follows. Each marrow (6×10^5 cells) was cultured with media containing either normal human or patient serum (0.05, 9.1 and 0.2 ml per culture), normal human lymphocytes or patient's lymphocytes (0.5, 1, 2, 4 and 6×10^5 lymphocytes per 6×10^5 marrow cells). The cultures were carried out for 5–7 d at 37 °C in a humidified atmosphere of 5% CO_2 in air. Only colonies composed of 8 or more erythroid cells were considered in the tabulation of the results.

were added, there was significant decrease in the number of colonies. The degree of suppression is greater for S1 than for S2. Hydrocortisone (lines 9 and 10, Table 2) did not affect the suppression phenomenon.

When adherent cells were removed from S1 and S2 mononuclear cell populations (Tables 1 and 2) there was no loss of suppression in either the Ig production or plasma clot system. Isolated T cells could suppress cocultivated cells in both systems, suggesting that the suppressor cell(s) was a T lymphocyte.

The data demonstrate that lymphoid cells which interfere with the maturation of both human erythroid precursors and of B lymphocytes in culture are present in the blood of two persons with immunodeficiency with thymoma. By contrast, cells from healthy controls stimulate the production of erythrocytes in the plasma clot system and leave Ig production essentially unaffected in the PWM-activated Ig production assay.

T lymphocytes and adherent cells, which suppress Ig production *in vitro*, are present in a number of immunodeficiency diseases[1-7]. Caution must be exercised in interpreting these cells as aetiologic in view of recent data which show that suppressor T lymphocytes are part of the normal immunoregulatory elements in the immune response[16]; suppressor cells are induced by lectins and other agents[17]; and suppressor cells are found in the genetically determined disorder, infantile X-linked immunodeficiency[4], in which an inherited defect determining suppressor cells would be less likely than the presence of such cells as an epiphenomenon. In the present study, the observations that S1 possessed suppressor cells for erythroid cell development while in remission from her anaemia, and S2 had similar cells although haematologically normal, make it unlikely that these cells were the sole cause of the anaemia in S1.

Recent studies have focused on the role of 'suppressor' mononuclear cells in haematological disorders—particularly disorders in which there is arrest of bone marrow cells. Suppressor cells of erythropoiesis have been found in cases of Diamond–Blackfan syndrome using the plasma clot assay[18]. There are recent observations implicating blood mononuclear cells in selected cases of aplastic anaemia[19,20]. The present paper, however, is the first in which the same patient has been shown to have suppressor cells for both lymphoid and erythropoietic cells.

The lack of change in suppression after removal of adherent cells and its production by T cells is consistent with the suppressor cells being T lymphocytes in both *in vitro* assays. It is not known whether separate cell subpopulations are involved. Dissociation of suppression of Ig production from suppression of erythroid cell maturation has, however, been noted in cases of Blackfan–Diamond syndrome[18], and in primary immunodeficiency.

The difficulties in evaluating the relationship between 'suppressor' cells and disease states is complicated by the different types of cells which may possess suppressor activity, and the differences between *in vitro* and *in vivo* conditions. Nevertheless, the present data raise the possibility that suppressor lymphocytes play a role in the pathophysiology of diseases in which both lymphocytic and hematopoietic abnormalities coexist.

This work was supported in part by the Institute of Allergy and Infectious Diseases, the American Cancer Society, the National Cancer Institute and presented in part by Dr Zanjani at the American Society of Hematology Meeting in Dallas, Texas, April 1976.

Reduced rates of proteolysis in transformed cells

GROWTH of cells implies a net accumulation of intracellular proteins with the rate of protein synthesis exceeding the rate of protein degradation. It follows that the seemingly uncontrolled growth of transformed cells could be produced by a reduction in intracellular proteolysis without any concomitant increase in protein synthesis. In order to examine this hypothesis we have determined the rates of protein degradation in two pairs of (non-isogenic) cell types—non-growing rat liver hepatocytes and the chemically transformed Reuber H35 hepatoma, and mouse BALB/c 3T3 fibroblasts and 3T3 fibroblasts transformed with Simian Virus 40 (SV40). We have measured proteolysis over a wide range of insulin concentrations with cells incubated in either an enriched medium or a basal salts medium (step-down conditions). Insulin was chosen because it inhibits intracellular proteolysis in several cell types[1-6] and may have a major role in the normal regulation of proteolysis *in vivo*. We report here that transformed cells have a lower basal rate of proteolysis together with an increased sensitivity towards inhibition by insulin, two factors which will contribute to the rapid growth of such cells.

Cell proteins were labelled by a 16-h incubation with ^{3}H-leucine and protein degradation was followed after an intervening 3-h chase (Fig. 1). This chase period is desirable for the effective removal of unincorporated ^{3}H-leucine and essential to allow for the insulin-insensitive degradation of short-lived proteins[4,7]. Leucine (2 mM) was added during both the chase and degradation periods to reduce the specific activity of ^{3}H-leucine released from labelled proteins and thus suppress any reincorporation of isotope which would cause an apparent reduction in proteolysis.

We found substantial differences between hepatocytes and hepatoma cells in the overall rate and regulation of intracellular proteolysis (Fig. 1). Breakdown of 14% of the labelled hepatocyte proteins occurred during a 4-h incubation in salts medium. This rate is 50% greater than found for Reuber hepatoma cells labelled and incubated in identical conditions Furthermore, the lower rate of protein degradation in hepatoma cells also occurred when the experiment was performed in Eagle's Minimal Essential Medium (MEM)[9]. Insulin addition at the beginning of the degradation period inhibited intracellular protein degradation in both cell types, but was effective at much lower concentrations in the hepatoma. Indeed the insulin concentration for half maximum inhibition in Reuber hepatoma cells was approximately 10^{-12} M, over two orders of magnitude less than the concentration required for comparable inhibition of proteolysis in hepatocytes (Table 1). Moreover, across the whole range of insulin concentrations tested, and even at concentrations producing maximum inhibition of proteolysis, rates of protein degradation in the hepatoma cells were still half those found for hepatocytes.

The lower proteolytic rate and higher sensitivity of protein degradation to insulin in hepatoma cells may reflect a difference between growing and non-growing cells rather than a difference between transformed and normal cells. The omission of serum during the 3-h chase and 4-h degradation periods, however, would restrict growth of the hepatoma line, especially when incubated in a simple salts medium without amino acids. It seems more likely therefore that the differences in proteolytic rate between the two cell types reflect a changed genotype independent of cell growth rates.

This conclusion is supported by data obtained with mouse 3T3 and SV40-3T3 fibroblasts which differ by the insertion of viral genome[12,13]. Proteolysis measurements on these cell types show qualitatively similar results (Fig 2) to those described for hepatoma cells and hepatocytes. Thus control rates of protein degradation in nutritional step-down

Table 1 Insulin concentrations for half maximum inhibition of protein degradation

Cell type	Medium	
	Salts	MEM
Rat hepatocytes	7×10^{-10} M	1×10^{-9} M
Reuber H35 rat hepatoma	3×10^{-12} M	2×10^{-12} M
3T3 (BALB/c3T3) mouse fibroblasts	3×10^{-9} M	1×10^{-9} M
SV40 transformed 3T3	2×10^{-10} M	6×10^{-11} M

Values were calculated from the data in Figs 1 and 2.

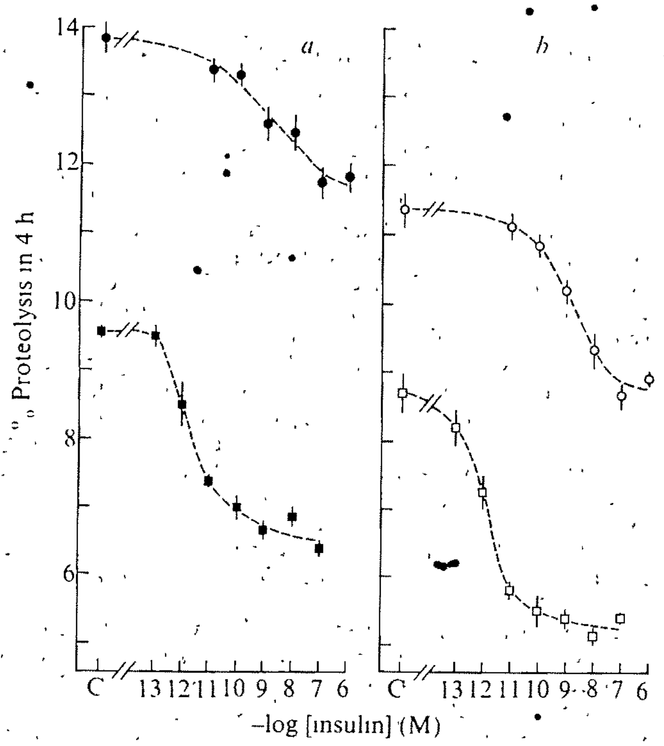

Fig. 1 Proteolysis in hepatocytes and Reuber H35 hepatoma cells. Livers from fed, 150-g rats were perfused with medium containing collagenase to disperse the tissue[8]. Cells were isolated by shaking the dispersed tissue in perfusion medium at 37 °C for 15 min, and filtration through nylon gauze. The cells were pelleted by centrifuging at 50*g* for 1 min, suspended in calcium-free Eagle's MEM[9] containing 25 mg gentamycin per 100 ml, and transferred to sterile centrifuge tubes. Aseptic techniques were then adopted for subsequent preparation and incubation steps with the isolated cells. The cell suspension was centrifuged as before, the supernatant discarded, and the cell pellet washed once in the same buffer A final suspension of approximately 10^8 parenchymal cells was transferred to 250 ml of MEM containing 20 mM N-Tris [hydroxymethyl]methyl-2-aminoethane sulphonic acid (TES) *p*H 7 5, 25 mg gentamycin, 25 mg streptomycin sulphate, 15 mg penicillin G, 2 5 mg fungizone and enriched with amino acids and vitamins at twice the recommended amount[9], together with 10% foetal calf serum (enriched MEM). Aliquots of 5 ml of this diluted cell suspension were dispensed into 60-mm plastic Petri dishes and transferred to a humidified incubator at 36.5 °C and gassed with 5% CO_2 in air Almost all the hepatocytes attached to the dishes and after 24 h the cells showed a marked morphological change from birefringent spherical cells to translucent flattened cells with clearly visible intercellular abutments. At this time the medium was changed to one with similar constituents but containing ^{3}H-leucine 1 μCi ml^{-1} (specific activity 50 Ci mmol^{-1}) and with non-radioactive leucine omitted. The cells were incubated in this medium for a further 16 h to label intracellular proteins The medium was then changed to MEM containing 20 mM TES and 2 mM leucine but without serum (chase MEM). After a further 3-h incubation the plated cells were washed twice with Earle's salts and incubated either in *a*, Earle's salts with 20 mM TES and 2 mM leucine added (chase salts) or in *b*, chase MEM Insulin (Actrapid, Novo) was added at the concentrations indicated. After 4 h the cells were collected in medium by scraping with a rubber policeman after addition of Triton X100 to a final concentration of 0.5%, then thoroughly mixed on a vortex mixer and protein was precipitated from 250-μl portions by the addition of trichloroacetic acid (TCA) to a final con centration of 20%. The TCA mixtures were kept for 1 h at 0 °C, centrifuged for 10 min at 2000*g* and the radioactivity in both TCA-soluble and TCA-insoluble fractions measured using NCS Solubilizer (Searle Nucleonics) in a toluene scintillation solution[10]. Proteolysis was expressed as the percentage of total radioactivity in the TCA-soluble fraction (amino acids) after subtracting the TCA-soluble counts at zero time. Reuber H35 hepatoma cells[11], were grown to a similar density to that obtained with hepatocytes. Subsequent procedures were as for hepatocytes. Values shown for hepatocytes (●, ○) and hepatoma cells (□, ■) are means ± s.e m. for data on between 6 and 10 dishes at each insulin concentration and for control incubations (C) in the absence of insulin.

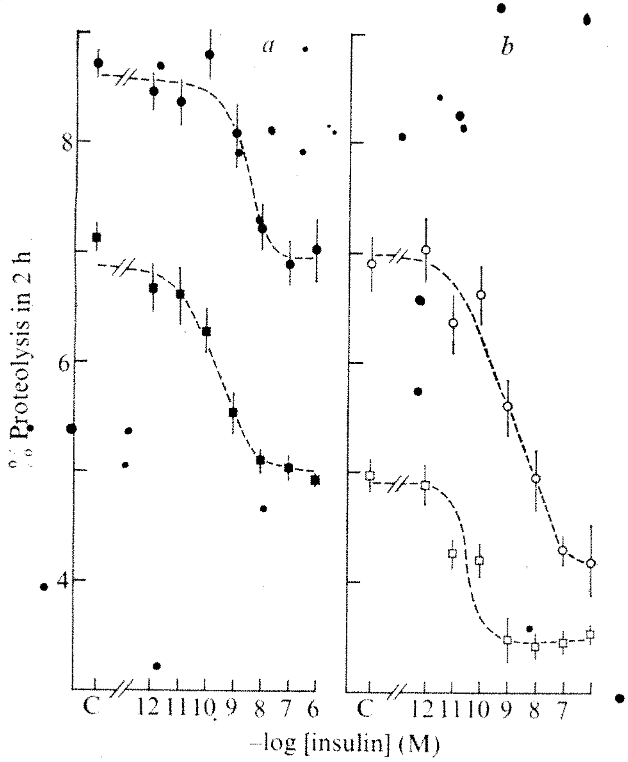

Fig. 2. Proteolysis in BALB/c 3T3 and SV40-3T3 cells. The cells were grown in enriched MEM. Labelling, chase conditions and washing were as described in Fig. 1, except for the omission of foetal calf serum during the labelling period. Collecting and radioactivity measurements in cell protein, medium protein, cell amino acids and medium amino acids were as described before[5,10]. Proteolysis is expressed as the percentage of total radioactivity in the sum of the two amino acid fractions. Values shown for 3T3 cells (○, ●) and SV40 3T3 cells (□, ■) are means ± s.e.m. for data on 6–15 dishes at each insulin concentration and for control incubations (C) in the absence of insulin. *a*, incubation in chase salts; *b*, incubation in chase MEM.

conditions (salts) are 25% higher in 3T3 compared with SV40-3T3 cells. A slightly greater difference is found when the comparison is made between the two cell types incubated in MEM. Furthermore, proteolysis is more sensitve to inhibition by insulin in the transformed fibroblast than in 3T3 cells. Such differences (Table 1) are less than seen between hepatoma and hepatocytes, but there is still a 15-fold difference in the concentration of insulin required to inhibit protein degradation by 50%.

Lower basal rats of protein degeradation and higher sensitivity of the process to insulin inhibition will be important contributing factors towards rapid protein accumulation and growth of cancer cells. The lower basal rate of protein degradation in transformed cells might represent a partially inhibited condition. This is unlikely, however, since the extent of insulin inhibition in transformed cells is at least as great as found for normal cells. Rather, the difference in insulin sensitivity might be due to greater receptor affinity on the plasma membrane of transformed cells. Alternatively, a higher rate of insulin degradation in the non-cancer cells might account for the higher concentration of insulin required to inhibit protein degradation. But, this would occur only if the receptor affinity in the non-cancer cells was great enough to account for the half-maximal effects on degradation in the cancer cells. This does not seem to be the case since the apparent K_D for insulin binding in both hepatocytes[14] and fibroblasts[15] is lower (10^{-9} M) than needed to satisfy this restriction, and in good agreement with our calculation of the half-maximum effect of insulin on proteolysis in normal cells. Therefore we consider it most likely that transformed cells have a higher receptor affinity for insulin and that this largely determines their lower rates of protein degradation, although the mechanisms involved remain obscure.

We thank Dr R. W. Hanson of the Fels Research Institute for encouragement and for providing facilities for J.M.G. Dr Stuart A. Aaronson supplied BALB/c 3T3 and SV40-3T3 cells.

Thermogenic defect in pre-obese *ob*/*ob* mice

YOUNG genetically obese (*ob*/*ob*) mice develop obesity even when pair-fed to their lean littermates[1–3]. This is due to an unusually high metabolic efficiency, which we have suggested results from a reduction in the "maintenance increment" to the basal metabolic rate (BMR)[4]. Factors involved include the thermic effect of food and the thermogenic response to an environmental temperature below thermoneutrality. Part of the evidence supporting this suggestion comes from the observation that mature *ob*/*ob* mice, and at least two other strains of genetically obese rodent, are unable to maintain their body temperature when exposed to cold[5–7]. At 4 °C both the *ob*/*ob* mouse and the Zucker (*fa*/*fa*) rat rapidly die of hypothermia[5,7]. In the mouse, thermogenesis rather than heat conservation has been established as the cause of the thermoregulatory defect[5,7]. We now report that a defective response to cold is apparent in preweanling mice bearing the *ob*/*ob* genotype about 2 weeks before they can be identified as obese by visual inspection. From this a test based on the response to 4 °C has been developed for the identification of *ob*/*ob* mice at 17 d old.

Exploratory studies showed that 17 d was the earliest age at which preweanling 'normal' mice can maintain their body temperature when placed in a cold room (4 °C) for up to 90 min. This age was therefore taken as the base-line for comparison of the response to 4 °C of lean and 'pre-obese' animals. Litters were derived from lean parents heterozygous for the *ob* gene (*ob*/−) since the obese (*ob*/*ob*) female is infertile and the obese (*ob*/*ob*) male is too corpulent to mate. Mice were placed at 4 °C for up to 60 min and their rectal temperature was measured periodically. Each litter consisted of two groups: those in the larger group, although showing some change, could maintain their body temperature within the normal range; those in the smaller group exhibited a marked decrease and had a lower initial temperature. Temperature response curves of mice from nine litters are shown in Fig 1. Mice unable to maintain a normal temperature were marked for subsequent identification and all members of each litter were returned to their nest. Each animal was then examined at 28–30 d old, the earliest age at which obese individuals can be identified by visual inspection. In all litters the mice that had been marked were obese and those that were unmarked were lean. Clearly, 17-d-old mice with the *ob/ob* genotype are less able than normal mice to respond to the cold.

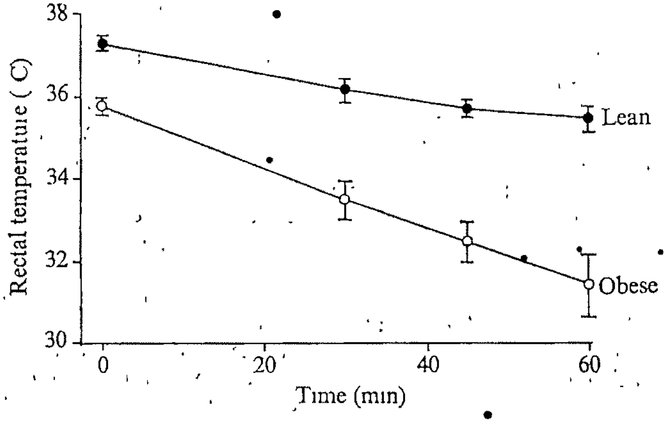

Fig. 1 Rectal temperatures of 17-d-old mice in response to an environmental temperature of 4 °C. Mice were removed from the nest and their initial temperature was taken by inserting a thermocouple (diameter <1 mm) 10 mm into the rectum; the thermocouple was attached to a Comark 3001 digital thermometer. Each mouse was individually caged and immediately transferred to a 4 °C room. Further temperature measurements were taken periodically. The results are expressed as the means ± s.e.m. for 39 lean animals (●), and for 16 animals that were subsequently found to carry the *ob/ob* genotype (○). At each time the temperature difference between the two groups was statistically significant, $P < 0.001$, on the basis of a Students' *t*-test.

More litters were then examined with the aim of using the impaired response to a 4 °C cold stress as a test for the *ob/ob* genotype. Such a test is essential if the metabolic changes preceding the development of obesity are to be elucidated. In total 133 mice from 19 litters were used. Before the experiment 7% were discarded as either abnormally small or in poor condition. The rest were categorised as 'definitely lean' or 'definitely obese' according to how they tolerated the cold. Some of those classified as definitely obese had such a precipitous fall in temperature that they had to be returned to the nest before the full 60-min test was completed. 19.5% of animals were predicted to be obese and 72.4% to be lean; the genotype of all these animals was found to be correctly predicted when they were examined for obesity at 28–30 d (Table 1). A few (8.1%) that could not be categorised readily were termed 'tentatively lean.' These showed a fall in temperature outside the normal range, but much less than for the 'definitely obese' mice. Of the 'tentatively lean' animals, two were found to be obese and eight to be lean. Clearly at 17 d-old, individuals that will be lean or obese can be obtained with certainty from litters derived from heterozygous parents. Genotype was predicted correctly for 98% of animals.

The stressfulness of the method of identification seems not to be a problem, for we have not observed an increased morbidity or mortality in cold-stressed mice, nor have we found long term effects on their growth rate and reproductive performance. Kaplan and Leveille[8] identified *ob/ob* mice between 18 and 20 d old by their reduced oxygen consumption at 25 °C. The main advantages of our procedure, apart from the marginal improvement in the age at which the genotype can be identified, are its simplicity and the ease with which many animals can be examined in a short time.

Table 1 Prediction of the genotype of lean and *ob/ob* mice aged 17 d by their response to an environmental temperature of 4 °C

Prediction		Result		%
Category	No	No. obese	No. lean	Correctly predicted
Definitely obese	24	24	0	100
Definitely lean	89	0	89	100
Tentatively lean	10	2	8	80

To investigate whether the thermoregulatory defect of *ob/ob* mice is detectable earlier than 17 d we examined the response to environmental temperatures less severe than 4 °C in mice aged between 12 and 17 d. Animals younger than 12 d could not be used because even our finest thermocouple probes caused rectal bleeding. With 12 d-old mice and an environmental temperature of between 15 and 20 °C *ob/ob* and lean animals were sharply differentiated. The former showed a marked fall in body temperature within 15 min of exposure to the cold (Fig. 2). The fact that defective thermoregulation occurs in *ob/ob* mice as young as 12 d indicates that a test similar to that for 17-d-old animals could be used for their identification.

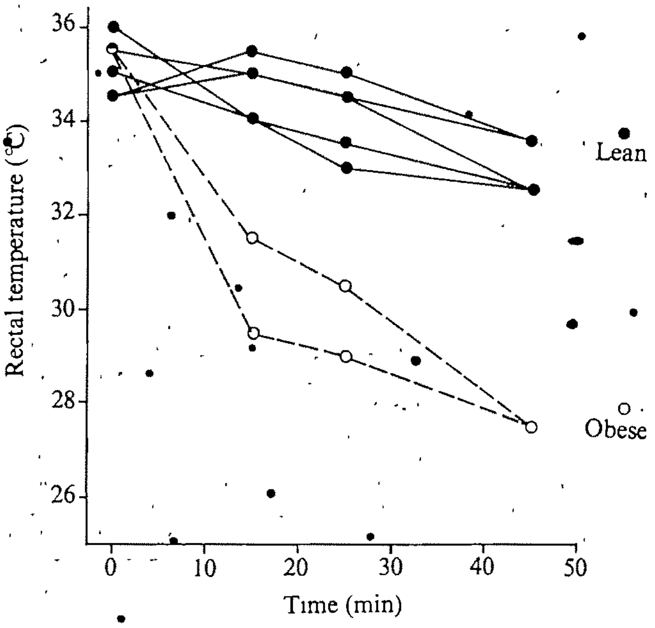

Fig. 2 Rectal temperatures of a litter of 12 d-old mice in response to an environmental temperature of 15 °C. Experimental details are the same as in Fig. 1. The animals fell into two groups, those subsequently found to be *ob/ob* (○) and those found to be lean (●).

The work reported here shows that the defective thermoregulation exhibited by mature *ob/ob* mice is not a secondary consequence of obesity. Because the defect in the adult animals is due to an impairment in the capacity for thermogenesis rather than in heat conservation[6,7], the same cause presumably applies to the defect in the pre-obese animals. These results therefore support the suggestion that a reduction in the "maintenance increment" of an animal's energy expenditure is a fundamental factor in the increased metabolic efficiency that leads to obesity[4]. In mice non-shivering thermogenesis is a major contributor to energy expenditure when the animals are maintained, as is usual, about 10 °C below their critical temperature. Thus, reduced non-shivering thermogenesis may account for the enhanced metabolic efficiency of *ob/ob* mice.

Post-weaning food restriction reduces adipose cellularity

KNITTLE and Hirsch[1] reported that varying the calorific intake of newborn rats by manipulating litter size during the 21-d suckling period followed by allowing free access to food after weaning caused the rats from small litters to have more adipocytes in the epididymal depot than rats from large litters. Hirsch and Han[2] reported that marked changes in depot size induced by starvation or experimental obesity produced no change in total number of adipocytes in the epididymal and retroperitoneal depots of rats even when these alterations occurred as early as 6 weeks of age. These and other studies[3–5] suggest that it is the calorific intake between birth and weaning rather than later in life that plays the important role in establishing the cellularity of the adipose tissue depots of the adult. But we report here data which indicate that a reduction in food intake can markedly influence the number of adipocytes in the depots of adults even when initiated as late as 6 weeks of age.

Barrier-bred SPF Fisher 344 rats (28 d old) (Charles River) were kept in a barrier facility. All rats were initially fed Ralston-Purina diet 5755. Body weight and food consumption were recorded for 2 weeks after which the diet allotment for half the rats was reduced over 1 week to 60% that of '*ad libitum* rats'. Rats on the restricted food intake received diet 5755-4 (Ralston Purina) which was identical to 5755 except the vitamin content was increased so that vitamin consumption was the same in both groups of rats. Thus of the 20 rats killed at 6 months of age, 10 were fed *ad libitum* for their entire life and the other 10 were kept on the restricted food intake from 6 weeks to 6 months of age.

At 6 weeks of age, the 10 rats to be fed *ad libitum* throughout their life ('*ad libitum* rats') averaged 93±2.7 g (s.e.m.) and the 10 rats to be fed a restricted amount of food from that time on ('restricted rats') averaged 96±5.7 g. At 6 months of age the *ad libitum* rats averaged 344±8.1 g and the restricted rats 212±4.2 g.

Table 1 Left epididymal and perirenal adipose depot masses in *ad libitum* and restricted rats

Adipose depot	Total depot mass (g)*		Depot mass (g) per total body mass (kg)*	
	Ad libitum rats	Restricted rats	*Ad libitum* rats	Restricted rats
Epididymal	5.0±0.25	1.7±0.16†	14.6±0.74	7.9±0.74†
Perirenal	5.1±0.21	1.5±0.17†	14.7±0.61	7.3±0.77†

Rats were killed by decapitation and perirenal and epididymal fat depots were removed and placed in 0.9% NaCl at 37 °C. Adipocyte size and cell number per depot were determined by a method modified from Stiles *et al.*[9], using type IV collagenase (Worthington lot 45M181X, 190 units mg^{-1}). Crystal violet was used to stain the nuclei of adipocytes, collagenase, stromal material and the small, more slowly floating cells were removed from adipocytes by allowing the latter to float to the surface of 15 ml digestion medium without collagenase. The infranatant was discarded and the washing of the adipocytes was repeated twice. This procedure did not influence the adipocyte size distribution when compared to the procedure of Stiles *et al.* which does not remove these contaminating materials before sizing the adipocytes.

*Data are means of 10 depots ± s.e.m.

†Significantly different from *ad libitum*-fed rats ($P<0.001$)

The restricted rats had smaller fat pads than did their *ad libitum* counterparts (Table 1). Furthermore, expression of these data as mass of depot per kg body mass showed that adipose tissue depots of the restricted animals contributed less to body mass than depots of *ad libitum* rats.

The mean diameter of the adipocytes in the epididymal or perirenal adipose depots of the restricted rats was smaller than that of the adipocytes from the *ad libitum* rats (Table 2). The total number of adipocytes in the left epididymal and perirenal fat depots of the restricted rats was markedly lower than the number in the fat depots of the *ad libitum* rats.

The pattern of development of adipose tissue in rats is well established[2,7,8]. From the time of weaning until approximately 14 weeks of age, the epididymal, retroperitoneal and subcutaneous depots grow by increases in both adipocyte size and number. At about the age of 14 weeks to at least 6 months of age the cell number is nearly fixed[2,6,10]. Similar patterns of adipose tissue development have been observed in many but not all species studied[1,11,12].

Table 2 Adipocyte size and number of adipocytes in left epididymal and perirenal adipose depots

	Ad libitum rats	Restricted rats
Adipocyte diameter (μm)*		
Epididymal	107±2.4	84±3.0†
Perirenal	114±2.6	86±4.0†
Adipocytes (× 10^6) per depot*		
Epididymal	7.4±0.38	4.6±0.19†
Perirenal	6.1±0.27	3.9±0.17†

*Data are means of 10 depots ± s.e.m.

†Significantly different from *ad libitum*-fed rats ($P<0.001$)

Although the number of adipocytes in the depots increases well past weaning, it is generally held that the number found in depots of the adult rat can be influenced by modifying calorific intake only if initiated in the preweaning period[1,5]. On the basis of the studies with rats and on data obtained with man, it has been suggested that the time between birth and 2 yr of age is critical for the development of human adipose tissue and in the pathogenesis of human obesity[13]. of human obesity[13].

Although calorific restriction of adults has not been shown to influence the number of adipocytes in their depots, some nutritional manipulations in adults do influence adipocyte number. High-fat diets increase the number of adipocytes in the depots when fed to adult rats in the presence of adequate amounts of B vitamins[14–16].

Our results show that the number of adipocytes in the depots of adult rats can be markedly reduced by food restriction initiated 2 weeks after weaning. The preweaning period is thus not the only period sensitive to reduction in food intake in regard to establishing adipocyte number in adult depots. How much later in childhood this nutritional regime can be initiated and still have a sizeable effect on adipose tissue cellularity is of great interest, but the design of our ageing research programme precluded obtaining such data. Whether food restriction initiated at 6 weeks of age leads to permanent reduction in adipocyte number (that is, one not reversed by *ad libitum* feeding), as is the case with preweaning restriction, was also not explored. It is possible that control of the development of adipose tissue cellularity may well be in the province of the paediatrician's work with schoolage children.

Proline analogue removes fibroblasts from cultured mixed cell populations

PRIMARY cultures of cells from various tissues have become important tools for many experimental studies, but attempts to prepare primary cultures of specialised cell types are frequently frustrated by the tendency of fibroblasts to grow more rapidly than other cells. During studies on procollagen biosynthesis by fibroblasts, it has been found that if the cells are incubated with any one of four proline analogues, the analogues are incorporated into protein and the incorporation of the analogues into procollagen polypeptides prevents the chains from folding into a triple helicial conformation[1-7]. We report here that if fibroblasts are grown in the presence of the proline analogue *cis*-hydroxyproline, their rate of growth is markedly limited. This may provide a simple technique for removing fibroblasts from cultures of mixed cell populations.

Fibroblasts isolated by controlled enzymatic digestion of the tendons of 17-d-old chick embryos, and primary cultures were prepared as described before[8]. Addition of 100 μg ml^{-1} of *cis*-hydroxyproline (*cis*-4-hydroxy-L-proline or allohydroxy-L-proline; Ajinomoto) to logphase cultures decreased the growth rate within 24 h (Fig. 1*a*) and thereafter the number of cells per flask decreased to less than the initial level. The same concentration of *cis*-hydroxyproline had no effect on the growth of KB cells (Fig. 1*b*), a cultured line of cells developed from a human epidermoid carcinoma. Also, it had no effect on the growth of a neuroblastoma cell line (Fig. 1*c*).

Examination of varying concentrations of *cis*-hydroxyproline (Fig. 2) demonstrated that the growth of primary cultures of tendon cells in late-log phase was inhibited with 50 μg ml^{-1} or more of *cis*-hydroxyproline. Cultures of mouse L-929 fibroblasts were more resistant and a concentration of 100-200 μg ml^{-1} was required to inhibit the growth. The growth of neuroblastoma or KB cells was not affected with 200 μg ml^{-1}, but there was partial inhibition with higher concentrations. The sensitivity to *cis*-hydroxyproline was not related in any simple manner to the rate of cell growth; in the experiments reported here the doubling time was 16 h for the primary cultures of tendon fibroblasts, 30 h for the L-929 fibroblasts, 24 h for the KB cells, and 24 h for the neuroblastoma cells (Fig. 1).

The selective effect of *cis*-hydroxyproline on fibroblasts was further illustrated by preparing mixed cultures of fibroblasts and KB cells, and then labelling the cultures with antibodies specific for prolyl hydroxylase[9], the enzyme which synthesises the hydroxyproline in procollagen. The antibody was conjugated with peroxidase and located in cells by reacting the peroxidase with 3,3′-diaminobenzidine[10] (Sigma). Figure 3*a* shows that fibroblasts were readily distinguished from KB cells in untreated cultures. In cultures treated with 100 μg ml^{-1} of *cis*-hydroxyproline for 7 d, KB cells were present but no fibroblasts were discernible either by morphology or a specific antibody stain for prolyl hydroxylase (Fig. 3*b*).

In a separate series of experiments, cultures in late log phase were incubated with ^{14}C-proline and then assayed for non-dialysable ^{14}C-hydroxyproline[8,11], as a measure of the rate of procollagen synthesis. Cultures which were the most sensitive to *cis*-hydroxyproline (Fig. 2) had the highest rate of procollagen synthesis (Table 1). Also, after mixed cultures of tendon fibroblasts and KB cells were grown in the presence of *cis*-hydroxyproline for 5 weeks, there was no apparent recovery of procollagen synthesis when the cells were subsequently subcultured without *cis*-hydroxyproline for 1 week. Morphologically the cells were similar to KB cells. These results suggest that the fibroblasts were effectively removed from the mixed cultures.

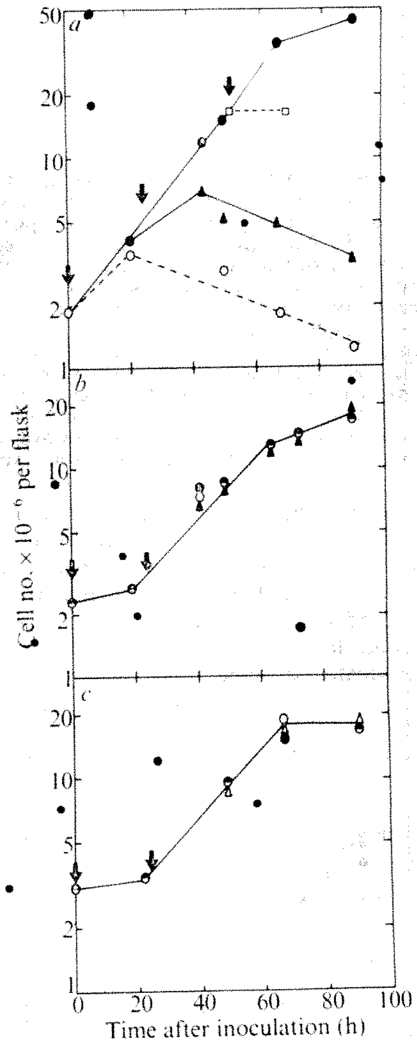

Fig. 1 Effects of *cis*-hydroxyproline on the growth of *a*, tendon fibroblasts; *b*, KB cells and *c*, neuroblastoma cells. Tendon fibroblasts were obtained from limited enzymatic digestion of tendon from 17-d-old chick embryos[8]. KB cells (CCL-17) and neuroblastoma cells (CCL-131) were from the American Type Culture Collection. The cells were grown in an atmosphere of 10% CO_2, and 90% air in Dulbecco's medium supplemented with 10% foetal calf serum, 100 units ml^{-1} of penicillin, and 100 μg ml^{-1} of streptomycin. The culture media were changed every other day after inoculation. *cis*-Hydroxyproline (100 μg ml^{-1}) was added to cultures at time indicated by arrow. Cell number per flask (Falcon; 75 cm^2) was estimated with a haemacytometer. Values presented are the mean from duplicate cultures. Cultures were grown in control conditions (●), or with *cis*-hydroxyproline added at time of inoculation (○), 24 h after inoculation (▲), or 54 h after inoculation (□).

The effect of *cis*-hydroxyproline on the growth of fibroblasts in culture might be explained by the previous observations indicating that when cells are incubated with proline

Table 1 Effect of *cis*-hydroxyproline on synthesis of non-dialysable ^{14}C-hydroxyproline by cell cultures

Cells	Treatment	^{14}C-hydroxyproline synthesised (d.p.m. per 10^7 cells per 30 min)
Tendon fibroblasts		5,691
L-929 fibroblasts		844
KB cells		< 100
Neuroblastoma		< 100
Tendon fibroblasts		4,974
Tendon fibroblasts + KB cells	+cHyp, 6 weeks*	< 100
Tendon fibroblasts + KB cells	+cHyp, 5 weeks; −cHyp, 1 week†	< 100

For labelling, medium was removed from each flask that contained $2-5\times10^7$ cells on the 6th day after the last subculturing and fresh medium (without *cis*-hydroxyproline) containing 1 μCi ml^{-1} of ^{14}C-proline was added (10 ml per flask) as described before[8]. In the second experiment, labelling period was 4 h instead of 30 min and values are reduced proportionally to make them comparable to the first experiment. Assay did not permit detection of less than 100 d.p.m. of ^{14}C-hydroxyproline.

* Mixed cultures (1:1) of tendon fibroblasts from chick embryos and KB cells were incubated continuously with 100 μg ml^{-1} of *cis*-hydroxyproline (cHyp) through 6 subcultures over 6 weeks.

† Mixed cultures (1:1) were incubated continuously with 100 μg ml^{-1} of *cis*-hydroxyproline through 5 subcultures over 5 weeks and then for a 6th subculture without the analogue for 1 week.

analogues, the analogues are incorporated into procollagen and the procollagen containing the analogues cannot become triple helical[1-7]. Several observations have suggested that the secretion and deposition of triple-helical collagen on surfaces used to culture cells may enhance the rate of growth of some fibroblasts *in vitro*[8-12]. It is possible therefore that *cis*-hydroxyproline limits the rate of fibroblast growth in the conditions employed here because it prevents the deposition of triple-helical collagen on the cell layer. This hypothesis, however, has not been explored in detail and it may well be that *cis*-hydroxyproline decreases the growth of fibroblasts in culture by some entirely unrelated mechanism. Nevertheless, use of *cis*-hydroxyproline is a simple technique which may be useful in preventing an overgrowth of fibroblasts, thus facilitating the preparation of primary cultures of other cell types. Other proline analogues which are incorporated into protein may be useful for the same purposes, although 0.2 mM (25 μg ml^{-1}) 3,4-dehydroproline was found not to inhibit the growth of L-929 fibroblasts[13].

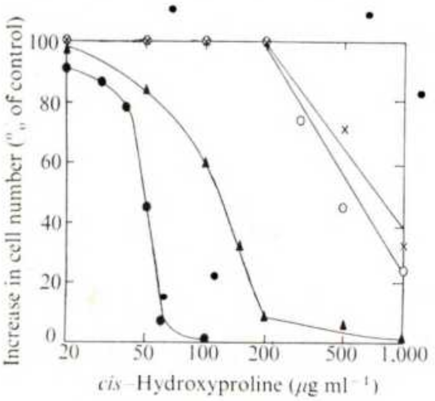

Fig. 2 Dose dependency of effect of *cis*-hydroxyproline on the growth of cells. Various amounts of *cis*-hydroxyproline were added to cultures at mid-log phase about 48 h after inoculation. In each case the experiment was terminated after the cell number in control cultures had doubled. Cells used were tendon fibroblasts (●); L-929 fibroblasts (▲); KB cells (○); and neuroblastoma cells (X).

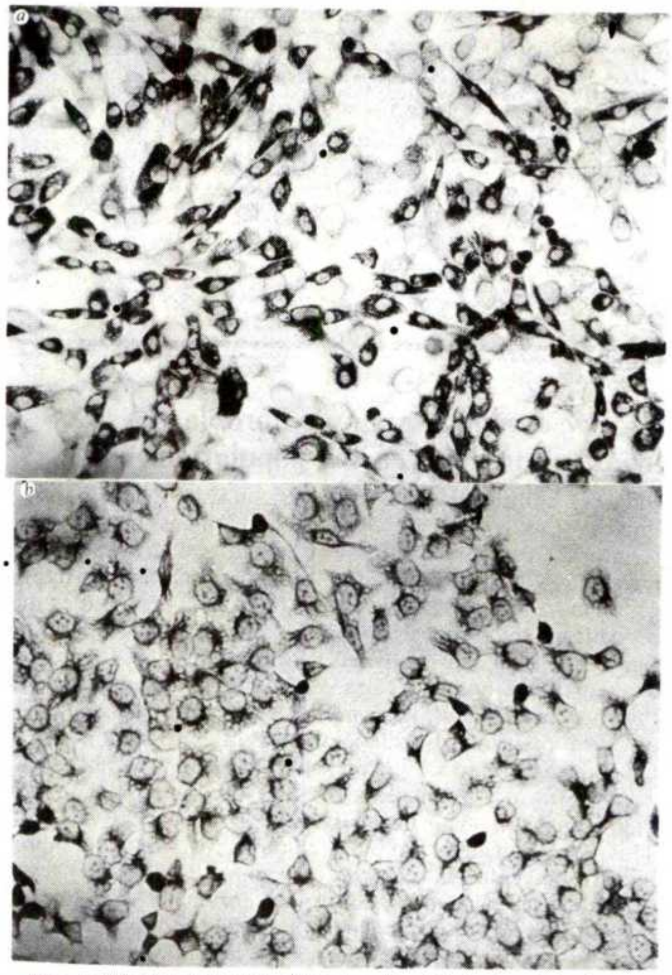

Fig. 3 Selective removal of tendon fibroblasts by *cis*-hydroxyproline from a mixed culture of tendon fibroblasts and KB cells. Equal numbers of tendon fibroblasts and KB cells were mixed and inoculated on coverslide inside a culture tube (Leighton type, Bellco) at a density of about 4×10^4 cm^{-2}. To half of the cultures 100 μg ml^{-1} of *cis*-hydroxyproline was added at the time of inoculation. The culture medium was changed every other day, and the cultures were maintained for 1 week. The cells on cover slides were fixed with ethanol–ether mixture, and then incubated with peroxidase conjugated to antibodies directed against chick prolyl hydroxylase. The samples were stained with 3,3′-diaminobenzidine as described before[9]. *a*, Photomicrograph of control sample. Tendon fibroblasts appear spindle shaped and are darkly stained. *b*, Photomicrograph of mixed cultures treated with *cis*-hydroxyproline. Only KB cells are seen; the few darkly-stained bodies probably represent dead cells.

We thank Ms Marie Zeydel for technical assistance, and the US Public Health Service for a grant. Antibodies to prolyl hydroxylase were a gift from Dr Richard A. Berg.

Prostaglandin E_2-9-ketoreductase as a mediator of salt intake-related prostaglandin-renin interaction

PREVIOUS studies have revealed a close relationship between the prostaglandin (PG) and the renin–angiotensin systems in the kidney[1–4] and we assume that both systems are intimately involved in the regulation of salt and volume homeostasis and of blood pressure. Changes in NaCl and water balance were found to be important determinants of the activity and function of the renin–angiotensin system[5] and it has been suggested that PG synthesis is also modified by these variables[2,6,7]. One factor influencing the pathway and, thus, the consequences of altered PG formation is the enzyme PGE_2-9-ketoreductase, which catalyses the interconversion of the antagonistically acting PGE_2 and $PGF_{2\alpha}$ (ref. 8). First direct evidence is presented here that PGE_2-9-ketoreductase activity is under the control of NaCl ingestion. We suggest that this enzyme is an important mediator of salt-intake-related prostaglandin–renin interaction.

PGE_2-9-ketoreductase activity has been demonstrated in the renal cortex and medulla of several species, including man and rabbit[9,10]. In our investigation in the rabbit, the effects of low and high NaCl ingestion on renal cortical and medullary PGE_2-9-ketoreductase and plasma renin activity were examined. Since urinary prostaglandin excretion is assumed to reflect renal prostaglandin biosynthesis[11], urinary PGE_2 and $PGF_{2\alpha}$ excretion were also measured (Table 1 and Fig. 1). At high NaCl intake, sodium excretion was nine times, but the urinary volume was only twice that at low NaCl intake. Plasma renin activity (PRA) was 12.9 ng ml^{-1} h^{-1} at low and decreased to 1.8 ng ml^{-1} h^{-1} at high NaCl intake. At low NaCl intake, urinary excretion of PGE_2 per day measured 1.9 μg and of $PGF_{2\alpha}$ 2.1 μg, giving a ratio of PGE_2 to $PGF_{2\alpha}$ of 1:1.1. PGE_2-9-ketoreductase activity in renal cortex was 0.61 ± 0.07 nM $PGF_{2\alpha}$ formed min^{-1} mg^{-1} (s.e.m., $n = 13$) and in the medulla 0.1 ± 0.01 (s.e.m., $n = 13$). At high NaCl intake, PGE_2-9-ketoreductase activity in the renal cortex increased threefold to 1.74 ± 0.13 (s.e.m., $n = 10$; $P < 0.001$) and in the medulla twofold to 0.19 ± 0.01 (s.e.m., $n = 10$; $P < 0.001$). At the same time urinary excretion of PGE_2 per day decreased to 0.53 μg, whereas that of $PGF_{2\alpha}$ remained practically unchanged at 2.43 μg, giving a ratio of PGE_2 to $PGF_{2\alpha}$ of 1:4.6.

The observed decrease in urinary PGE_2 excretion on high NaCl intake may result from either a decrease in renal PGE_2 synthesis, an alteration in PGE_2 metabolism at maintained synthesis, or both. The total amount of PGE_2 and $PGF_{2\alpha}$ excreted in urine decreased at high NaCl intake, suggesting a lower renal PG production. A reduction in formation or breakdown of PG endoperoxides, however, could only explain the lower PGE_2 excretion but not account for the unchanged $PGF_{2\alpha}$ excretion found on high NaCl intake. These findings can best be interpreted in terms of an altered pathway of PGE_2 metabolism on reduced PG synthesis. The increase of renal cortical and medullary PGE_2-9-ketoreductase activity, as demonstrated in this study during high NaCl intake, shifts intrarenal PG formation from PGE_2 to $PGF_{2\alpha}$, and could therefore explain the decrease in urinary PGE_2 excretion while $PGF_{2\alpha}$ excretion remains unchanged. Such a mechanism may be operative in man, since it has been observed in disease states in which variations in sodium and volume homeostasis are accompanied by changes in the PGE_2 to $PGF_{2\alpha}$ ratio[12].

The decrease of PRA after high NaCl intake confirms earlier observations[5] and reflects, in these conditions, a decrease in renin activity within the juxtaglomerular apparatus, which regulates synthesis and release of this enzyme. *In vitro*, renin release is increased by the PG precursor arachidonic acid, by PG endoperoxides or by PGE_2, whereas $PGF_{2\alpha}$ inhibits renin secretion[13,14]. $PGF_{2\alpha}$ may have this action also *in vivo*. Therefore, the decrease in PRA during salt-loading could result from the less opposed inhibitory action of $PGF_{2\alpha}$ on renin release. This assumption is supported by recent findings in man and dog, in which renin release decreased concomitant with increased sodium and $PGF_{2\alpha}$ excretion[15,16]. Thus, at high NaCl intake, the sodium-conserving renin–angiotensin system may be blocked by the relative increase in $PGF_{2\alpha}$ on reduced PG synthesis. In addition, distal nephron action of the antidiuretic hormone may be unopposed as a result of decreased PGE_2 formation[17,18]. These mechanisms would, at high NaCl intake, facilitate a high sodium load to be eliminated in a small urine volume, as demonstrated in our experiments (ninefold increase in urinary sodium excretion compared with twofold increase in urinary volume). At low NaCl intake the reverse was observed: PG synthesis may increase. PGE_2-9-ketoreductase activity is reduced, thereby increasing PGE_2 levels. Because of the stimulatory and relatively less opposed

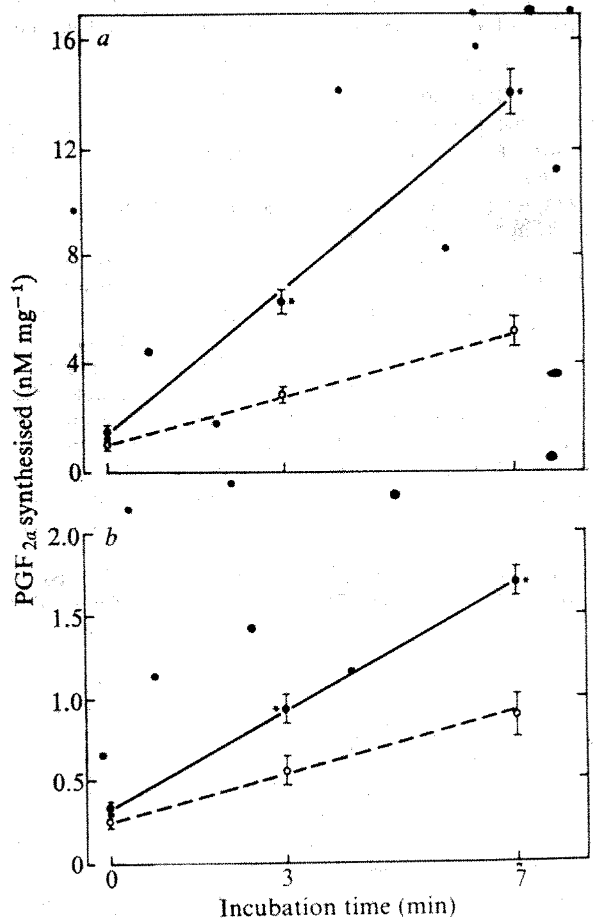

Fig. 1 Enzyme kinetic determinations of renal cortical (*a*) and medullary (*b*) PGE_2-9-ketoreductase activity of rabbits at low (○) and high (●) NaCl intake, respectively. Mean values are given as nM $PGF_{2\alpha}$ formed per mg protein (± s.e.m. $n = 13$ for low, $n = 10$ for high NaCl intake). NADPH-dependent PGE_2-9-ketoreductase activity was determined by the method of Stone and Hart[9] with minor modifications. Cortex and medulla of the removed kidneys were dissected at 4 °C. A 20% homogenate was prepared in 9.2 mM potassium phosphate buffer (*p*H 7.3) at a final concentration of 4 mM $MgCl_2$ and 0.1 mM 1,4-dithioerythritol (Merck, W. G.). The suspensions of cortex and medulla were centrifuged for 60 min at 100,000 *g*. The high speed supernatant fluids were dialysed for 24 h against 100 volumes phosphate buffer. Incubations were carried out at 37 °C using 200 μl supernatant as the source of PGE_2-9-ketoreductase, in a total volume of 600 μl phosphate buffer, at final concentrations of 1 mM $NADPH_2$ (Merck, W. G.) as cofactor and 1.2 mM PGE_2 (Upjohn, Kalamazoo) as substrate in excess (≥ fourfold K_M). At 0, 3 and 7 min, 100 μl of the mixture were removed. The reaction was stopped by adding 500 μl ice-cold Tris-HCl buffer (10 mM, *p*H 7.4, containing 0.1% gelatin and 140 mM NaCl), and heating the samples for 2 min to 100 °C. The amounts of $PGF_{2\alpha}$, enzymatically converted from PGE_2, were analysed by RIA (ref. 9). Reaction velocity of PGE_2-9-ketoreductase was calculated from the amounts of $PGF_{2\alpha}$ generated per minute and per milligram protein, determined by the method of Lowry *et al.* (ref. 25).

* $P < 0.001$. Level of significance between values obtained in rabbits on low and high NaCl diet was determined by the unpaired Student's *t* test.

Table 1 Effects of low and high NaCl intake on renal parameters in rabbits

NaCl intake (per 100 g food)	$U\dot{V}_{Na+}$ (mmol d^{-1})	$U\dot{V}$ (ml d^{-1})	Urinary PGE_2 excretion (μg d^{-1})	Urinary $PGF_{2\alpha}$ excretion (μg d^{-1})	PRA (ng ml^{-1} h^{-1})
Low: (13) 0.25 g	6.1 ± 0.4	146 ± 8	1.9 ± 0.1	2.1 ± 0.2	12.9 ± 1.2
High: (10) 2.50 g	53.8 ± 4*	295 ± 11*	0.53 ± 17*	2.43 ± 0.3	1.8 ± 0.3*

The effects of a sodium-depleted (0.25 g NaCl per 100 g food; or sodium-enriched (2.5 g NaCl per 100 g food) diet (Altromin, W. G.) on daily urinary sodium excretion ($U\dot{V}_{Na}$) and urinary volume ($U\dot{V}$), PGE_2 and $PGF_{2\alpha}$ excretion and PRA in cross-bred rabbits. Values are given as mean ± s.e.m. Numbers in parentheses indicate the number of animals. Experiments were carried out in rabbits kept in metabolic conditions for 10 d on either diet with drinking water *ad libitum*. Urinary parameters and PRA were measured in conscious animals the day before the kidneys were removed under pentobarbital anaesthesia for determination of renal PGE_2-9-ketoreductase activity. PRA was determined by radioimmunoassay (RIA) of angiotensin I as described previously[2,3]. PGE_2 and $PGF_{2\alpha}$ were analysed after previous extraction and group separation of the urinary PGs on silicic acid columns (Unisil, Clarkson Chemicals, Pennsylvania)[11,12]. PGE_2 was measured in parallel by bioassay of PGE_2 (ref. 24) and by RIA using a PGB-specific antibody after conversion of the PGE fraction to PGB[12]. The correlation between values obtained with both methods was highly significant ($y = 0.8x + 4.9$; $r = 0.94$). $PGF_{2\alpha}$ excretion was determined using a commercially available $PGF_{2\alpha}$ antibody (Calbiochem, Pennsylvania)[11,12].

* $P < 0.001$. Level of significance between values obtained in rabbits on a low and high NaCl diet was determined by the unpaired Student's *t* test.

action of PG endoperoxides or PGE_2 on renin release, the stimulated renin activity could then initiate the sodium-conserving mechanism[5]. In addition, at low NaCl intake, increasing PGE_2 levels may enhance distal tubular sodium reabsorption[18], and further support the effectiveness of the stimulated sodium-conserving renin-angiotensin system.

We therefore propose the concept that the activity of renal PGE_2-9-ketoreductase is dependent on NaCl ingestion or some factor related to salt intake. Our results suggest that this enzyme is intimately involved in adjusting the activity of the renin-angiotensin system and distal nephron function in response to varying levels of NaCl intake. Thus, renal PGE_2-9-ketoreductase may play a pivotal role in the regulation of NaCl and water balance. Finally, the demonstration of PG synthesis and of PGE_2-9-ketoreductase activity in blood vessel walls[19,20] may provoke new speculations on the finding that vascular reactivity and blood pressure are influenced by the state of NaCl balance (refs 21 and 22).

Myopia and eye enlargement after neonatal lid fusion in monkeys

THE aetiology of myopia has been studied mainly by investigating the distribution of refractive errors in human populations[1]. No clear conclusion has emerged, however, so the prevailing clinical attitude is that myopia can neither be prevented nor cured, but only corrected with appropriate lenses. The mechanism of myopia can be rationally analysed only if a suitable animal model is found for this refractive condition. In the literature, there are only two examples of experimental myopia. Levinsohn[2] claimed that a high degree of myopia develops in young monkeys when the body is kept elevated above the head for long periods of time; his results, however, have been questioned[3,4]. Young[5] induced myopia by exposing monkeys to a restricted visual space, but the refractive error thus obtained was relatively small. During investigations on monocular visual deprivation in monkeys[6] it was noted that the eye in which the lids had been closed by suture at birth developed a high degree of myopia. We report here a study of the effects of neonatal lid fusion on the refractive state and anatomy of the macaque monkey eye.

In 10 macaque monkeys (*Macaca mulatta*, *Macaca arctoides*) monocular or binocular lid fusion was performed at various times after birth. The surgical technique was as follows: under general anaesthesia, the margin of both lids was excised lateral to the lacrimal papilla. The conjunctiva was removed for an additional couple of millimetres to prevent its ingrowth into the wound and the cut surfaces of the lids were approximated by silk mattress sutures from the lateral canthus to the lacrimal papilla. Sutures were removed 1–2 weeks after surgery, when the lids had fused and appeared as a thin, translucent diaphragm that attenuated light by about half a log unit. After a variable period of lid fusion (19 d to 26 months) the palpebral fissure was re-established. Accommodation was paralysed with 2 drops of a 1% solution of homatropine and the refraction of both eyes determined by using a streak retinoscope and hand-held trial case lenses. The corneal curvature was measured with a keratometer and the fundus was examined. At various times after lid opening, animals were refracted again, used for electrophysiological studies on the visual pathways and finally perfused through the heart with 10%

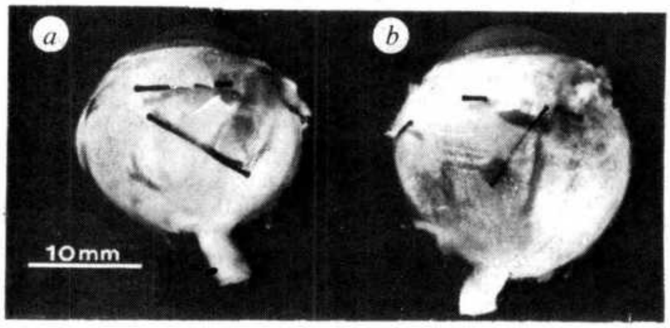

Fig. 1 Eyes of a rhesus monkey in which the lids on the right (*b*) were fused at the age of 2 weeks and opened 18 months later (experiment 5 in Table 1). Suture threads mark the insertions of the extrinsic ocular muscles. The left eye (*a*) was normal.

Don't take a chance on labelled compounds

Don't take a chance on finding the right labelled compound. We make a range of over 1500; you can bet one of them's made for you.

You needn't take chances with purity, either. Our manufacturing, Quality and Stock Control remove the risk of disappointment.

For special products, our custom synthesis and labelling services make sure you get exactly the compound you need.

Don't gamble on delivery. We deliver to most parts of the world in a couple of days. We work through local distributors who also act as our technical representatives.

Don't take risks with service. Our technical staff are on call whenever you need help. They regularly visit most parts of the world, and you can rely on them for information and advice.

We publish general interest reviews and technical bulletins. All are free on request.

Finally, here's your chance to try us. Write to us or 'phone. We'll send you our catalogue, the relevant literature and the name of your local agent.

TEXTBOOKS FROM plenum
the language of science

THE PMO THEORY OF ORGANIC CHEMISTRY by **Michael J. S. Dewar,** University of Texas, and **Ralph C. Dougherty,** Florida State University. "The book succeeds admirably in its stated aim of demonstrating the power of the PMO method, and does so in such a readable manner that it will be appreciated by a wide audience." *576 pages, illus., $42.00 hardcover, $15.00 softcover.*

PRACTICAL SCANNING ELECTRON MICROSCOPY: Electron and Ion Microprobe Analysis edited by **Joseph I. Goldstein,** Lehigh University, and **Harvey Yakowitz,** National Bureau of Standards. Foreword by **T. E. Everhart.** Provides step-by-step instructions for interpreting the output of the scanning electron microscope and the electron probe analyzer, as well as for selecting the right techniques for solving problems in the course of operation. *582 pages, illus., $42.00*

THEORY AND PRACTICE OF SOLID MECHANICS by **Thomas H. Dawson,** U.S. Naval Academy, Annapolis. Perfect for engineers and scientists, as well as students requiring an up-to-date introduction to advanced topics in solid mechanics, this important work deals with modern aspects of continuum mechanics, and with classical theories of elasticity, thermal elasticity, viscous elasticity, and plasticity of solids. *281 pages, illus., $29.40*

INTRODUCTION TO PLASMA PHYSICS by **Frances F. Chen,** University of California, Los Angeles. "This is the best introductory book on plasma physics yet published. The emphasis throughout is on providing physical insights into the principal concepts of the field, and it is the only book on the subject which makes extensive use of physical models, illustrating them with a large number of helpful figures. . . . I can heartily recommend this book . . ."—**Leonard M. Goldman,** *American Scientist. 329 pages, illus., $21.60*

CHEMICAL EQUILIBRIUM: A Practical Introduction for the Physical and Life Sciences by **William B. Guenther,** The University of the South. A modern presentation of aqueous chemical equilibrium, oriented to the needs of students and researchers in chemistry, biochemistry, geochemistry, and environmental fields, this important textbook goes beyond the traditional chemical treatment of the topic by presenting idealized models as well as their complete derivations. *248 pages, illus., $23.40*

QUANTUM MECHANICS OF ONE- AND TWO-ELECTRON ATOMS by **Hans A. Bethe** and **Edwin E. Salpeter,** Cornell University. An excellent source of reference for calculations pertaining to hydrogen-like and helium-like atoms. *370 pages, $10.74 softcover*

FOOD FOR LIFE by **F. E. Deatherage,** The Ohio State University. "Deatherage states that he has 'integrated . . . the basic concepts of physical, biological, and social sciences relevant to the problem of providing people with food.' The volume fulfills this objective in a rational and readable manner for scientist and layman alike. A must for any undergraduate collection."—*Choice. 422 pages,*

ELEMENTS OF ORGANIC PHOTOCHEMISTRY by **Dwaine O. Cowan,** The Johns Hopkins University, and **Ronald L. Drisko,** Essex Community College. A unique blend of theory, laboratory techniques, and experimental results in the field of photochemistry. Provides students with a solid introduction to the fundamental concepts, methodology, and reactions of organic photochemistry, while also serving as a reference source for chemists actively involved in research. *586 pages, illus., $33.00*

CONTEMPORARY QUANTUM CHEMISTRY: An Introduction by **J. Goodisman,** Syracuse University. A beautifully written text that offers the student an outstandingly clear and concise introduction to the theory and application of quantum mechanics. *approx. 370 pages, illus., $39.00 hardcover, $15.00 softcover*

INTRODUCTION TO BIOELECTRODES by **Clifford D. Ferris,** The University of Wyoming. "For the analytical microchemist, this text should be an excellent source book for techniques. . . . The clinical chemist should also add this text to his library. The text is written in a direct fashion and the theory is readily understandable. . . ." — **Samuel Natelson,** *Microchemical Journal. 243 pages, illus., $23.40*

ELEMENTARY PROBABILITY THEORY by **Melvin Hausner,** New York University. An introduction to probability theory that requires no background in calculus. This textbook, illustrating statistical and practical applications throughout, is ideal either for a one-term course in probability, or for the probability half of a one-year probability-statistics course. *310 pages, softcover, price not set*

STRUCTURE DETERMINATION BY X-RAY CRYSTALLOGRAPHY by **M. F. C. Ladd,** University of Surrey, England, and **R. A. Palmer,** Birkbeck College, University of London. Offers a detailed tutorial introduction to x-ray structure determination, including fundamental methods in

Circle No. 07 on Reader Enquiry Form.

structure analysis, as well as the heavy atom, isomorphous replacement, and direct methods techniques. *approx. 380 pages, illus., $42.00*

NEURAL MODELING: Electrical Signal Processing in Nervous Systems
by **R. J. MacGregor,** University of Colorado, and **E. R. Lewis,** University of California, Berkeley. Provides a comprehensive and integrated introductory survey of various computer, mathematical, and engineering models which have thus far been devised to describe, stimulate, embody or characterize the processing of electrical signals in the nervous system. *approx. 355 pages, illus., $30.00*

THE NONCLASSICAL ION PROBLEM
by **Herbert C. Brown,** Purdue University. With comments by **Paul von Ragué Schleyer,** Universität Erlangen-Nürnberg, West Germany. A brilliant and systematic dialogue between Brown and Schleyer on the evidence and arguments in favor of the controversial theory of nonclassical ions produced in solvolytic processes. *approx. 235 pages, illus., $29.40*

ADVANCED ORGANIC CHEMISTRY
by **Francis A. Carey** and **Richard Sundberg,** University of Virginia, Charlottesville. This essential new work, certain to become the standard text for advanced organic chemistry, offers a clearly written and well-organized treatment of all aspects of organic chemistry for the advanced undergraduate and beginning graduate student. *Part A* provides a thorough and detailed account of the basic structural aspects of organic compounds and of the mechanistic features of organic reactions. *Part B* emphasizes the synthetic application of organic reactions.
Part A: Structure and Mechanisms, *approx. 570 pages, illus., $47.40 hardcover, $15.00 softcover*
Part B: Reactions and Synthesis, *approx. 510 pages, illus., $47.40 hardcover, $15.00 softcover*

LIVING WITH OUR SUN'S ULTRAVIOLET RAYS
by **Arthur C. Giese,** Stanford University. Aimed at the reader with a minimal scientific background, this book critically examines both the harmful and healing effects of sunlight, and demonstrates how it influences human health. Emphasizes potential threats of a diminishing ozone layer and a variety of dangerous pollutants and discusses problems of skin damage, including sunburn, premature aging, and cancer induction as a result of exposure to the sun's rays. *185 pages, illus., $23.40*

INTRODUCTION TO VECTORS AND TENSORS
by **Ray M. Bowen** and **C.-C. Wang,** Rice University. Written especially for science and engineering students, this two-volume text presents a modern introduction to the basic concepts of vector and tensor analysis. *Volume 1: Linear and Multilinear Algebra* begins with a brief discussion of algebraic structures followed by a detailed examination of the algebra of vectors and tensors. *Volume 2: Vector and Tensor Analysis* concentrates primarily on the analytical and geometrical aspects of vector and tensor fields. Volumes in the Mathematical Concepts and Methods in Science and Engineering series, **Angelo Miele,** editor.
Volume 1: Linear and Multilinear Algebra, *241 pages, illus., $23.40*
Volume 2: Vector and Tensor Analysis, *193 pages, illus., $23.40*

THE GENESIS STRATEGY: Climate and Global Survival by **Stephen H. Schneider,** National Center for Atmospheric Research, with **Lynne E. Mesirow.** "This brilliant book by a young, concerned scientist is just what the world needs . . . Relevant, timely, essential . . . buttressed with facts—but not too many for the layman to digest as a preparation for action."—**Margaret Mead.** *Selected by major book clubs. 419 pages, illus., $17.94*

CONTEMPORARY TOPICS IN ANALYTICAL AND CLINICAL CHEMISTRY: Volume 1 edited by **David M. Hercules,** University of Pittsburgh, **Gary M. Hieftje,** Indiana University, **Lloyd R. Snyder,** Technicon Instruments Corporation, and **Merle Evenson,** The University of Wisconsin. A new series designed to provide the research chemist with the most up-to-date coverage of progress in analytical and clinical chemistry. *Volume 1* features discussion on: high speed liquid chromatography of proteins; chemiluminescence and bioluminescence analysis; environmental studies of the atmosphere with gas chromatography; photodiode arrays for spectrochemical measurements; and the application of ESCA to the analysis of atmospheric particulates. *approx. 300 pages, illus., 1977, $30.00*

OUR FRAGILE WATER PLANET An Introduction to the Earth Sciences by **C. L. Mantell,** New Jersey Institute of Technology and Consulting Chemical Engineer, and **A. M. Mantell.** Written in language easily comprehensible by the student, yet sufficiently technical to be of interest to the specialist, this important new book provides an authoritative introduction to the structure of the earth and the forces that shape it—both natural and man-made. *221 pages, illus., $23.40*

DIGITAL ELECTRONICS AND LABORATORY COMPUTER EXPERIMENTS by **Charles L. Wilkins,** iversity of Nebraska, **Sam P. Perone,** Purdue University, **Charles E. Klopfenstein,** University of Oregon, **Robert C. Williams,** University of Nebraska, and **Donald E. Jones,** Western Maryland College. An excellent laboratory manual designed to teach by example the basic principles of digital electronics and minicomputer applications in the laboratory. *283 pages, illus., $18.00*

*Expressed as a ratio between axial length of the myopic eye and axial length of the normal eye.

formalin. The eyes were enucleated, measured and processed for light microscopy; in some animals, the extraocular muscles were prepared for microscopy.

To illustrate the effects of monocular lid fusion on the refraction and the anatomy of the eye, we describe an experiment in which results were striking and a comprehensive morphological analysis was performed (experiment 5 in Table 1). Lids were sutured in the right eye of a rhesus monkey at the age of 2 weeks and the fusion maintained for 18 months. Upon re-establishing the palpebral fissure, a normal conjunctival sac was found and the appearance of the exposed surface of the eye globe was identical to the control side. The interocular difference in curvature of the anterior corneal surface was slight (average refractive power in the right eye 51 dioptres, in the left eye 52.5 dioptres). Retinoscopy showed that the dioptric media were normally transparent and that the right eye was 13.5 dioptres more myopic than the left eye. The appearance of the fundus was normal; furthermore, the physiological experiments indicated that the lateral geniculate bodies received normal retinal input from both eyes.

At autopsy, the right eye was considerably larger than the left eye (Fig. 1). Various eye dimensions were measured and some of the results are diagrammatically represented in Fig. 2. The most remarkable finding was a 21% increase in the axial length of the right eye, as measured from the summit of the cornea to the projection of the fovea on the sclera (corresponding to the point of entry of the lateral long posterior ciliary artery and long ciliary nerve into the eye globe); the increase in equatorial diameter of the right eye was 7% only. Corneal diameters and distance of the insertions of the rectus muscles from the limbus were identical in both eyes, whereas the linear distance of the muscle insertions from the optic nerve was 23% larger in the right eye. Finally, the distance of the fovea from the centre of the optic disk was 18% larger in the myopic eye.

Histological examination showed that the posterior sclera was thinner in the right eye. Thickness of the cornea, choroid and retina were identical in both eyes. Also identical were the cross-sectional area of the ciliary muscle, the diameter of the optic nerve, the structure of the optic nerve head, and the cross-sectional area of the extrinsic ocular muscles.

Thus, neonatal lid fusion caused an elongation of the eye globe, characterised by distension of the postequatorial hemisphere and attenuation of the posterior sclera. All remaining ocular structures seemed unchanged.

Table 1 lists the results of all of our monocular lid fusion experiments. It shows that the degree of myopia caused by lid fusion increased with the duration of closure, that the error of refraction was less pronounced when lids were fused in older animals, and that there was no change in the adult. It should be noted that there was some variability in the response of different individuals to lid fusion, but that all animals in which lids were fused early in life became myopic.

In order to establish whether the refractive error was caused by a functional imbalance between the eyes, lids were fused bilaterally in a rhesus monkey at the age of 5 weeks. Eleven months later, −11-dioptre myopia was present bilaterally and both eyes were equally enlarged. In another instance, lids were fused in the right eye of a rhesus monkey at the age of 1 week and opened 12 months later; a −10-dioptre myopia was present in the sutured eye. Lids were subsequently fused in the left eye and opened 13 months later; this eye only developed a −6-dioptre myopia. The axial length was 23.25 mm in the right eye and 22 mm in the left eye (the average axial length of the eye in the mature rhesus monkey was 19.34 mm ±0.14 s.e.m., measured in 15 animals, right and left eyes pooled). These experiments confirm that larger refractive errors are obtained in younger animals and demonstrate that the development of myopia in each eye is independent of the functional state of the other eye. Finally, it is important to mention that myopia persists unmodified for years after lid opening.

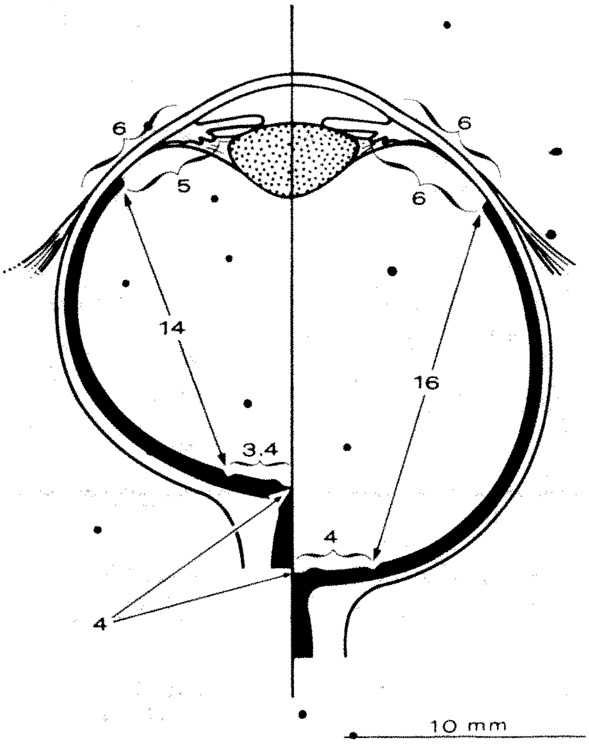

Fig. 2 Diagram illustrating the effects of neonatal lid fusion on various eye dimensions. The temporal halves of the eyes are juxtaposed. (Experiment 5 in Table 1.)

The myopia caused by lid fusion is clearly of the axial type, for the corneal refraction is not affected significantly.

The fact that the refractive error is larger when lid fusion is performed early in life, suggests that this type of myopia represents a derangement of the development of the eye. Presumably, neonatal lid fusion somehow accelerates and accentuates a mechanism which operates normally in postnatal life. Supporting this interpretation is the finding that the postequatorial segment of the globe elongates, whereas the anterior segment is relatively unaffected: in fact, it is known that in humans the cornea changes but little after birth, whereas the axial length increases dramatically[1]. The simplicity and effectiveness of the technique and the fact that one eye can be used as a control, indicate to us that monocular myopia caused by neonatal lid fusion in monkeys represents a useful animal model for myopia in general, and that a study of its pathogenesis may provide insight into the development of this refractive error in humans. After a presentation of our results[7], G. K. van Noorden reported inconsistent changes in refraction following lid fusion in neonatal rhesus monkeys; we have no explanation for the discrepancy.

We thank Dr Prabhat Sehgal and Ms Ellen Newhouse, of the New England Regional Primate Research Centre, for assistance. This investigation was supported by grants of the National Eye Institute, United States Public Health Service.

Remyelination of CNS axons by Schwann cells transplanted from the sciatic nerve

SCHWANN cells can remyelinate axons normally myelinated by oligodendrocytes, after either primary demyelination[1–3] or suppression of myelination by X irradiation at the time of myelination[4,5]. It has been suggested that the glial limiting membrane normally inhibits Schwann cell invasion of the CNS (ref. 2) and its reformation inhibits uncontrolled invasion by Schwann cells once this phenomenon has been initiated[1,2]. The Schwann cells in these situations are thought to arise from the nerve roots. I undertook experiments to determine whether it is possible to suppress remyelination following primary demyelination in an experimental animal. If so the resulting demyelinated axons would be similar to those present in the multiple sclerosis plaque, that is they would remain demyelinated unrepaired by glial or Schwann cells. Using such a lesion it would then be possible to establish if Schwann cells obtained from a source outside the central neuraxis would remyelinate these axons. In the past, attempts at transplanting peripheral nervous tissue into the central nervous system have shown very limited invasion of peripheral elements into the neuropil of the CNS (refs. 6, 7) and it was hoped that the presence of large numbers of demyelinated axons would act as a stimulus for Schwann cell invasion[8]. In addition, intraspinal injections of lysolecithin facilitate Schwann cell invasion of the CNS from local sources[2–9]. By abolishing this intrinsic Schwann cell remyelination potential and by substituting an extrinsic source of Schwann cells it might be possible to determine if persistently demyelinated axons in the CNS, similar to those in multiple sclerosis plaques, can be repaired by outside interference. I report here the preparation of areas of demyelination in rats and cats which remyelinated only in the presence of added Schwann cells.

The first step was to induce an area of primary demyelination which was incapable of being remyelinated with the cells available within the central neuraxis, that is, by oligodendrocytes or by Schwann cells derived from the spinal roots.

Intraspinal injection of lysolecithin (lysophosphatidyl choline) induces an area of primary demyelination at the site of injection in rats and cats[2–9] and all the demyelinated axons are subsequently remyelinated either by oligodendrocytes or Schwann cells depending on their location within the lesion. In order to suppress this remyelination the spinal cord caudal to Th_{10} spinal level was irradiated 2 weeks before the injection of lysolecithin with 4,000 rad of X rays (from a Marconi radiotherapy machine using 250 kV, 15 mA, 0.5 mm Cu, 1 mm Al, f.s.d. 50 cm for cats and 32 cm for rats, under pentobarbitone anaesthesia). In rats and cats subjected to this procedure there was no evidence of remyelination when they were subsequently killed (Table 1 and Fig. 1). These experiments therefore established that X irradiation with 4,000 rad before demyelination suppresses both oligodendrocyte and Schwann cell remyelination, leaving large numbers of persistently demyelinated axons in the spinal cord (Fig. 1).

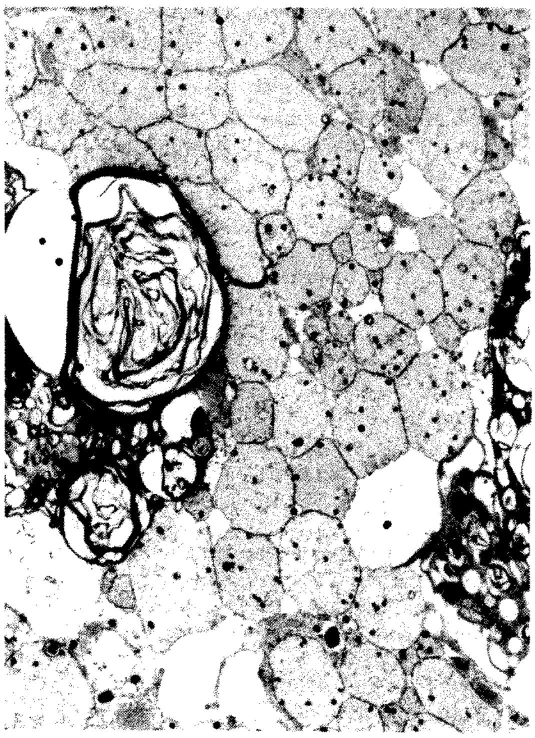

Fig. 1 Persistently demyelinated axons in the dorsal column following lysolecithin injection into the X-irradiated spinal cord (rat R53). (×4,400.)

In the second series of experiments with these two species a 1.0-cm length of dissociated sciatic nerve was placed over the injected area to provide a source of viable Schwann cells. The experimental procedure was as follows. At the time of spinal cord irradiation the cat or rat sciatic nerve was crushed at the mid-thigh level. A laminectomy was carried out 2 weeks later in the region of Th_{12-13}, the dura were incised and lysolecithin was injected into the dorsal columns as before[2–9]. In most cases 3–5 μl of a 1.0% solution of lysolecithin (Sigma) in saline were injected in up to three sites using a hand held glass micropipette attached to an Aglar syringe (Wellcome reagents) by means of fine polythene tubing. A 1.0-cm length of sciatic nerve was then excised distal to the previously made crush, desheathed and slightly teased in tissue culture media

Table 1 Relationship between experimental treatment and remyelination

	Experimental treatment				Type of remyelination			
Animal	Lysolecithin	Iradiation	Transplantation	Survival time	Oligodendrocyte remyelination	Schwann cell remyelination	Persistent demyelination	Comments
Rats

T, Treatment given; O, treatment omitted; –, none; +, some; + +, many; + + +, very many; W, week; d, days.

under a dissecting microscope. The teased mass was placed over the exposed surface of the spinal cord and tucked under the dura. In some cases it was also pushed into the substance of the cord in the region of the lysolecithin injections. The wound was closed and animals were killed at various times after these procedures (Table 1) by aortic perfusion with 4% glutaraldehyde in phosphate buffer under pentobarbitone anaesthesia. The cord was removed and 1–2-mm transverse slices from the injected area were post fixed in osmium tetroxide and embedded in Araldite. The effects of transplantation were assessed using 1-μm sections stained with alkaline toluidine blue.

In all animals which received nerve transplants, with the exception of cat R131, Schwann cell remyelination was present in the areas demyelinated by the injection of lysolecithin (Table 1) (Fig. 2). The extent of Schwann cell remyelination varied but in general was greater in the rats than the cats. Not all demyelinated axons were remyelinated, which in the rats may be related to the short survival times; however in the cats this failure to remyelinate completely may be due to other factors because the persistently demyelinated axons occurred deeper in the cord than those remyelinated by the Schwann cells. In the rats lesions in the ventral columns present in animals R109 and R110, showed no evidence of remyelination confirming the results found in the non-transplanted animals that the dose of irradiation used suppresses inherent remyelination.

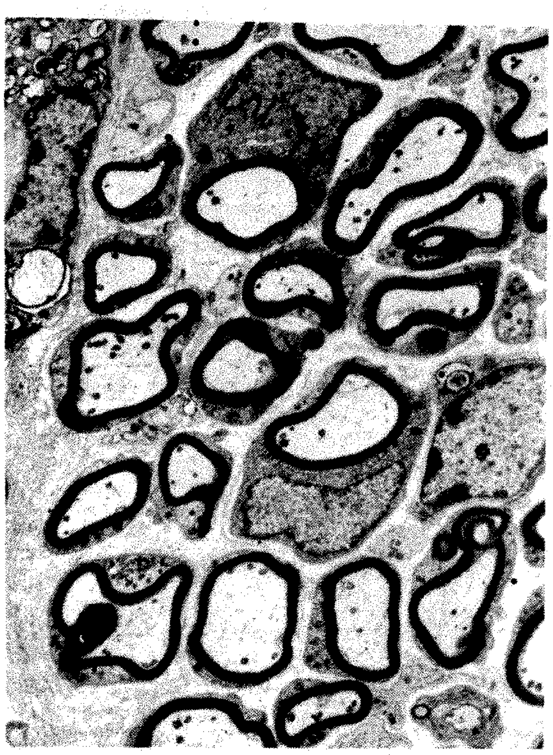

Fig. 2 Schwann cell remyelination following transplantation of sciatic nerve (rat R111). ×4,400.

These experiments show that it is possible to prepare small localised areas of primary demyelination in experimental animals which do not remyelinate (Fig. 1); in this they resemble the persistently demyelinated plaques of multiple sclerosis. When a source of Schwann cells is provided the axons are remyelinated by these cells (Fig. 2); this is most marked with axons close to the transplanted cells but more distant axons may remain demyelinated. Although the experimental system used to demonstrate this phenomenon is grossly abnormal, indeed is potentially lethal to the animal, it does show that it is possible to repair areas of demyelination which if left alone would remain demyelinated. The implication of this observation to human neurology must be considered, and factors which influence Schwann cell behaviour once they gain entry into the CNS should be studied. It remains to be determined if the presence of Schwann cells within the CNS is ultimately beneficial or harmful.

Anaesthetic and convulsant ethers act on different sites at the crab neuromuscular junction *in vitro*

ATHOUGH volatile general anaesthetics, of the so called structurally non-specific type, have been shown to affect synaptic transmission[1,2], the underlying mechanisms are unknown. In view of their oil solubility, it has been suggested that these anaesthetics owe their depressant effect to the ability to induce non-specific disordering of membrane lipids[3,4]. But some equally oil-soluble and structurally non-specific ethers are potent convulsants rather than anaesthetics[5] and theoretical considerations suggest[6] that the two groups act at different sites in the nervous system and therefore are more specific in action than assumed so far. In support of this, we now report that each of a pair of representative agents, methoxyflurane, an anaesthetic and hexafluorodiethylether (HFE, Indoklon, Ohio Medical and Surgical Suppliers), a convulsant, have different effects on excitatory or inhibitory transmission at the crab neuromuscular junction. We have found that in the adductor muscle of the crab, *Ocypoda cursor*, which contains both glutamate and γ-amino-butyrate (GABA) receptors, methoxyflurane blocks the action of glutamate but not of GABA, while HFE blocks the effect of GABA but not of glutamate.

Muscle fibre cells were impaled with two micropipettes filled with 2 m KCl and having a resistance of 1–3 MΩ. One electrode recorded voltage and the other injected current. Usually, hyperpolarising current pulses of 100–500 nA and 100–200 ms were used to measure the effective input resistance of the cells. The voltage, V, and current, I, traces were amplified suitably and recorded on chart paper (Grass Polygraph model 79c). Membrane conductance, G, was computed as $G = I/V$. The preparation was perfused continuously with medium containing the desired drug at 22 ± 2 C. The working concentrations of methoxyflurane and HFE were set at their clinically effective blood levels[11,12].

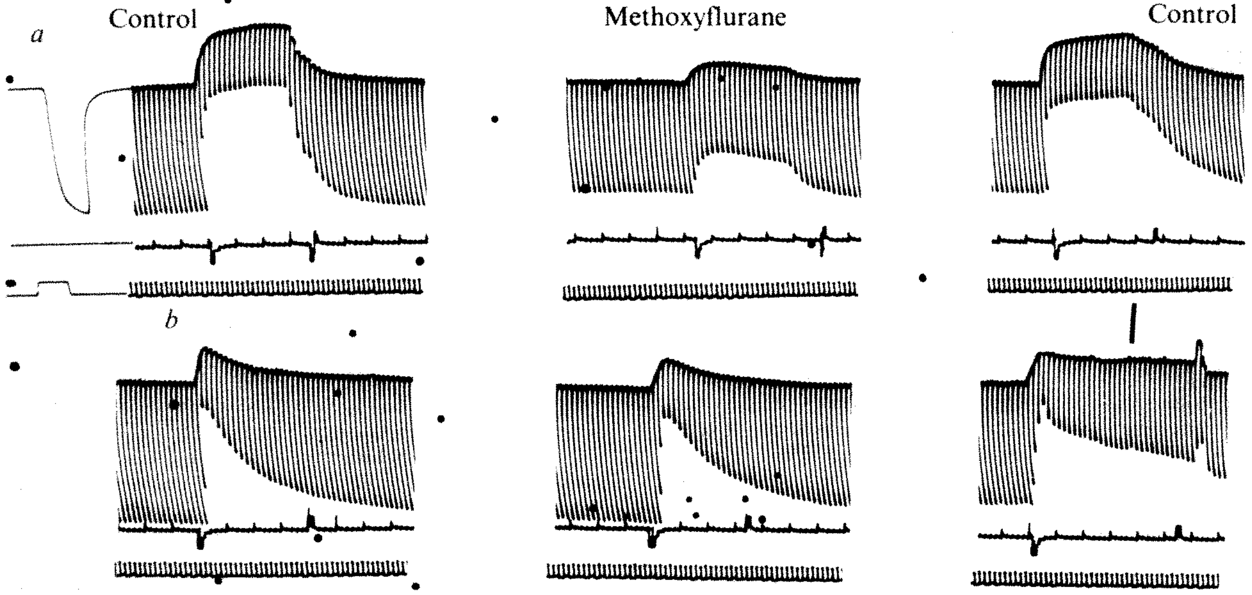

Fig. 1 Intracellular recording of the effect of 10^{-4}M methoxyflurane, $CHCl_2CF_2OCH_3$ on glutamate-induced *(a)* and GABA-induced *(b)* conductance change in a cell from the adductor muscle of *Ocypoda cursor*, resting potential −75 mV, input impedence 60 kΩ. *a*, Voltage changes caused by square current pulses of 200-nA amplitude and 100-m duration in the following order: with 5×10^{-5}M glutamate; with glutamate and methoxyflurane; and with glutamate after removal of methoxyflurane. *b*, In the same sequence, voltage changes in the presence of 5×10^{-5}M GABA; GABA and methoxyflurane and GABA after removal of methoxyflurane. Time scale: 1 and 5-s marks. Downward deflection on time scale indicates start of transmitter application; upward deflection indicates its termination. Calibration, 5 mV and 500 nA. In these and subsequent experiments, the composition of the bathing solution was, in mM: NaCl, 453; KCl, 12.8; $CaCl_2$, 34; $MgCl_2$, 4.9; Tris buffer, 2. Muscle fibres were dissected and mounted according to Parnas *et al.*[13].

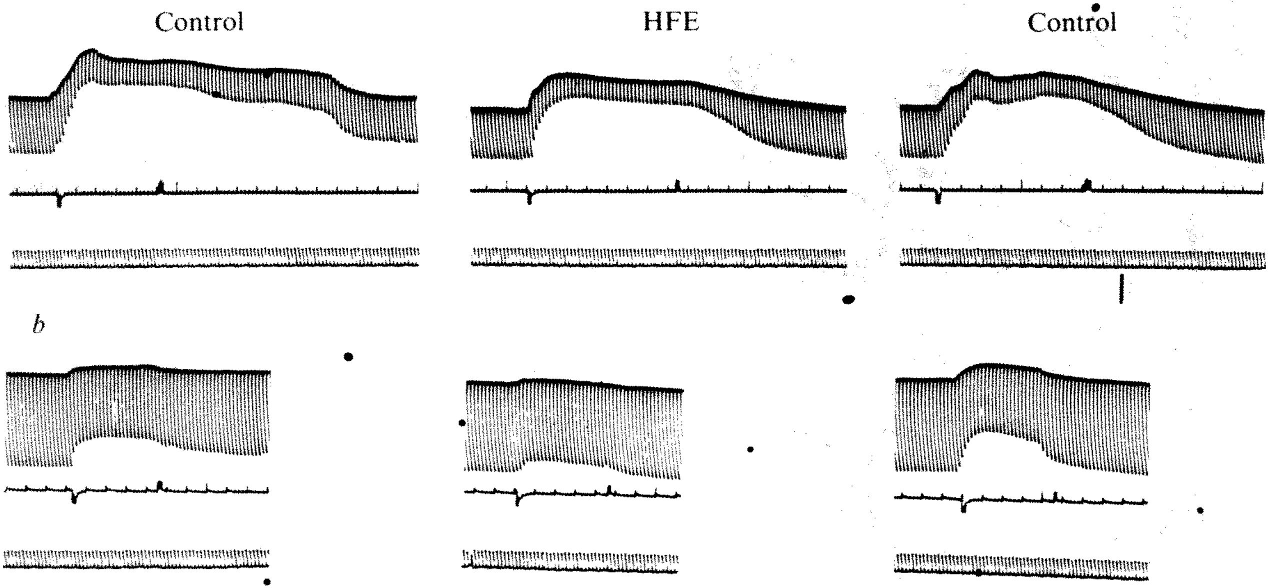

Fig. 2 Intracellular recording showing the effect of 10^{-4}M HFE, $CF_3CH_2OCH_2CF_3$, on glutamate-induced *(a)* and GABA-induced *(b)* conductance change in a cell from the adductor muscle of *Ocypoda cursor*, resting potential −78 mV and input impedence 25 kΩ *(a)* and 45 kΩ *(b)*. *(a)* and *(b)*, Voltage changes are shown in the same order and the deflections have the same significance as in Fig. 1. Calibration, 5 mV and 300 nA. Experimental conditions were the same for Fig. 1.

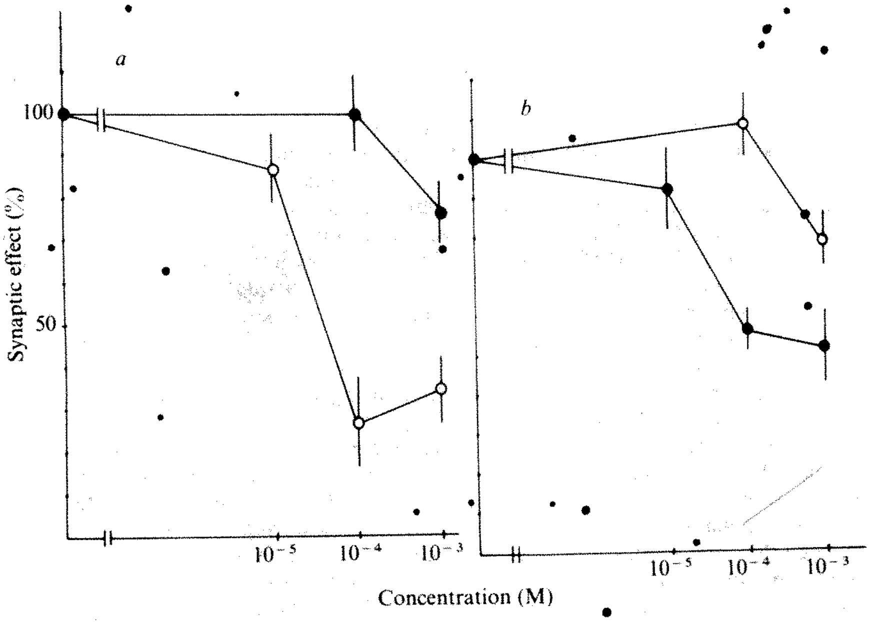

Fig. 3 Dose dependance of the depressing effect of methoxyflurane (○) and HFE (●) on glutamate-induced *(a)* and GBA-induced *(b)* conductance change. The ordinate is percentage change with respect to control. Bars indicate standard deviation. Data for 10^{-4} M are averages from eight cells; those for 10^{-3} M and 10^{-5} M are averages from the five cells each.

Figure 1 shows results from a typical experiment with 10^{-4} M methoxyflurane. When at first the preparation was perfused with 5×10^{-5} M glutamate only, the muscle was depolarised and its input impedence decreased markedly. But after exposure of the cell to methoxyflurane for 5 min, followed by methoxyflurane and glutamate, the latter elicited a much reduced response. Eventually, when methoxyflurane was washed out, the original response to glutamate could be fully restored. This blocking effect of methoxyflurane was seen in eight cells where glutamate-induced conduction was reduced to $26\pm4\%$ of control. In identical conditions, methoxyflurane did not block the action of GABA, which induced slight depolarisation and a marked reduction in membrane resistance. In eight experiments, the effect of GABA in the presence of methoxyflurane remained at $108\pm3\%$ of control.

Opposite results were obtained with the convulsant, HFE (Fig. 2). No effect of 10^{-4} M HFE was recorded on the action of glutamate. Thus, glutamate-induced conduction in the presence of HFE was $99\pm3\%$ ($n=8$) of control. On the other hand, 10^{-4} M HFE blocked the synaptic effect of GABA, and GABA-induced conduction was reduced to $56\pm2\%$ of control ($n=8$). This apparent specificity of action in one type of synaptic transmission rather than in the other became less pronounced with higher concentrations of drugs. Thus, at 10^{-3} M, either drug suppressed the action of both glutamate and GABA (Fig. 3); methoxyflurane remained more active with respect to glutamate while HFE was more active with respect to GABA.

We infer that the blocking mechanisms of these drugs at the molecular level are basically the same, but that they differ in potency with respect to function. Measurements in the exophase show that the equipotent molar ratio of methoxyflurane to HFE is about 1:100 in depressing glutamate transmission but 100:1 in depressing GABA transmission. Glutamate and GABA are believed to be excitatory and inhibitory transmitters in the crab, respectively[7]; and probably they have similar functions in the mammalian central nervous system (CNS)[8,9]. Extrapolated to CNS receptors[2-10], our results may explain why methoxyflurane is an anaesthetic whereas HFE is a convulsant. Also, the specificity of action of each agent seems to be incompatible with a model whereby the drugs produce a non-specific disordering of bulk membrane lipids[3,4]. Rather, they seem to affect distinctive sites, probably functionally different proteins embedded in the same membrane.

Pathways for hydraulically and osmotically-induced water flows across epithelia

EVIDENCE linking an extracellular shunt pathway[1] for ions with intercellular junctions[2], with reports that those junctions are permeable to large molecules such as sucrose[3], inulin[3], lanthanum hydroxide[4] and horseradish peroxidase[5] in various fluid-transporting epithelia suggests that water could also traverse this pathway. There is evidence, moreover, for a high hydraulic-conductance pathway across gastric mucosa[6] and rumen[7] if hydrostatic pressure is the driving force. Yet, except for the kidney proximal tubule[8], measurements of osmotically-induced water flows across several 'leaky' epithelia have not in general yielded values[9] consistent with a high-conductance pathway. It has been argued, also, that the extracellular shunt is not a significant route for osmotic flow in the gallbladder[10]. To investigate these apparent discrepancies, we have measured the hydraulic (Lp) and osmotic (P_{os}) conductances of rabbit corneal endothelium. We report here that a large conductance for both hydraulic and osmotic flows either is present or can be demonstrated in appropriate conditions, and that its value is of the order expected for bulk water flow across the intercellular junctions.

The techniques for the dissection and mounting of the preparation, and the bathing medium's composition have been described before[11]. The corneal epithelium was scraped off. The rates of transendothelial fluid movement and the corresponding steady-state values of *Lp* and P_{os} were determined by an automatic technique[12] which maintains the volume of the outside compartment constant. The transient rates from which P_{os} at zero time was extrapolated were determined by microscopic measurements of corneal thickness[13].

The effect of a hydrostatic pressure difference (ΔP) on the rate of fluid movement was determined as described in Fig. 1. The basal rate of fluid transport was usually measured with a ΔP of 5 or 10 cm H_2O. After each change in ΔP there was a transient, followed by a period of reasonable stability. The effects were reversible during the 5–6 h of useful life of the preparation, then *Lp* increased progressively (Fig. 1), presumably due to cell deterioration. The long transients (Fig. 1) were attributed to changes in the thickness of the supporting stroma with ΔP. Evidence came from separate observations of isolated stroma; endothelium was scraped off and silicone oil (20 cs) filled the inside (or aqueous) chamber, which limited water movements to the stromal-outer chamber interface. Transient changes in rate of water movement due to changes in ΔP had the same amplitude and time course as those seen with endothelium present.

The results of all technically acceptable experiments are plotted in Fig. 2, and show that the flow is linear with the ΔP for most of the range examined. At the low end of that range there is a trend towards an increased dependence of flow on ΔP, but this point could not be substantiated by reversing the ΔP because of technical limitations. For the linear interval, *Lp* was estimated from Fig. 2 to be 83±11 μm s^{-1} (V_w at 37 °C: 1.81 cm^3 m^{-1}). 'Edge damage' was excluded as an influence in this value by mounting the preparation in the chamber, then clamping it with a cylindrical plug which left exposed only a 0.1-mm peripheral annulus. No leak was detected across this preparation even with a ΔP of 150 cm H_2O. To account for possible solute polarisation in the unstirred layers on both sides of the tissue, which could have led to an underestimation of *Lp* (ref. 14), we assumed that an increase in ΔP induced an outward flow which diminished the apparent inward flow due to transport. Unstirred layer widths and NaCl diffusion coefficients were either taken from the literature or assumed (inside: $\delta_1 = 350$ μm; $D_1 = 1.54 \times 10^{-5}$ cm^2 s^{-1}; outside: $\delta_2 = 850$ μm; $D_2 = 1.0 \times 10^{-5}$ cm^2 s^{-1}); taking for the basal rate of fluid transport a value of $Jv = 4.5$ μl h^{-1} cm^{-2} at a ΔP of 10 cm H_2O (Fig. 2), substituting into $C = C_{bulk} \exp(-Jv\,\delta/2D)$ (see later) for each interface and using $\sigma_{NaCl} = 0.6$ (ref. 15) the corrected *Lp* is 114 μm s^{-1}.

To determine P_{os}, inward flow was induced by making the inside solution hypertonic with sucrose, while outward flow was induced by making both sides initially 80 mOsm hypertonic with sucrose and then lowering the tonicity inside. The results summarised in Fig. 3 show that the steady-state osmotic flows are not linear with the osmotic pressure difference ($\Delta\pi$), just as is the case in other epithelia[9]. These steady-state osmotic flows were, however, preceded by transients, which prompted an investigation of the osmotic flows obtained shortly after the imposition of a $\Delta\pi$. The results in Fig. 4 show that for the range $10 < \Delta\pi < 80$ mOsm the initial rate of osmotic flow is linear with $\Delta\pi$. The slope for the linear region (Fig. 4) is 166±12

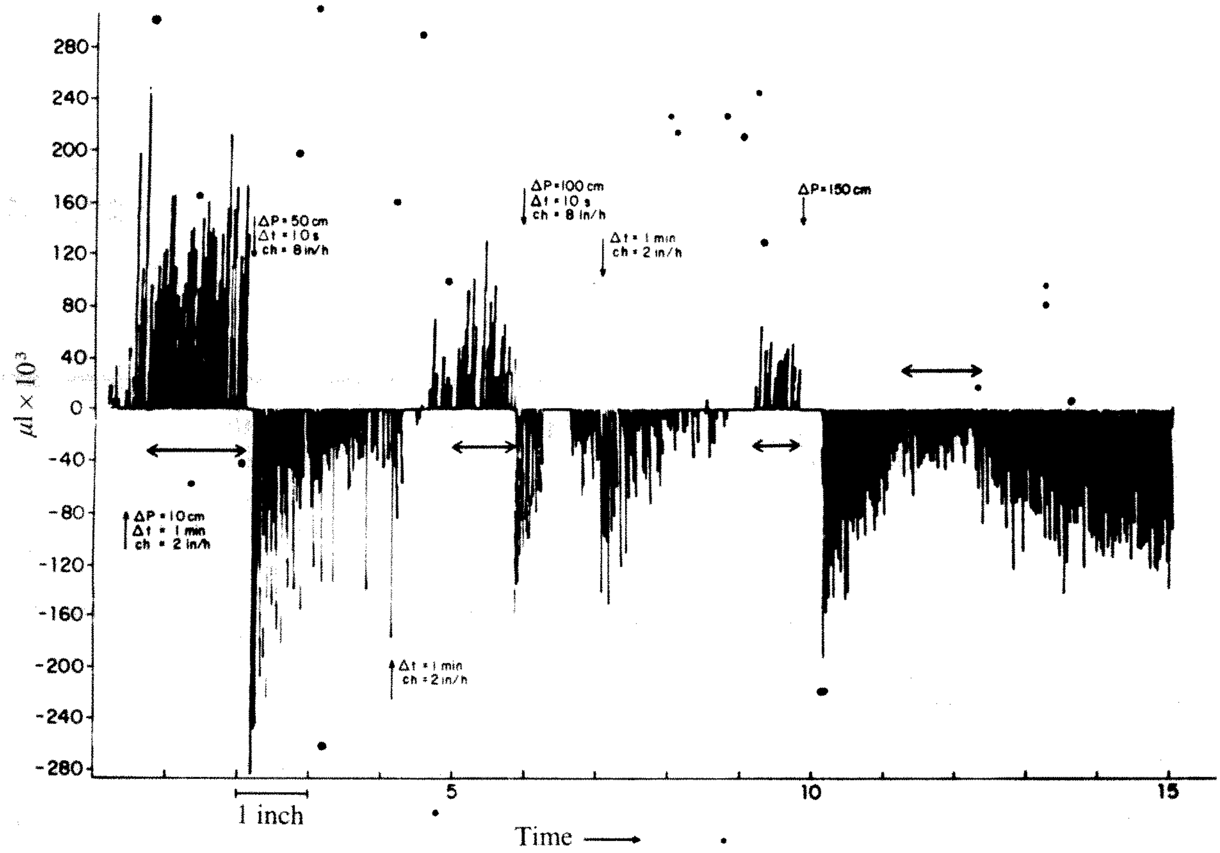

Fig. 1 Photograph of an experimental record. The height of the bars corresponds to the volume of fluid that traverses the preparation and is subsequently reinjected into (or aspirated from) the outside compartment by a stepping-motor-driven syringe. The recorder is reset to zero at time intervals Δt, so that a graphical display of the rate is obtained. The preparation was supported by a hemispherical stainless steel net, against which it was held by hydrostatic pressure applied on the inside (aqueous side). Chart markings are at 1-inch intervals; changes in ΔP, Δt and chart speed are shown at arrows. Positive ordinate denotes inward flow (from stroma to aqueous) and vice versa. In this experiment most of the stroma was dissected away. Average rates were computed from an accumulator for the periods denoted by horizontal bars. $T = 36.80 \pm 0.01$ °C; area of preparation = 175 mm^2.

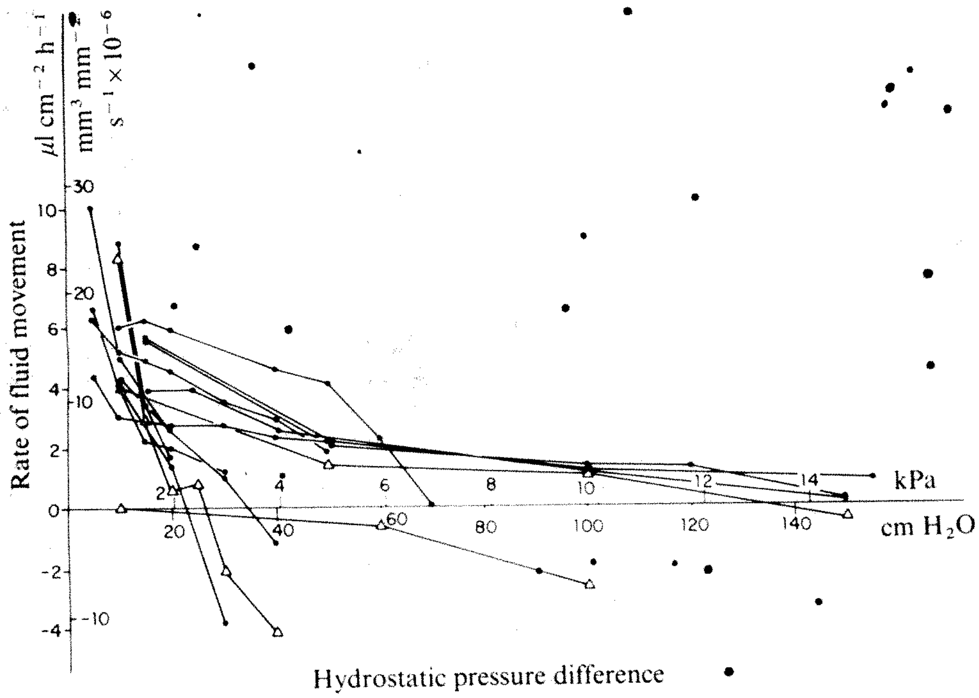

Fig. 2 Rate of transendothelial fluid movement with different values of hydrostatic pressure difference across that layer. Each curve represents an experiment; ●, the usual type: △, experiments in which most of the stroma was dissected away. Direction of flow and applied pressure as in Fig. 1. (kPa: kilopascals.)

µm s^{-1}; the chord is 221±16 µm s^{-1}, which agrees with a value previously reported for the endothelial P_{os}. The error due to the delay imposed by diffusion of sucrose across the unstirred layer is estimated as 10–15% after the initial 15 s, so that for the present transients which last several minutes extrapolation appears permissible. A solution of the diffusion–convection equation $\partial C/\partial t = D\partial^2C/\partial x^2 - Jv\partial C/\partial x$ for the semi-infinte case is $C_{(x,t)} = C_0/2\{\text{erfc}[(x-Jv.t)/2\sqrt{(Dt)}]+\exp(Jv.x/D).\text{erfc}[(x+Jv.t)/2\sqrt{(Dt)}]\}$, which for long times and comparatively small Jv tends to $C = C_0\exp(Jv.x/2D)$. 'Natural convection'[16] in the boundary layer also runs counter to diffusional delays.

These results reveal either a high conductance ($Lp = 114$ µm s^{-1}; steady-state $P_{os} = 115$ µm s^{-1}; P_{os} $(t = 0) = 166$ µm s^{-1}) or a low conductance (steady-state $P_{os} = 26$ µm s^{-1}), depending on the experimental conditions. The numerical values obtained for the high conductance are of a similar order of magnitude, suggesting that both hydraulic and osmotic flows could traverse the same high-conductance pathway. The dependence of steady-state P_{os} on $\Delta\pi$ could be explained by progressive 'recruitment' of the high-conductance pathway at the higher values of $\Delta\pi$. We speculate that a similar mechanism might have a regulatory role in physiological conditions.

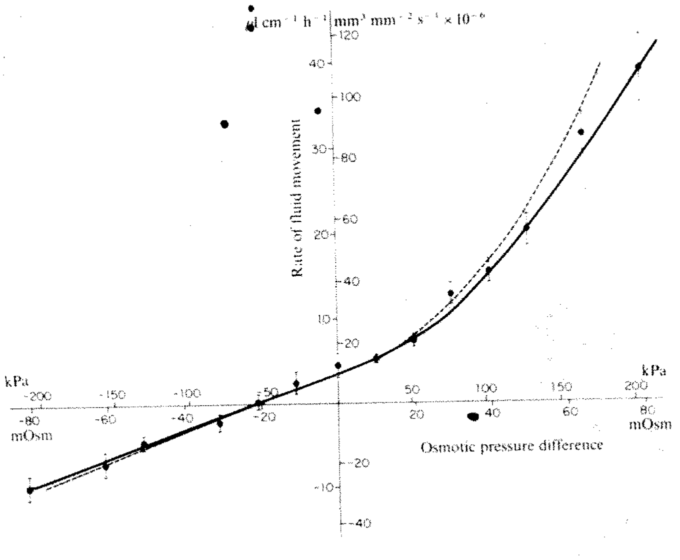

Fig. 3 Rate of transendothelial fluid movement induced by a difference in osmotic pressure. Average and s.e.m. values shown. The solid line was fitted by eye; the dashed line incorporates corrections for solute polarisation (the values for the limiting slopes or apparent P_{os} are 88 ± 6 and 25 ± 3 µm s^{-1} for the first and third quadrants, respectively; correction changes these values to 115 and 26 µm s^{-1}. Direction of fluid movements as above; positive osmotic pressure difference means aqueous hypertonic to stroma, and vice versa. The hydrostatic pressure difference was 10 cm H_2O.

The possibility that the intercellular junctions may be the site of this high-conductance pathway is supported by arguments from two lines of reasoning. In the first, if the junctions are assumed to be water-filled slits which allow laminar flow, one has: $Lp = a^3b/12\,\eta l$, where a is junctional width, b is $\frac{1}{2}$ total cell perimeter/unit area (10^3 cm cm^{-2}), η is viscosity of water (6×10^{-3} P) and l is length of junctions (1 µm). For an Lp of 114 µm s^{-1} (0.8×10^{-11} cm^2 s g^{-1}) the junctional width would be 39 Å. This figure is consistent with anatomical estimates (30–40 Å) and with the fact that horseradish peroxidase (estimated diameter: 45 Å) traverses these junctions[5].

In the second, if the junctions are assumed to be impermeable to water, the osmotic pathway would consist of the basolateral and apical cell membrane in series. If they are assumed uniform, from the P_{os} $(t = 0)$ value, the P_{os} for the cell membranes would be 200 µm s^{-1}. Although P_{os} values as high as this have been reported for erythrocytes[17], in the present framework the value found for the low conductance would be difficult to explain. For instance, a collapse of the intercellular spaces which would exclude the lateral membranes from the osmotic pathway would reduce the endothelial P_{os} to some 100 µm s^{-1}, rather than to the 26 µm s^{-1} found. On the other hand, if the high conductance is attributed to the intercellular junctions, the transition to low conductance can be explained either by flow, osmolarity and time-dependent variations in the apparent reflection coefficient of the junctions for solute, or by an actual change in their conductance. In the extreme in which osmotic flow through the junctions becomes small, the low conductance value found would correspond almost entirely to a P_{os} of 30 µm s^{-1} for the cell membranes. Such a value is of the order of those found for other animal cells[9] such as the "inner membrane' of frog skin epithelium[18] (24 µm s^{-1}), and for some types of lipid bilayers (19 µm s^{-1}) (ref. 19).

In summary, the possibility that the high-conductance pathway corresponds to the intercellular junctions whereas the low

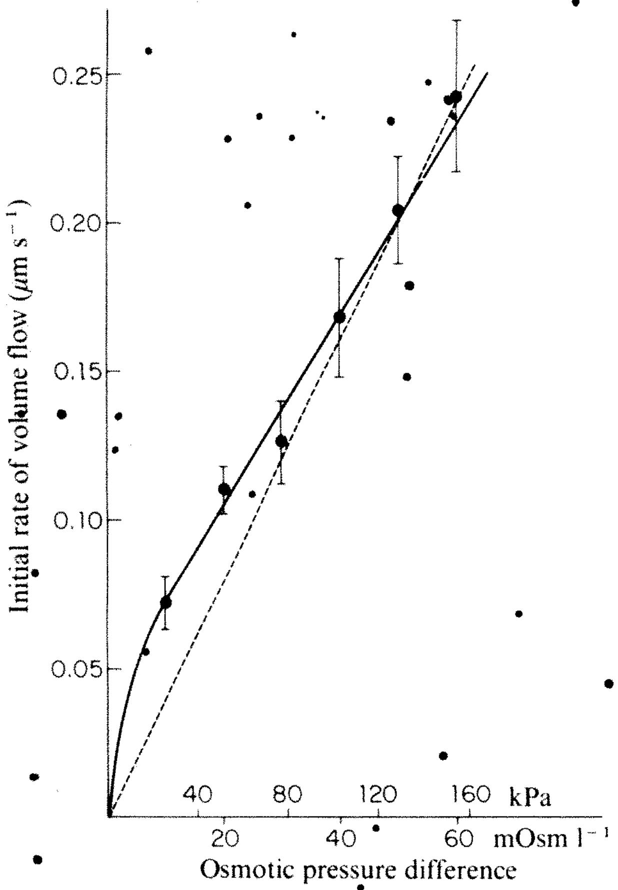

Fig. 4 Initial rates of osmotic flow (extrapolated at $t = 0$) plotted against the driving force. Average and s.e.m. values shown. The solid line was fitted by eye; the dashed line represents the chord. The basal rate of fluid transport superimposed (approx. 0.012 μm s^{-1}) was neglected. The hydrostatic pressure difference was 20 cm H_2O.

conductance reflects properties of the cell membranes seems consistent with the present results. The detailed role of each pathway in the fluid transport mechanism across this and other epithelia remains a central question.

This work was supported by NEI, USPHS grants to J.F. and by a Fight for Sight Student Fellowship to C.R.W. We thank Dr T. J. Pedley for pointing out the initial steps of the solution of the diffusion–convection equation, and Dr S. R. Williamson for useful suggestions.

Experimental model of ulcerative colitis

AN experimental animal model of human ulcerative colitis has long been required, as there is no model with an immunological basis available. We report here the induction of inflammatory ulcerative changes in rat colon mucosa, similar to those of human ulcerative colitis. The lesions were consistently obtained by an experimental procedure that induces specific adult anti-foetal tissue immunoreactivity.

Rat foetal colon implants beneath the renal capsule of syngeneic adult rats developed, by 6 d, acute inflammation and later ulceration of the mucosa morphologically indistinguishable from active ulcerative colitis. The subrenal capsular implantation method for organ growth employed has been used as a model of delayed hypersensitivity of murine small intestinal mucosa in an allogeneic system[1,2]. In the present experiments, the syngeneic implantation permitted survival of the colon implants which, although not rejected, showed continuing immunological inflammatory damage of the mucosa. It is possible that ulcerative colitis and presumably other autoimmune diseases of man may follow or be exacerbated by immunoresponsiveness to foetal antigens, which may re-emerge in adult tissues in certain pathological conditions[3].

The syngeneic rats were the Sprague–Dawley strain maintained in Monash University by brother–sister mating; they accepted tail skin syngeneic grafts but not allografts. Ten male (250 g) and ten female (190 g) rats received sub-renal-capsule implants of descending colon from 16–18-d-old foetal rats from two litters obtained by caesarean section of pregnant females of this inbred strain. Halves of each descending colon were implanted into male and female recipient pairs. A left lumbar approach to the left kidney of anaesthetised recipient rats was used in each case and the pairs of male and female recipients were killed at 48-h intervals, that is up to 20 d. The time scale of changes in the implanted colon was further investigated in five male and five female Sprague–Dawley rats which were killed in pairs 3, 5, 21, 28 and 32 d after implantation of colons from another litter of syngeneic foetal rats.

With the single exception of one rat after 28 d, the implanted syngeneic foetal colon remained structurally and functionally viable as shown by vascularisation by recipient blood vessels and continued production by the mucosa of intestine-specific mucin which stained positively by immunofluorescence with a specific anti-intestine serum[4], and also

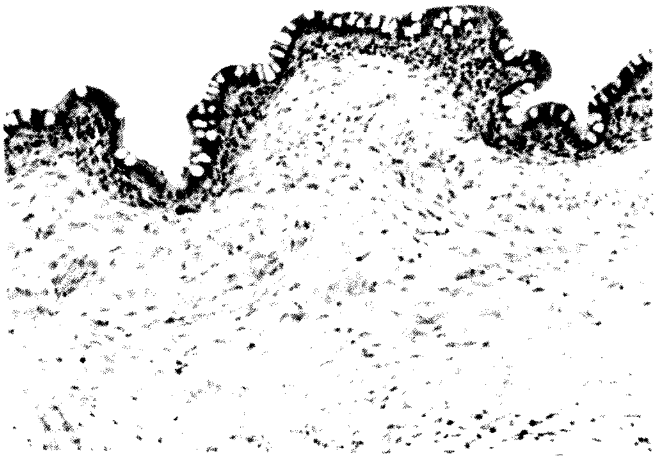

Fig. 1 Rat foetal colon implanted beneath renal capsule of syngeneic adult for 6 d. Note viable mucosa with prominent mucin droplets and a broad band of leukocytic infiltration beneath. (Paraffin section stained with haematoxylin and eosin; × 90.)

with periodic acid-Schiff and alcian blue (pH 2.8). After 6 d the graft (in both male and female recipients) had become infiltrated by lymphocytes and eosinophils (Fig. 1). By 12 d many plasma cells were present and the mucosa was ulcerated with an abundant infiltration by neutrophil granulocytes at the sites of ulceration; the lumen of the graft also contained collections of granulocytes and large quantities of mucin (Fig. 2). Gradually over the succeeding days, the mucosa became depleted of mucin-secreting cells, and by 20 d it was largely destroyed. These changes were found consistently in all the pairs up to d 20. At d 28, the implanted foetal colon in one rat was reduced to a fibrous sac; in the other 28-d rat the implanted colon was well preserved overall, showing as the only pathological change, a microscopic mucosal diverticulum invested by an abundant focal lymphoid reaction. In one of the rats killed on d 32, there was again good preservation of the implant with only microscopic ulceration, in the other 32-d rat, the implant showed advanced changes such as occurred in the 12–21 d experiments.

The sex of the foetal rats donating implants was not determined in the 15 rats from three litters used in the above experiments, but a sample from each rat was implanted into male and female adult pairs. The findings in both male and female pairs of recipients were usually similar and no systematic differences were observed. We concluded that the pathological changes in the colonic implants are not attributable to sex-related antigenicity. To examine the strain specificity of the response, five male and five female Sprague–Dawley rats were given sub-renal-capsule implants of DA rat foetal colon. All of these allogeneic implants were totally destroyed within 10 d of implantation.

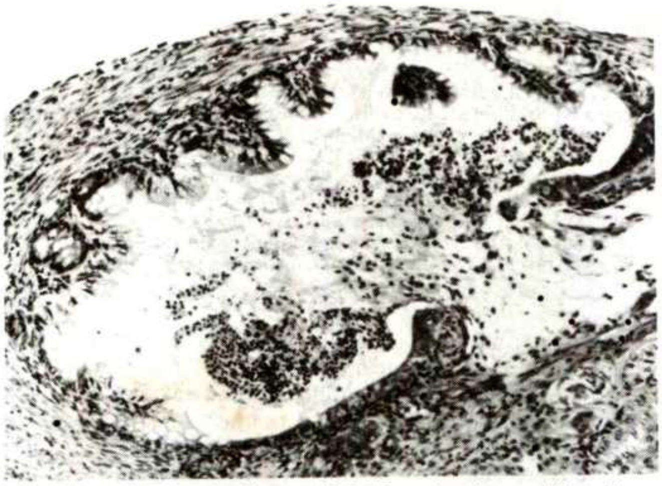

Fig. 2 Foetal colon implant at 12 d. Note ulcer lower right with conspicuous granulocytic exudate extending into lumen filled with mucin. Remaining mucosa looks viable but with less mucin production around the ulcer; it shows conspicuous submucosal leukocytic infiltration. (Paraffin section stained with haematoxylin and eosin; ×90.)

Serum samples from the majority of Sprague–Dawley rats 10 d after implanting syngeneic foetal colon, contained antibody reactive with foetal intestinal mucosa but not adult mucosa, as judged by indirect immunofluorescent staining[5] (Fig. 3). This indicates an immune reaction in the adult rats to foetal antigens deficient in the adult animal. Such a reaction has been demonstrated[6] by inoculating adult rats with syngeneic foetal intestinal material.

The lymphocyte and plasma cell infiltration and the serum antibody activity can be regarded as evidence of an immune response in the recipient to foetal antigens. The inflammatory and subsequent ulcerative reactions can also be attributable to immune rejection of foetal colonic mucosa and experiments to establish this are in progress.

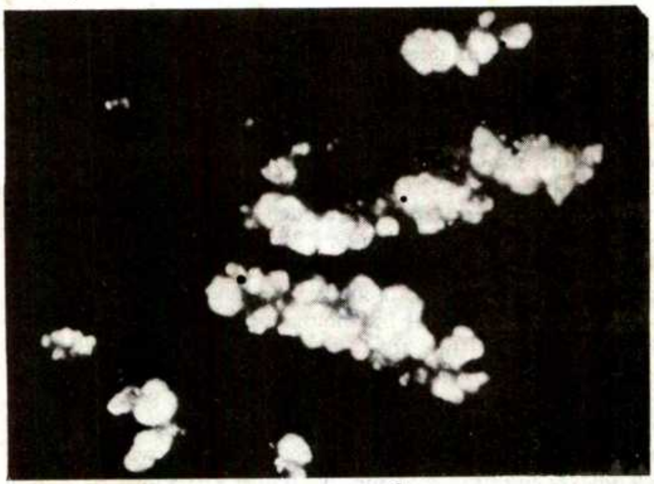

Fig. 3 Immunofluorescent staining of rat foetal colon mucosa by serum from adult rat implanted with foetal colon for 17 d. (Frozen section stained by sandwich immunofluorescence with fluorescein-labelled rabbit anti-rat-globulin, ×110.)

The morphological features of the lesions in the foetal colon implants are similar to those of human ulcerative colitis, which is also believed to have an immunological basis[7]. Patients with this disease have circulating lymphocytes which are cytotoxic to colon epithelial cells, and non-cytotoxic serum antibody directed against cytoplasmic components of colon epithelial cells. This rat system should provide a useful new model for investigating immunologically-determined colonic inflammatory disease. It will be interesting to see if it is possible to stimulate anti-colonic autoimmune activity in the recipient rats.

We thank Mrs J. E. McNaughtan and Mr S. L. Lewis for technical assistance. The work was supported by a grant from the NH and MRC.

K-contractures and membrane potential in mammalian skeletal muscle

A FUNDAMENTAL property of skeletal muscle fibres is the ability to develop tension in response to surface membrane depolarisation. The relation between membrane potential (V_m) and tension has been measured in amphibian muscle using external potassium concentration (K_0) to clamp V_m [1–4]. A K-contracture follows exposure to high K_0 and tension is graded with K_0 between 20 mM ($V_m = -50$ mV) and 50 mM ($V_m = -40$ mV). Human intercostal muscle, however, either does not respond mechanically to K_0 of 80 mM or gives a very small contracture[5]. It is not clear whether this is a result of diffusion delays in the large bundles of fibres or whether there is a basic species difference in excitation–contraction coupling. I report here that, in bundles of fewer than 20 fibres, the relationship between K-contracture tension and K_0 is shifted to higher K_0 in rat muscle because changes in K_0 are less effective in altering V_m.

Adult male rats were killed by ether anaesthesia. The soleus, extensor digitorum longus (EDL) or sternomastoid muscle was isolated; bathed in solution A (Table 1), and bubbled with 95% O_2 and 5% CO_2 during dissection at 20 °C. The sternomastoid has red and white segments and bundles of red or white fibres can be isolated[6]. Bundles were mounted in a rapid flow bath[7] at 37 °C. One tendon was fixed to an RCA valve and isometric tension recorded on a Grass Polygraph pen recorder. Twitch tension was 2.5 and 2.8 kg cm^{-2} in two sternomastoid bundles (cross-sectional areas measured after fixation for electron microscopy). The tetanus to twitch ratio was between 4:1 and 5:1 in whole muscles and small bundles. Similar bundles from toad (*Bufo marinus*) semitendinosus muscles, in amphibian Ringers[7] at 20 °C were also used.

Records from mammalian bundles exposed to 80 mM K_0 are shown in Fig. 1. Neither EDL (Fig. 1*a*) nor white sternomastoid (Fig. 1*c*) gave contractures although twitch tension fell quickly and recovered after the return to 3.5 mM K_0 within 30 min (EDL) to 1 h (white sternomastoid) without potentiation. Contractures from soleus (Fig. 1*b*) and red sternomastoid (Fig. 1*d*) bundles rarely exceeded twitch tension. Recovery of twitch tension in normal solution took 10 min (red sternomastoid) and 30 min (soleus) and was followed by potentiation. In the same system toad semitendinosus bundles gave contractures of four and nine times twitch tension with typical plateau and spontaneous decay phases. Recovery of twitch tension took 3 min in normal solution and was followed by potentiation. Clearly the responses of mammalian and amphibian bundles to 80 mM K_0 are significantly different, and rat mucles have a response similar to that reported for human intercostal muscle.

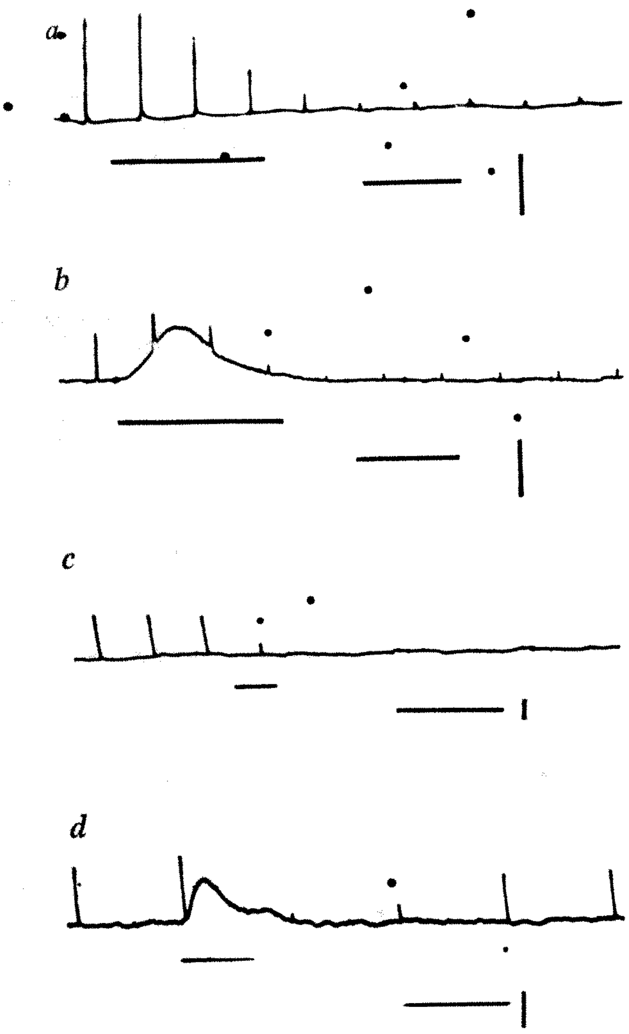

Fig. 1 Tension during exposure to 80 mM K_0 (Solution B, Table 1) for a period indicated by the horizontal bars under each record. *a*, EDL; *b*, soleus; *c*, white sternomastoid; *d*, red sternomastoid. Rapid vertical deflections are twitches (direct electrical stimulation). Scale: tension, vertical bar, 50 mg; time, horizontal bar, 20 s (*a* and *b*) and 60 s (*c* and *d*).

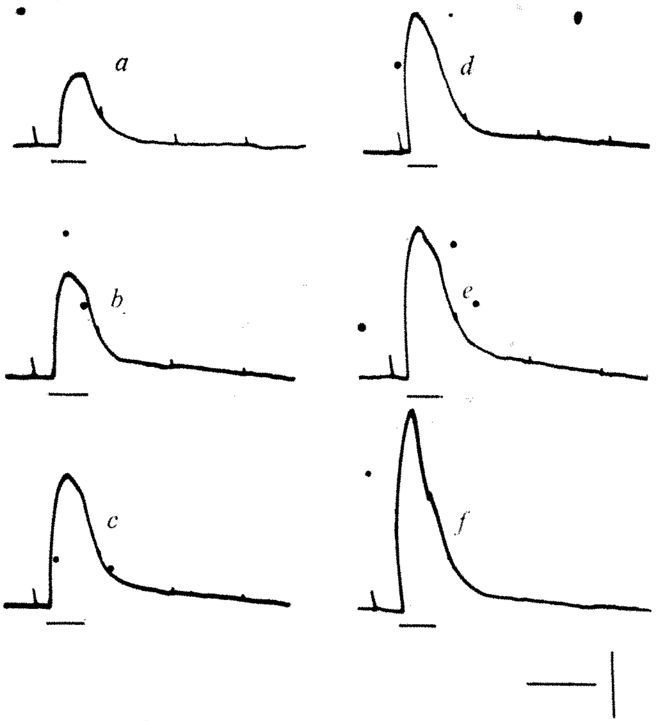

Fig. 2 Contractures from a bundle of red sternomastoid fibres exposed to different K_0 for a period indicated by the horizontal bars under each record. *a* 90 mM K_0; *b* 112 mM K_0; *c* 135 mM K_0; *d* 158 mM K_0; *e* 180 mM K_0; *f* 200 mM K_0. 45 min was allowed between contractures. Test solutions of K_0 up to 180 mM were made with appropriate proportions of solutions C and D (Table 1). Solution E was used for K_0 of 200 mM. The external chloride concentration was kept constant so that the K×Cl product varied. Scale: tension, vertical bar, 100 mg, time, horizontal bar, 60 s.

The responses (Fig. 1) seem to fall into two groups according to fibre type. The EDL contains mostly white fibres[7,8] and its response was similar to that of the white sternomastoid. The soleus, which contains mostly red fibres, responded in a manner similar to that of the red sternomastoid. Comparison of responses with twitch speed gave no consistent relationship since red and white sternomastoid bundles had similar contraction times and were five and ten times faster than the EDL and soleus respectively.

The smaller K-contracture in mammalian muscle was investigated further in red sternomastoid fibres by examining peak contracture tension and V_m when K_0 varied from 3.5 to 200 mM. The solutions were hypertonic for K_0 greater than 120 mM and so test and control solutions of 468 mOsm were used to avoid transient effects of tonicity on tension[10,11]. Twitch tension fell by 80% or more in the hypertonic control solution while tetanic tension fell by 10% so that the tetanus to twitch ratio was 20:1.

Table 1 Solutions used

	Concentrations (mM)*		
Solution	Na	K	Cl
A	165	3.5	174.5
B	88.5	80	175.5
C	206	3.5	216.5
D	28	180	215.5
E	28	200	235
F	28	220	255

*In addition each solution contained glucose 11 mM, Ca 2.5 mM, Mg 1.0 mM, HCO_3 25 mM and HPO_4 3.0 mM.

K_0 up to 200 mM induced no contracture in white sternomastoid bundles. Contracture tension in red sternomastoid bundles increased with K_0 (Fig. 2). Tension in 200 mM K_0 (Fig. 2*f*) was 10 times twitch tension but less than tetanic tension. Greater contracture tension might have been recorded if K_0 above 200 mM had been used. Toad bundles developed maximum tension with 30–60 mM K_0. Higher concentrations (up to 120 mM) increased the rate of tension development, reduced plateau duration and increased the rate of spontaneous relaxation. Similar results have been reported for single frog fibres[1,12,23]. The kinetics of mammalian contractures (Fig. 2) showed a similar dependence on K_0. Tension in high K_0 was shifted to higher K_0 in mammalian muscle. This can be explained by a change either in the relation between tension and V_m or in the relation between V_m and K_0.

V_m was recorded in red sternomastoid fibres using intracellular microelectrodes filled with 3 M KCl and the average resting V_m was -65 ± 1.5 mV. The steady-state V_m (after 3 min.) is plotted against log K_0 in Fig. 3: the line through the points has a slope of 28 mV, less than expected for a potassium electrode (61.5 mV) and less than reported for amphibian fibres (45 mV) with the same concentrations. The hypertonic conditions are not responsible for the observed slope, for points recorded in normal solutions fit the same line. The reduced slope would shift tension to higher K_0 in mammalian muscle.

The time course of depolarisation of red sternomastoid fibres in high K_0 was surprisingly slow, taking 3 min, with a half time of 20–30 s, while repolarisation in 3.5 K_0 took 30 min. The time course was even longer in white sternomastoid fibres. But toad semitendinosus fibres, from bundles of a similar size, took 2 s to depolarise from -80 to -60 mV in 20 mM K_0 with a half time of 4–5 s. It seems unlikely therefore that the time course of V_m in mammalian fibres is an artefact.

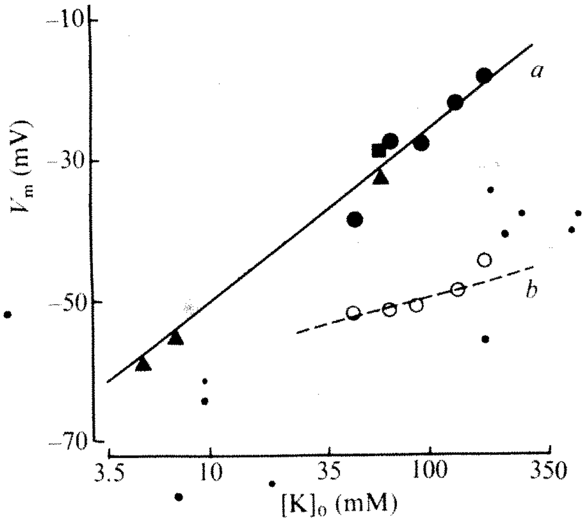

Fig. 3 V_m, in mV, as a function of the logarithm of K_0 in mM. ○, V_m20; ●, steady-state V_m from the same fibres. Each point is the average of three or four fibres and contains the standard errors. Tetrodotoxin (2×10^{-8} g ml^{-1}) prevented action potentials and twitches. Bundles were stretched to 1.8 times rest length to reduce contractures. The fibres were equilibrated in hypertonic solutions for 1 h before the experiment. ■, fibres in isotonic solutions. Curve *a* was drawn through the points by eye and line *b* was drawn through the V_m20 points assuming the relation between V_m20 and log $(K)_0$ is linear.

The relation between tension and K_0 may be shifted to higher K_0 by the reduced rate of change of V_m if depolarised mammalian fibres are subject to contractile inactivation in the same way as amphibian fibres[1,3]. Spontaneous contracture relaxation (Fig. 2) suggests inactivation, so that tension may be inhibited before the steady-state V_m is achieved. Maximum tension was reached within 20 s (Fig. 2) and is therefore a function of V_m 20 s after the solution change (V_m20). V_m20 is plotted against log K_0 in Figure 3 and is less than 50% of the steady-state V_m.

The reduction in K-contracture tension in mammalian muscle is a combined effect of the small change in the steady-state V_m and the slow time course of depolarisation following exposure to high K_0. In 80 mM K_0 mammalian fibres respond to a V_m20 of -51 mV while amphibian fibres respond to a V_m that quickly approaches -30 mV, a potential considerably more positive than the contracture threshold. The relation between tension and V_m in mammalian fibres is shown in Fig. 4. Comparison with data from ref. 1 (see Fig. 4) shows that the true relation between tension and V_m is similar in mammalian and amphibian skeletal muscle.

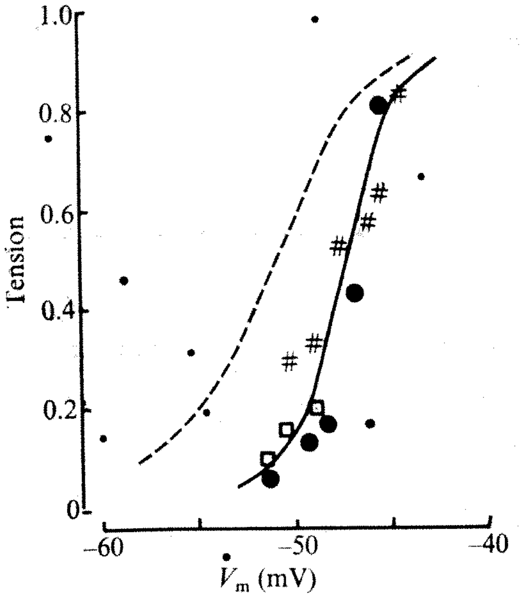

Fig. 4 Tension (in relative units) as a function of V_m in mV. V_m was taken from V_m20 (line *b* in Fig. 3). The symbols are peak tension during K–contractures and records taken from one bundle have the same symbol. The solid line was drawn by eye. The broken line is for amphibian skeletal muscle, ref. 1.

What are the reasons for the slope of 28 mV relating V_m to log K_0 and for the slow time course of V_m changes in sternomastoid fibres? The 28-mV slope (Fig. 3) indicates that another ion contributes to V_m. This is probably not sodium because the resting sodium permeability is low and ouabain (10^{-4}M) does not alter V_m in 60 min. The ion is probably chloride. Concentrations of chloride are not in equilibrium with the resting V_m in several preparations[14–17] and I have found that replacement of external chloride by sulphate increases the average resting V_m in sternomastoid fibres from -64 mV to -76 mV and increases the slope of the line relating V_m to log K_0 to 44 mV. The slow time course of V_m is unlikely to result from diffusion delays for reasons given above. 'Creep' arising from ion depletion in the T tubules[18,19] was recorded and is greater in mammalian fibres than in amphibian fibres with a time constant approximately 10 times longer. Restricted diffusion into the T tubules would increase the time course of changes in V_m.

Thus, bundles of mammalian fibres develop less tension in high K_0 than bundles of amphibian fibres. The true relation between tension and V_m is similar in the two species but the relation between V_m and K_0 for a given change in K_0 is different in two respects; first the change in V_m for a change in K_0 is 40% less in mammalian fibres and second the rate of change of V_m after an increase in K_0 is more than 10 times slower.

I thank Professor P. W. Gage for facilities and helpful

discussion, and the Muscular Dystrophy Associations of America for a grant.

Synthesis of phospholipids and membranes in prebiotic conditions

IT is generally agreed that stable membranes were prerequisite to the assembly of the earliest self-replicating systems[1–4]. Phospholipids, which are ubiquitous in biological membranes and which self-assemble in aqueous environments into stable lipid bilayers and vesicles[4], are obvious candidates for prebiotic membrane components. We report here the abiotic synthesis of various lipids, including membranogenic phospholipids.

Our rationale in establishing simulated primaeval conditions included considerations of possible precursors, energy sources, catalysts and the behaviour and stability of the reactants and products. Derivatives of 1,2-diacylglycerophosphate are common membrane lipids, suggesting fatty acids, glycerol and phosphate as precursors. Heat derived from the Sun was a major primaeval source of energy[5], and recent evidence indicates that average temperate zone surface temperatures may have reached 70 °C before 3×10^9 yr ago[6]. The abiotic synthesis of polypeptides (molecular weight>1,600) at 65 °C, in the absence of water or catalysts, has been detected in amino acid mixtures after incubation times of 40 d (ref. 7); we selected similar conditions for our experiments. Although various clays such as kaolin (an aluminum silicate) have been found to promote condensation reactions in aqueous conditions[8,9], this mineral is rare in Precambrian sediments[10]. However, silicon oxide or silica is present in nearly all rocks[11], and silicate rocks have been shown to promote condensations in certain conditions[12]. We tested the catalytic properties of silicic acid (silica gel H) and kaolin as possible models for natural silica-containing sands and clays. (Since completing this work, we have learned that washed and ignited sea sand promotes polypeptide formation when heated with mixtures of amino acid[13].) Dicyanamide has been widely used as a possible prebiotic condensing agent, and as it has been shown to catalyse glycerol phosphorylation in acid solutions[5], it was included in some experiments. Our general rationale was that tide pools containing dilute solutions of glycerol, phosphate and cyanamide, and having surface films of various hydrocarbon derivatives, could evaporate and produce mixtures of hydrophobic and hydrophilic compounds within a hot sand or clay matrix.

To synthesise neutral lipids, ^{14}C-glycerol and various C12 lipids were mixed in duplicate vessels and the solvent was

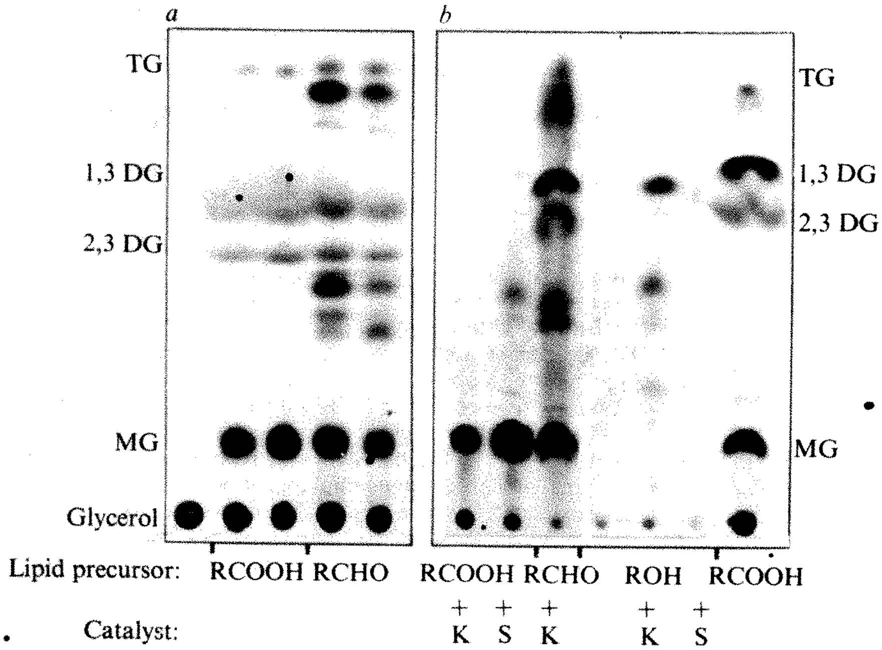

Fig. 1 Autoradiograms of ^{14}C-glycerolipids including mono- (MG), di- (DG), and triglycerides (TG). 50 nmol ^{14}C-glycerol (2×10^6 d.p.m., ICN, Irvine) and 250 nmol C12 acid (RCOOH, Sigma), alcohol (ROH, Sigma), or aldehyde (RCHO, Aldrich) were placed in autoclaved microreaction vessels with loose fitting screw tops. In some cases, 10 mg kaolin (K, J. T. Baker, Phillipsburg) or silica gel H (S, Sigma), prewashed with acetone and chloroform–methanol, was added to the vessel before the removal of the organic solvent by vacuum. Reaction vessels containing aldehyde were sealed individually in small plastic canisters flushed with argon and containing a few $CaCl_2$ pellets. In one experiment using fatty acid and fatty alcohol, open test tubes were used, without desiccant (reactants were suspended in H_2O which was evaporated during the first 2–3 d of incubation). Lipid yield from fatty acid was indistinguishable from the experiment using vacuum-evaporated microreaction vessels. After 1 week at 65 °C, total lipids were extracted in chloroform–methanol or ethyl ether and chromatographed on thin-layer plates of silica gel (F-254; EM Lab., Elmsford) twice in hexane–ethyl ether–acetate (100 : 200 : 1) (Fig. 1*a*), or once in a more complex solvent system[20] followed by the first solvent (Fig. 1*b*). Autoradiography was performed with Kodak RP-Royal X-omat film; exposure times of 3–7 d at −85 °C were followed by development in Diafine. One week exposure revealed 50–100 d.p.m. ^{14}C. Standard lipids were monolaurin (Sigma), dilaurin (Supelco, Bellefonte) and trilaurin (Sigma), run as internal standards in some samples and adjacent to unknowns in some cases. Identification of unknowns is tentative, as it is based solely on TLC R_fs in several solvent systems (some samples were eluted and rechromatographed). Glycerol and lipids were used as received, except the aldehyde, which was purified on silicic acid in hexane and stored under argon.

removed by vacuum or by evaporation during subsequent incubation at 65 °C. Relatively short chain, saturated lipids were used as precursors for glycerolipids because they are fluid at 20–46 °C and are not labile to oxidation within the chain. In some cases, prewashed kaolin or silicic acid was added before the removal of the solvent. After drying, all samples were incubated for 1 week. Lipids were extracted and chromatographed on thin-layer plates of silica gel, placed over X-ray film for autoradiography, and the radioactive spots were scraped for scintillation counting. Typical autoradiographic patterns are shown in Fig. 1. Glycerol incubated alone showed only a single spot at the origin. Monoglyceride was the major reaction product from fatty acid, and was also prominent in the fatty aldehyde samples. Also tentatively identified were 1,3- and 1,2-diglycerides, and small amounts of triglycerides and several unknown lipids, possibly long chain cyclic acetals of glycerol. Total yields of glycerolipids were 3.1% from fatty acid and 7.7% from fatty aldehyde. Fatty alcohol formed little, if any, monoglyceride or other glycerolipid in the absence of added agents. With kaolin, however, detectable amounts of labelled lipids (0.2% yield) were formed.

Figure 2 compares the net yield of labelled lipid in the presence and absence of kaolin and silica gel. Surprisingly, kaolin seems to inhibit the formation of labelled lipids from fatty acid, but has much less effect on the reactivity of glycerol–fatty aldehyde. Silicic acid promotes the formation of monoglycerides from fatty acid (3.8% yield compared to 1.8% yield without catalyst), but inhibits the synthesis of more complex glycerolipids.

As initial experiments suggested that monoglycerides and more complex glycerolipids could have accumulated in evaporated tide pools, we selected an ether monoglyceride (chimyl alcohol) as a precursor for phospholipids. Ether monoglyceride is stable in the conditions used and avoided the requirement for large amounts of glycerol and fatty acid in the samples. Silicic acid, kaolin and dicyanamide were tested as possible condensing agents. Duplicate samples containing ether monoglyceride, dodecanoate and prewashed silicic acid and kaolin were mixed by vortexing in 2 ml H_2O containing phosphate (20 mM) and glycerol (6.5 mM), or sodium dicyanamide (50 mM), or both (Table 1). All tubes were incubated sealed, for 12 h at 65 °C, then all but one pair were allowed to evaporate to dryness in the vented oven. After 2 d the open tubes were completely dry in appearance and, after another 7 d, all tubes were extracted with chloroform–methanol–0.1 M KCl (ref. 14). Polar lipids were precipitated from acetone and chromatographed on thin-layer plates.

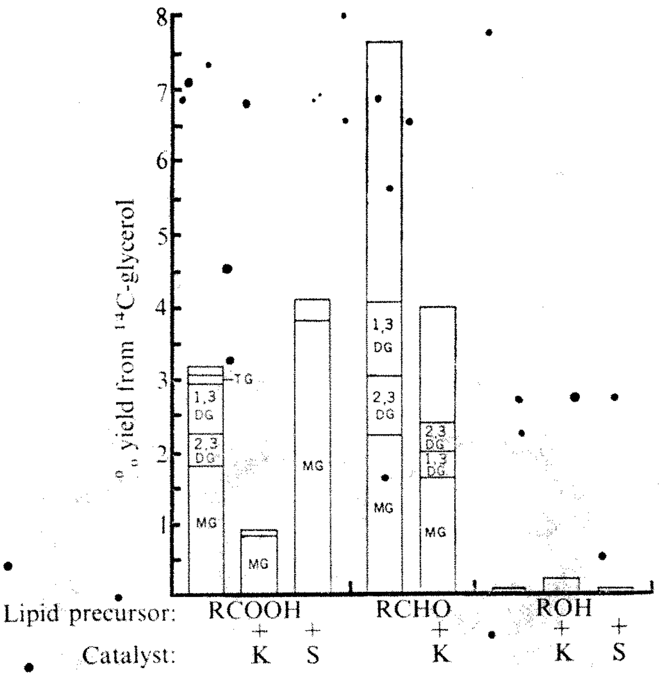

Fig. 2 Quantitation of ^{14}C-glycerolipids from C12 acid (RCOOH), aldehyde (RCHO) and alcohol (ROH). Radioactive lipids detected by autoradiography were scraped from TLC plates into scintillation vials. One ml H_2O was added and after 1 h, 5 ml cocktail ('Tritosol' modified from Fricke[21]) was added. Percentage yield is based on estimated initial 1.8×10^6 c.p.m., though total c.p.m. recovered from samples free of K and S were substantially lower, due to vaporisation of glycerol and adsorption to containment canister when present. RCHO samples contained substantial amounts of apparent triglycerides, but it was not feasible to count these spots separately from large amounts of an unknown lipid running just below. Unlabelled sections of bars in all other cases represent unidentified compounds.

The polar lipid fraction from sample 2 (Table 1) contained phospholipids with R_fs similar to phosphatidic acid (PA), phosphatidyl glycerol (PG), and phosphatidyl glycerophosphate (PGP), and some residual neutral lipids. Total yield of lipid phosphorus was 0.2% of the phosphate in the reaction mixture. Samples 1 and 4 each yielded <0.015% lipid phosphorus, suggesting that dicyanamide and evaporation together enhanced phospholipid synthesis more than tenfold. Several polar lipid-like compounds (ninhydrin negative) were present in sample 3, but no phospholipids were found.

To determine if the partially purifield phospholipids could form membranes, an aliquot from the polar fraction of

Table 1 Synthesis of phospholipid. All samples contained ether monoglyceride (chimyl alcohol, 10 mg, Sigma), dodecanoate (10 mg), prewashed K (50 mg), prewashed S (50 mg), and sodium azide (0.01% initial concentration). When present, phosphate was 20 mM Na_2HPO_4, *p*H 7.8, glycerol was 6.5 mM, and sodium dicyanamide (Aldrich) was 50 mM. Lipids extracted from alkaline samples after addition of 0.1 M KCl (ref. 14) were only partly soluble in chloroform (C) or ethyl ether (E), but readily soluble in C–methanol (M) (2 : 1). Polar lipids were precipitated by adding 10 volumes of acetone to 1 volume of C–E (1 : 1) containing partially solubilised lipid and storing at −20 °C overnight. Insoluble (polar) lipids were collected after centrifugation in a clinical centrifuge at 4 °C. Phospholipid was identified by spray reagent[22] and by the method of Lowry *et al.*[23] after scraping spots from charred preparative plates of silica gel H run in C–M–H_2O (65 : 25 : 4). Compounds similar to PA, PGP and PG were present at greater than 0.065, 0.016, and 0.005 μmol lipid phosphate in the acetone fractions of sample 2. Samples 1 and 4 each contained less than 0.006 μmol total lipid phosphorus.

Sample	Treatment	Phosphate	Glycerol	Dicyanamide	Phospholipid detected
1	Aqueous	+	+	+	Trace
2	Evaporated to dryness	+	+	+	0.2% Yield
3	Evaporated to dryness	—	—	+	None
4	Evaporated to dryness	+	+	—	Trace

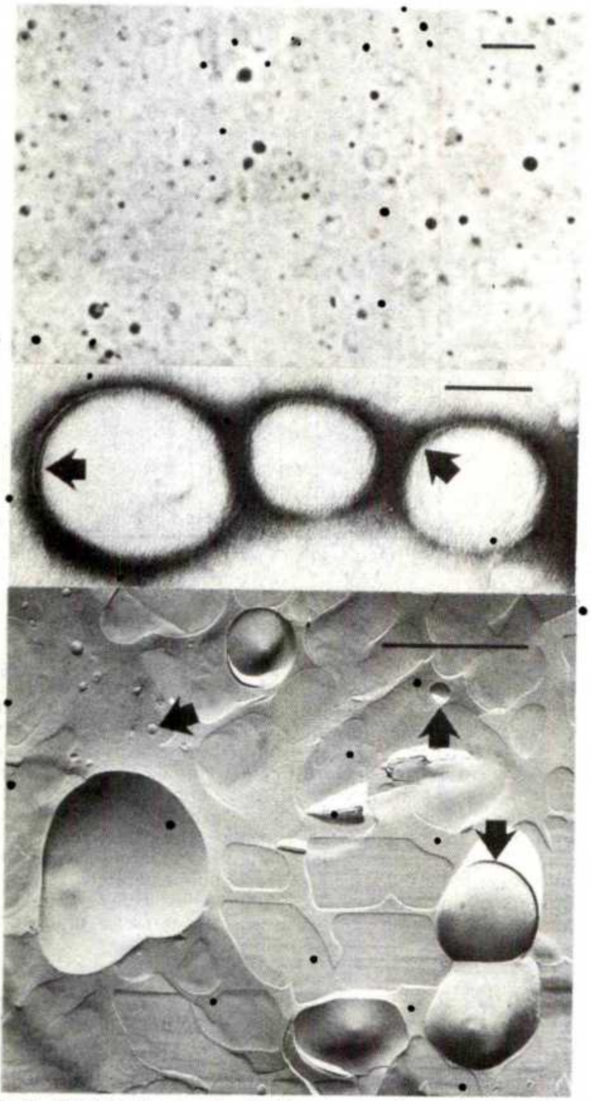

Fig. 3 Vesicles from polar lipid extracts of sample 2. *a*, Phase contrast micrograph (bar is 10 μm) of lipid suspension (1 mg ml^{-1}, made by evaporating solvent from aliquot in small tube, adding 30 mM NaCl, 2mM Na_2HPO_4 (*p*H 7.4), and warming to 50–55 °C for 1 min. *b*, Negative stain electron micrograph (bar is 0.1 μm) of above preparation after probe sonication (Bronwill Biosonik, Will Corp., Rochester, New York) for 10 s at 53 °C. Vesicles were stained with uranyl acetate (1 %) after sample was applied to carbon–formvar coated grid and blotted dry. Note several lamellae (arrows). *c*, Freeze-fracture electron micrograph (bar is 1.0 μm) of lipid suspension (5 mg ml^{-1}) made by warming lipid film as above with the buffer containing 25 % glycerol as a cryoprotectant. Note vesicles of various sizes (arrows).

sample 2 was dried in a small tube. The sample was suspended in 30 mM NaCl, 2 mM Na_2HPO_4 (*p*H 7.4) by warming to 50 °C in a water bath. After a few seconds, a slightly opalescent solution with no visible particles was obtained. Phase contrast microscopy revealed a heterogeneous suspension of apparent vesicles (Fig. 3*a*). Brief sonication with a probe sonicator at 50–55 °C resulted in a more homogeneous population of vesicles (negative stain electron micrograph, Fig. 3*b*). A concentrated suspension, made without sonication in the above buffer containing 25% glycerol, was prepared for freeze-fracture electron microscopy. This technique exposes the hydrophobic plane of lipid bilayer membranes and preserves the structure of lipid–water phases[15]. The presence of lipid vesicles of various sizes in this preparation (Fig. 3*c*) confirmed our light microscope and negative stain electron microscope observations.

This work has implications concerning the possible origin of life on Earth. Although considerable progress has been made in the abiotic synthesis of important biomolecules, including phospholipid precursors, in simulated primaeval conditions[5,16], the only similar studies of prebiotic glycerolipid synthesis are those of Degans *et al.*[8,9], who reported the synthesis of neutral lipids from glycerol and fatty acids in a water–kaolin mixture held at 85 °C for 2 weeks. Neither reagent purity nor control experiments were described, however, and yields were relatively small (about 0.1%). Our results show that both fatty acid and fatty aldehyde react rapidly with glycerol in the absence of catalysts to form the precursors of membrane lipids, and that phospholipids and lipid-membrane vesicles can assemble in possible prebiotic conditions. We suggest that silicates other than kaolin are likely to have promoted such syntheses.

It is significant that phosphatidyl glycerol was apparently formed in our reaction mixture. This lipid, and its aminoacyl derivatives, are prominent in most prokaryotic membranes[17]. Our results show that membrane-forming lipids require only three precursors: glycerol, fatty acid or aldehyde, and phosphate. An alternative and well-studied model system for prebiotic membranes consists of proteinoid 'microspheres', prepared from concentrated solutions of amino acid polymers[18]. There is general agreement, however, that biological membranes require lipid bilayers as barriers to free diffusion of metal ions and substrate molecules. Because our results show that membranogenic lipids are readily produced in simulated prebiotic conditions, we concur with suggestions (Goldacre in ref. 4)[3,4,19] that lipid bilayer membranes could have been present before the accumulation of proteins, polynucleotides and other complex molecules.

This study was supported by a grant from the NSF. W.R.H. was supported by a UC Regents Fellowship and an Earle C. Anthony Fellowship in Zoology.

The Science Dictionaries

Three useful and up-to-date works of reference intended not only for students, teachers and researchers but also for science journalists and the general reader.
Each book is designed for easy use – entries are arranged alphabetically and defined under the most common form of term, with synonyms in brackets. S.I. units are used throughout and all entries are thoroughly cross-referenced.

A Dictionary of Life Sciences

E. A. Martin

The recent trend to treat the biological/life sciences as a whole rather than divided into separate units is reflected in this concise dictionary which brings together in one volume all the main branches of zoology and botany. Selected terms in related fields of biochemistry, endocrinology, animal behaviour and palaeontology are also included. All major plant and animal classes are fully described as well as the more important orders, and common names of animals and plants are cross-referenced to their appropriate taxonomic groups.

1976 £5.95 392pp

A Dictionary of Earth Sciences

Stella E. Stiegeler

The subjects covered here include geophysics, structural geology, geomorphology, oceanography, stratigraphy, palaeontology, sedimentology, climatology, meteorology, soil science, cartography, mineralogy, petrology and surveying. The terms defined reflect the recent modification of traditional concepts and the resulting development of terminology in the earth sciences. In soil science, for example, a new system of classification is now in in use, with a completely new terminology for the soil orders.

1976 £5.95 320pp

A Dictionary of Physical Sciences

John Daintith

This book covers the main branches of physics, chemistry and astromony – from Abbe condenser to zoom lens and zwitterion. A selection of relevant terms from the related fields of electronics, computer science and mathematics is included. Full accounts are given of the properties and uses of the chemical elements and many of their compounds. All the chemical terminology used is that recommended by the International Union of Pure and Applied Chemistry.

1976 £5.95 352pp

VOLUME 2

ESSAYS IN MEDICAL BIOCHEMISTRY

Edited by V. MARKS and C. N. HALES

187 pp. £4.00 (US $8.00) by surface mail to overseas addresses

Volume 2 of *Essays in Medical Biochemistry* continues the practice established in the first of providing, in readable form, highly authoritative but personal reviews of topics that are of general interest to medical biochemists. The subjects chosen for review are those that have undergone growth as a result of major conceptual and technological advances, and include essays by acknowledged world experts on complement, trace metals, acquired disorders of haem synthesis and chronobiochemistry.

List of Contents and Authors:

The Human Complement System: Biochemistry, Biology and Pathobiology
By D. T. Fearon and K. F. Austen

The Clinical Value of Trace-Metal Measurements
By H. T. Delves

Acquired Disorders of Haem Synthesis
By G. H. Elder

A New Perspective: Chronobiochemistry
By H. W. Simpson

Still Available:

ESSAYS IN MEDICAL BIOCHEMISTRY VOLUME 1
131 pp. £2.00 (US $5.00)

Announcing

Toxicology letters

An International Journal providing a forum for original and pertinent contributions in toxicology research.

Managing Editor:
A. WORDEN, Huntingdon Research Centre, Huntingdon, Cambs. PE18 6ES, U.K.

Aims and Scope
Toxicology Letters will provide the means for the publication of short papers that are considered by the Editors to be important to the advancement of Toxicology. It will cover, the following areas:
the experimental toxicity of pharmaceutical, surgical, food, tobacco, agricultural and industrial products
the investigation of environmental hazards to man, domestic animals and wildlife.
reproduction toxicity
mutagenicity
carcinogenicity
metabolism
safety assessment
clinical and veterinary toxicology
behavioral toxicology

Editorial Board:
K.S. LARSSON, *Stockholm, Sweden.* D. LORKE, *Wuppertal, W. Germany.* D.B. MENZEL, *Durham, North Carolina, U.S.A.* F.W. OEHME, *Manhattan, Kansas, U.S.A.* I.F.H. PURCHASE, *Macclesfield, U.K.* H.J. SCHUMACHER, *Jefferson, Arkansas, U.S.A.* S. TAKAYAMA, *Tokyo, Japan.* H. TUCHMANN-DUPLESSIS, *Paris, France.* G. ZBINDEN, *Zurich, Switzerland.*

1977 - Volume 1 in 6 issues - issue No. 1 scheduled for mid - 1977
Subscription Price: US $50.75/Dfl. 124.00 including postage

Specimen copies are available upon request from the Publisher.

Please mention this advertisement in your enquiry.

Journals are automatically sent by air to the U.S.A. and Canada at no extra cost and to Japan, Australia and New Zealand with a small additional postal charge.

Student books supplement

Recommended reading

During the past few years several publishers have produced series of books or pamphlets on specialist topics designed for use on undergraduate courses, particularly those in biological disciplines. Seven reviewers with experience of teaching such courses present here their impressions of the extent to which these series have been successful, in their particular fields, as additional teaching material for students.

THERE was a time when individual authors were able to write encyclopaedic works about their subject, and they frequently conveyed their information with an air of bland authority. In botany, names such as Sachs, Strasburger, Kerner and Oliver will generate waves of nostalgia among the older generation of plant scientists. In the early decades of this century, undergraduate courses could be taught using just one or two major texts as background reading. Modern single-author textbooks are usually far more restricted in the topics they cover and rarely claim to summarise all knowledge concerning that subject, more often they are content to illustrate the basic principles of their subject by reference to specific examples.

There have been some attempts at the encyclopaedic approach even in recent years, but such efforts have not been greeted with enthusiasm by the academic world. In these days of intense specialisation the experts in each of the topics covered are sure to find fault with the section dealing with their pet topic in any such book. And, since no student will read a textbook from cover to cover, if they cannot have certain sections specifically recommended, they are unlikely to pick up the book at all.

Multi-author books, sometimes with one or two editors involved in their production, represent one answer to the publisher's dilemma. Such books are often very successful, but may suffer from an uneven style and quality. An alternative is the series of monographs, each written by a specialist in the field, and each relatively independent of the others This overcomes inconsistencies in style and permits a relatively low cost for each volume. This approach has been taken by many publishers both at research and at undergraduate levels. Pioneers in the undergraduate biology sphere have been Edward Arnold (London), publishers of the *Studies in Biology* series (hardback and paperback editions).

Overall, this series has probably been more successful than any other which has been attempted. The secret of its success lies in the publisher's skill in the selection of topics and determination of length (and, thereby, cost). For example, the first issue of the series was *Ecological Energetics* by John Phillipson (£2.25, 95 pence) and this has become a classic of ecological literature within its ten years of life. The topic is sufficiently well defined to be outlined in about fifty pages and has been admirably condensed by the author. Similarly successful issues have been *Plants and Water* by J. Sutcliffe (£1.30 paperback), *Population Dynamics* by M E. Solomon (£2.20; £1.10), and *Photosynthesis* by D. O. Hall and K. K. Rao (second edition, March 1976; £2.80; £1.40). It is difficult to avoid the temptation to produce broad topic books—such as *Biology of Pollution* by Kenneth Mellanby (£1.75; 75 pence) and *Microecology* by J. L Cloudsley-Thompson (paperback £1.20)—which may do well on the bookstalls because of their general appeal, but which try to cover too great a scope to be valuable as course texts. The opposite end of the spectrum is also to be found in the series, particularly in the later issues (are the publishers running short of ideas or authors?). This extreme is represented by topics which are concise to the point of having limited appeal, such as *The Biology of Eucalypts* by L. D. Pryor (£3.20, £1.60) and *The Secretion of Milk* by Ben Mepham (£2 80; £1.40).

Plant Taxonomy by V. H. Heywood (£2.60; £1 30) has now entered a second edition (1976) and forms a useful introduction to experimental taxonomy. It contains some interesting chapters on chemical and numerical approaches to the subject which help to dispel the old-fashioned image of this subject. *Genetics and Adaptation* by E. B. Ford (£2.60, £1.30) is a new issue which is bound to sell well. The basic genetics are dealt with in two short chapters and the remainder of the book has a distinctly ecological flavour, dealing with such subjects as selection, melanism and isolation. This should be widely recommended as a background to a variety of biological courses, all first-year biology students should read it.

Tissue culture is now a frequently used technique with which most advanced level school biologists will have had some contact. *Plant Tissue Culture* by D. N. Butcher and D. S. Ingram (£3; £1.50) provides a guide to the implications and applications of the technique and also supplies the practical information needed for setting up simple tissue culture experiments in the laboratory.

Two more specialised studies which have been issued during the past year are *Phytochrome and Plant Growth* by R. E. Kendrick and B Frankland (£3; £1 50) and *Lichens as Pollution Monitors* by D. L. Hawksworth and F. Rose (£2.80, £1 40). The former is a timely review of a fascinating and fast developing area of plant physiology, and once again it includes simple laboratory experiments. The second book is really an expansion of the authors' paper in *Nature* (**227**, 145; 1970) It makes interesting reading, but is rather specialised for this series and suffers from the disadvantage that the taxonomy of lichens is sufficiently difficult to put the application of this technique for pollution detection out of the reach of the average undergraduate. Species descriptions are included but a simple, illustrated key to the more important indicator species would have made this a much more useful book.

The *Tertiary Level Biology* series (hardback and paperback), published by Blackie (Glasgow and London), also aims at the undergraduate, but has a more advanced approach, thus making it of value to postgraduates too. *Water and Plants* by H. Meidner and D. W. Sheriff (£5.50; £2.90) is the latest issue in this series, and begins by describing the properties of water and the concept of water potential. In a logical order it then considers water vapour and transpiration, water transport in the plant, and the plant–soil relationship. This is certainly not an introductory book and the undergraduate would need to be weaned on a lower level text, such as the Edward Arnold study by J. Sutcliffe. It does, however, provide a full, thermodynamic and mathematical basis for understanding the current state of the study of plant–water relations.

Hutchinson (London) have also begun a series of introductory studies in biology. The third and latest title in this series is *Microbial Plant Pathology* by P. J. Whitney (£4.95; £2.95). This is a well-produced and readable book which assumes no previous knowledge of the subject. It begins with an account of disease transmission which concentrates on crop diseases, and which underlines the economic importance of plant pathology. It then considers infection, defence mechanisms and pathogen-induced reaction in the host species. It is a clear and concise introduction to the subject and is good value for its price.

One of the latest issues in the *Oxford Biology Readers* series (Oxford University London) also deals with plant pathology and is entitled *The Control of Plant Disease* (30 pence), by B. E. J. Wheeler (who, incidentally, is also author of *Diseases in Crops* in the Edward Arnold series). The idea behind the *Oxford Biology Readers* is brevity and, consequently, low price. These aims are undeniably achieved, but at the expense of depth. Usually they are about 15–30 pages long, and this kind of treatment demands very careful selection of material Some subjects are more suitable for a brief survey than others. Plant pathology cannot be covered adequately in 15 pages although Wheeler does achieve an interesting introduction to the problem of disease control. The topic chosen for an issue in this series must, therefore, be relatively narrow in scope. For example, in the issue entitled *Stomata* (60 pence), Heath admirably attains a detailed analysis of the physiology and mode of action of these organs.

Oxford Biology Readers are performing a very different function from the other monographs reviewed here in that they have such limited coverage within each issue. Because of this they do not generally form a basis for a specific undergraduate course but provide supplementary information on certain topics within such a course This must limit their sales potential among undergraduates despite the high quailty of some of these booklets

Having examined several of the biological series currently being served up for undergraduate consumption, one cannot help being impressed by the Edward Arnold's *Studies in Biology* These appear to have struck the best length of treatment and selection of topics to meet the widest student demand. The publishers should be congratulated on anticipating so accurately the growing demand for this type of publication. **Peter D. Moore**

Peter Moore is Lecturer in the Department of Plant Sciences, King's College, University of London, UK.

BIOLOGY has become such a diverse subject, and one in which there are so many rapidly-developing areas, that the single, comprehensive textbook covering the whole field has become largely obsolete. A new development has been the production of series of smaller, cheaper books, to which new, up-to-date titles on specific topics can be added as they become appropriate. Such series have the advantage that lecturers and teachers can selectively stock their libraries with material that is directly relevant to their particular courses without having to pay for additional material they do not require.

The *Oxford Biology Readers* series (Oxford University: London) are essentially a series of essays on a variety of biological topics—some very specific, others more general—written by authors who are pre-eminent in their particular fields. Each provides a concise and authoritative introduction to its subject They are well produced with clear photographs and excellent diagrams and they include fairly comprehensive suggestions for further reading They are excellent value and provide an invaluable source of basic information for students at advanced school and undergraduate levels.

In *Primate Locomotion* (45 pence) Professor J. R. Napier describes the variety of locomotor patterns found in primates and discusses how these have evolved in relation to the habitats in which primates live and the various types of food that they eat. He also discusses the rather scanty evidence relating to the locomotion of fossil primates and the special skeletal adaptations for bipedalism shown by man.

Insect Flight (45 pence) by Professor J. W. S. Pringle deals with many aspects of a complex subject in a remarkably clear and concise way. He discusses the different mechanisms found in insects, the aerodynamics of flight, the physiology of insect flight muscles and the control and coordination of flying This *Reader*, which is illustrated by exceptionally clear diagrams, can only provide a rather cursory examination of such topics, but perhaps its principal value is that it encourages the reader to pursue the subject further.

The Echinoderms are a group of animals that differ from other Phyla in so many ways that there is a tendency to regard them as somehow being off the main stream of evolution Professor D. Nichols, in *The Uniqueness of Echinoderms* (45 pence) sets out to convince the reader not only that they have a fascination in their own right but that (because of their abundance in the marine environment and the fact that, through the echinoderm larva, they may be the ancestors of the chordates) they are entitled to more attention from zoologists. His enthusiasm for these animals is evident in this lively and interesting little book.

In *Evolution Studied by Observation and Experiment* (45 pence), Professor E. B. Ford discusses the contribution to our understanding of evolution made by the study of ecological genetics, a field in which he has been a major influence. He shows how the study of various characters under natural conditions has revealed that selection pressures favouring advantageous characters are much more powerful than Darwin and other early evolutionary theorists had believed was possible and that natural selection can bring about adaptive changes very much more quickly than was previously supposed His evidence is drawn from studies by himself and others, including those on colour patterns in butterflies, shell colouration in snails and the human blood groups

During the development of the science of animal behaviour certain theoretical concepts have been developed and have subsequently been the focus of considerable debate and disagreement. Robert and Joan Hinde discuss two such concepts in *Instinct and Intelligence* (45 pence) Using a wealth of examples they show how instinct has become a somewhat disreputable concept, whereas intelligence now has a precise scientific meaning, more restricted than its everyday usage. They argue strongly against using either concept as an explanation for behavioural phenomena and suggest that they are important as ideas that point to problems and to areas of investigation, which should ultimately make them redundant

The story of the evolution of the birds from the reptiles through the fossil *Archeopteryx*, has been told many times. In *The Evolution of Flying and Flightless Birds* (45 pence), Sir Gavin de Beer provides a concise and well-illustrated discussion of this topic, together with the evolution of the ratites, a group which, because of their flightlessness and geographical distribution, have exercised the minds of evolutionary theorists for many years. Since de Beer's death in 1972 there have been some interesting developments in this field, notably Ostrom's re-analysis of *Archeopteryx*'s wing and Cracraft's theory that the ratites are descended from a single flightless ancestor which was dispersed by continental drift.

All these *Readers* can be highly recommended. They provide, in a concise and clear way, an invaluable source of information which can provide a sound basis for further study.

The philosophy behind Arnold's *Studies in Biology* series (London) is an essentially sound one. The series provides a medium by which biologists can be kept up to date with developments in specific areas of biology. They are reasonably priced and are an ideal way by which individuals, schools, colleges and universities can supplement their libraries in particular fields.

Small rodents and insectivores have provided much of the data that form the basis of population and community ecology. In *The Ecology of Small Mammals* (£1.90; 95 pence) Dr M. S. Delany strikes a nice balance between discussing them as animals of interest in their own right because of their abundance, economic importance and role in the terrestrial ecosystem, and showing how they have contributed to general ecological theory. He covers a great deal of material, deliberately widening his subject matter to include species from as far afield as East Africa, America and the Far East. He does not attempt a comprehensive review of this material but aims to highlight the areas in which new developments are taking place.

The book begins with a discussion of some of the basic methods of trapping small mammals and of estimating their ages, home ranges and population densities. It then considers the life histories and demographic patterns found among these animals in different habitat types around the world. This is followed by a chapter on populations and the way they are affected by seasonal changes, food supply and predation. The final chapter deals with relationships between small mammal species and the way communities of species are related to different habitats.

Dr Delany's book is clearly and concisely written, well illustrated and fully referenced Perhaps its greatest virtue is that it leaves the reader with the motivation to read further on the subject.

The student of zoology is generally brought up with the notion that animals are anatomically symmetrical, and great stress is laid on such characters as radial and bilateral symmetry as fundamental features of different animal types. In *Animal Asymmetry* (£2.60, £1.30) Dr A. C. Neville points out that asymmetrical organisation is commonly found right across the Animal Kingdom. For each example he shows how asymmetry is adaptive in the life of the animal. Some insects have left and right wings of slightly different shapes so that they can be folded one over the other. Owls have differently shaped left and right ear apertures that enable them to locate sounds with great accuracy. Such asymmetries raise interesting questions in developmental biology and Dr Neville discusses briefly how they may arise during embryonic development in molluscs, insects and other animals. He also points out that asymmetry is a property of organic molecules and of the carbon atom itself.

Dr R. F. Chapman's book, *A Biology of Locusts* (£2.80; £1.40), should prove invaluable to any school or university laboratory that keeps a colony of locusts. It deals with the basic biology of these insects, their life history, feeding behaviour, flight and migration. The book also discusses the ecology of locusts in the wild, particularly from the point of view of their impact as serious agricultural pests. Finally, he discusses the various techniques that have been used to control locusts and also those that are now being developed. This is a very useful book because it contains, in a very readable and clearly illustrated form, virtually all that one could want to know about animals that are used very widely by students at all levels.

The aim of the series, *Topics in Biological Sciences*, published by Hutchinson (London), is to emphasise the social and economic importance of a number of biological topics. *The Biology of Insects* (£4.95; £2.95), by C P. Friedlander, begins with an account of the structure, physiology and natural history of insects, along the lines that one finds in many biological textbooks. This is followed by a chapter on their behaviour and ecology and, finally, a chapter on the economic importance of insects and the methods used to control them. So wide is the scope of this book that its coverage of any one topic is of necessity rather superficial, and it is difficult to see that it represents an advance on existing entomology texts. *The Biology of Locusts*, however, in the *Studies in Biology* series, which considers only one species of insect, brings out much more successfully the way that an understanding of an insect pest's biology can contribute to its effective control.

Also in this series, *Freshwater Biology* (£4.95; £2.95), by L. G. Willoughby, similarly attempts to cover a very wide field. It deals successively, as most books on freshwater biology do, with the physical and chemical properties of water, with freshwater plants including algae, and with a number of aquatic invertebrates and fishes. There is a brief chapter on features peculiar to running water habitats, and a longer one on decomposition cycles and nutrient recirculation. The chapters on social and economic aspects, such as water supplies, sewage treatment and pollution are very brief and serve only to outline these important topics. This book suffers, like its companion volume, from trying to cover too much material in too small a book. The attempt to combine basic biology with social aspects is not very successful; the latter seem to have been added almost as an afterthought. These books are not cheap and certainly not as good value for money as the *Studies in Biology* series.

These three series provide an interesting contrast. The authors of the *Oxford Biology Readers* are for the most part senior, distinguished biologists, and they have written with the authority one would expect on what are generally traditional biological topics. The *Studies in Biology* series are mostly written by a younger generation of authors, and their titles and style reflect a rather more progressive approach to biology. Both series can be highly recommended; they are cheap, well illustrated and well written. There is perhaps a risk that the *Oxford Biology Readers* will be used merely as 'essay cribs' by students; the *Studies* are more likely to stimulate an enquiring approach in their readers. The Hutchinson series has not been nearly as successful as the other two. Although well illustrated, they attempt to cover too wide a field in each volume, and their price brings them into competition with more thorough and complete textbooks, with which they do not compare very well.

T. R. Halliday

T. R. Halliday is Lecturer in Zoology at the University of Oxford, UK.

THE emergence of membranes as a major growth area in biological science has naturally provoked a proliferation of student texts in this area. These supplement the accounts to be found in general textbooks of biochemistry and cell biology and would therefore be expected to provide the integration and advanced information that these texts omit, but without too much repetition of readily available foundation material.

An attractive book, appropriate for students, is Weissman and Claiborne's *Cell Membranes: Biochemistry, Cell Biology and Pathology* (HP Publishing: New York, 1975, £12.00), but the price means that students are likely to read it only in a library It is well written by eminent authors, but the multiauthor format sometimes leads to repetition (for example, Rasmussen and Goldberg, Pappas and Loewenstein) and to an imbalance between the relative importance of a topic and the space allowed to it.

A student wanting his own membrane text then has a choice. Either he can get one of several small books that aim at a complete basic coverage of membranes, such as Saier and Stiles, Harrison and Lunt or a competitor (Quinn, *Molecular Biology of Cell Membranes*, Macmillan, 1976, £8.45; £3.85; Finean *et al.*, *Membranes and their Cellular Functions*, Blackwell, 1974, £2.80; Parsons (ed.), *Biological Membranes*, Oxford University, 1975, £5.00) or he can select his information piecemeal from series publications such as Oxford University Press' *Biology Readers* (London) or Chapman and Hall's *Outline Studies in Biology* (London).

Of the single texts, M. H. Saier and C. O. Stiles' *Molecular Dynamics in Biological Membranes* in the *Heidelberg Science Library* (Springer: Berlin and New York, DM 13.80; $5.70) is most biologically oriented (despite its misleading title). The authors have a firm, maybe correct, unitary belief that membranes are all similar and that function invariably depends on structural fluidity; this sometimes leads to unsupported statements such as "(Intercellular) junction formation is undoubtedly dependent on membrane fluidity". Sometimes, they lose sight, however, of their unitary philosophy, as when sensory chemoreception (for example, taste) and hormonal chemoreception (for example, insulin receptor) appear in different chapters. These problems, and the limited and personal choice of topics discussed, makes the book unsatisfactory as a central student text. It does, however, include useful accounts of a number of membrane-mediated processes not normally treated in small texts (for example, bacterial chemotaxis, membrane fusion, and so on), provided the reader does not expect attempts at molecular explanations.

By contrast, R. Harrison and G. G. Lunt, in *Biological Membranes Their Structure and Function* in the *Tertiary Level Biology* series (Blackie Glasgow and London, £7.80 hardback; £3.90 paperback), have aimed at a systematic and balanced text with membrane chemistry as its dominant theme The result is good but patchy They are at their best when discussing "Membrane carbohydrate and cell surface specificity" and in a valuable and concise section on physical methods used in membrane studies More than half of the remaining space is allotted to membrane, morphology, composition, isolation and structure, with a lot of space occupied by electron micrographs of doubtful educational value and by basic lipid chemistry (including three illustrations of the same glycerophospholipid structures) This overindulgence restricts the space available to membrane functions (transport, secretion, turnover, enzymes, receptors, and so on) even though they have equal billing in the title.

Membranes feature in the *Outline Studies in Biology* series (£1.30 each) in the recent books by A. M. Malkinson and by M. F. Greaves, in M Davies' *Functions of Biological Membranes* (better titled *Membrane Transport*) and in a promised *Membrane Assembly*. Malkinson's *Hormone Action* presents twin discussions on hormone actions mediated through cell surface receptors and through intracellular receptors. This contrast is useful, and the material presented is up-to-date Only about one third of the whole, however, relates to membranes Greave's *Cellular Recognition* is an excellent text that draws together diverse phenomena (hormones, neurotransmitters, the immune system, tissue differentiation, sex in yeasts, and so on) and discusses them in terms of the reception and interpretation of environmental information at the cell surface. It is logical and well organised, with substantial sections on membrane structure, receptors, and mechanisms of stimulus–response coupling. A major virtue of series publications is that it can allow an articulate specialist to pass on his fascination with such a problem. But the series format also has drawbacks the high cost of collecting the books needed to achieve a final patchy coverage, duplication of fundamental information on membrane structure, and sometimes poor editing and presentation.

Two *Oxford Biology Readers* fall into the membrane category, and are straightforward biochemical introductions to their topics. J A. Lucy in *The Plasma Membrane* (45 pence), has packed a lot of basic information on membrane structure, turnover, fusion and transport (illustrated diagrammatically as an unlikely rotating macromolecule) into his 16 pages. Hormones are left to P. J. Randle and R. M Denton's *Hormones and Cell Metabolism* (45 pence), a balanced and appropriate short account of metabolic control. This, however, has little on membranes other than control of adenylate cyclase, and is marred by inconsistency of units (insulin) and nomenclature (phosphorylase), repetition of diagrams and some almost illegible yellow-on-white printing. Other useful membrane-related titles in this series are *Lysosomes* (A. C. Allison). *The Golgi Apparatus* (G. M. W. Cook), *Mitochondria* (J. B Chappell and S. C Rees) and *Differentiation in Higher Plants* (D. H. Northcote).

If I could select only one item from this collection it would undoubtedly be Greave's *Cellular Recognition*: it wins both on scientific quality and value for money, even though it explores only one area of membrane function.

Bob Michell

Bob Michell is Lecturer in Biochemistry at the University of Birmingham, UK.

"OF making many books there is no end . . . Fear God, for this is the whole duty of man" Statements like this frequently explode from scientists drowned in a suffocating morass of reading—even though their theological intent may be different to the original Old Testament context. Nevertheless it could be an apposite comment about the eight books under review: all come from long and continuing series, four from Chapman and Hall's *Outline Studies in Biology* which includes 22 titles published since 1973 (London, distributed in USA by Halsted/Wiley: New York; three from Arnold's *Studies in Biology*—71 published since 1966 (London); and No. 72 in Oxford University Press'. *Biology Readers* series, which began publication in in 1971 (London)). All the series state that they are trying to fill gaps left by standard textbooks, either at the interface between traditional disciplines or in rapidly developing topics where textbooks are quickly out-of-date.

The Oxford series is the slightest in format, designed so that each one "will fit conveniently in a file among the students own notes" The series is specifically aimed at sixth-formers (school children at advanced level), students in Colleges of Education and Polytechnics, and first-year undergraduates. Each volume (really pamphlet—they have about 14 pages) covers a specific limited subject in reasonable depth and with good illustrations. J. L. Jinks's *Cytoplasmic Inheritance* (45 pence) is only one of 19 in the series devoted to genetics and evolution; like its companion volumes it has no bibliography but a list of "further reading", which includes five books and five reviews or key papers.

The other two series are directed at the second- to third-year university level, although they are in general free from jargon and thus potentially valuable to sixth-formers and their ilk. Chapman and Hall's *Outline Studies* (paperback editions only) cover subjects which may be expected to form a normal university course of 5–10 lectures. Arnold's *Studies* (hardback and paperback editions), on the other hand, tend to deal with topics that do not fall neatly into usual teaching slots, and for that reason seem to be more stimulating. For example, Bernard John's *Population Cytogenetics* (£3; £1.50) is concerned with both animal and plant chromosomes; with population phenomena as well as straight cell biology, and with the quantitative effects of chromosome substitution. This enables the author to point out that knowledge is lacking about population cytodynamics and the effects of chromosome rearrangements on the genetical structure of populations—fairly complicated concepts which emerge naturally because of the interdisciplinary treatment of the subject. In contrast, D M. Moore's *Plant Cytogenetics* (£1.30) and L M Cook's *Population Genetics* (£1 30) in the *Outline Studies* series, although both are excellent in their own ways (Cook in particular weaves mathematical formulation with natural history in a refreshingly non-intimidating manner), are almost inevitably more pedestrian. They will be useful for supplementing courses where no teacher is available for the topics considered (or alternatively, for providing unversed teachers with prepared teaching material).

One disadvantage of the lecture-course approach in a book is that it exposes gaps in treatment which would (or should) not appear in a comprehensive textbook and which would probably be filled by other teaching in a complete school or university course. For example, R A. Woods in *Biochemical Genetics* (*Outline Studies*, £1.30) gives a useful summary of gene action and its control in microorganisms, but does little more than mention higher organisms. He justifies this limitation by claiming that "the information they [microorganisms] have yielded is 'cleaner' and more suited to an outline text" True, but this means that the title of the book is misleading. Again in the same series, A. McDermott gives a full introduction to human chromosomes and their variation in the *Cytogenetics of Man and Other Animals* (£1.30) (a topic which is only touched on in general biology or genetics texts), but *other animals* are only referred to in passing, largely in relation to human studies.

The *Studies in Biology* series is sponsored by the Institute of Biology, and this academic input may explain their imaginative choice of topics. One criticism that has been levelled at the series in the past is the relative lack of references in many of the volumes. In fact the three volumes from the series under review seem to contain enough key references for practical purposes. The *Outline Studies* series is variable· two of the present books have fairly extensive bibliographies, the other two merely a selection of "further reading".

Two other recent and relevant titles in the *Studies in Biology* series are *Genetics and Adaptation* characterised by E B. Ford's usual lucid and idiosyncratic style; and *Population Dynamics* by M. E. Solomon, a new edition of a useful book first published in 1969 and now fairly extensively revised

One great advantage of limited topic books is that leaders of research in particular fields can write on their own topic: four of the eight under review are written by authors who have previously published substantial works on the same subject (Cook, Ford, Jinks and John) The *Studies* and *Outline Studies* series both work out at 2 pence per page in paperback; this is quite good value for money nowadays. It is difficult, however, not to hark back to the Penguin *New Biology* series which lasted from 1946 to 1960 and filled the gaps in textbooks so well at the time. But perhaps biology as well as publishing has changed . . . **R. J. Berry**

R. J Berry is Professor of Genetics in the University of London, UK.

FEW books pack so many lessons for the plant physiological world as the slim volume on *Translocation in Plants* by Michael Richardson, No. 10 in Arnold's *Studies in Biology* series (£1.90; 95 pence). The book—now in its second edition and proclaimed an Open University Set Book —has already served many generations since first published in 1968. Why its popularity? It takes the form of six chapters with well defined subsections, almost suggesting it began life as a revamped set of lecture notes. Perhaps this explains its sales success, but also its failings?

Probably the most glaring error is the use of a water hammer (pp18–19) to measure the cohesive properties of xylem sap. Nowadays students see more mass spectrometers than Berthelot tubes or water hammers, and few would have sufficient knowledge to question explanations given Dixon made the water hammer (1914) to illustrate cohesive attraction between water and glass in the presence of gas near vacuum. The experiment determining the limiting cohesive tension of water was carried out by Berthelot (1850) in a tube filled completely with water: both systems were described clearly by Dixon.

Phloem research has advanced rapidly in the past decade. Broadly the position is one in which the model proposed by Hartig and expounded more precisely by Münch (1930) has become established and received widespread acceptance. For centuries it was obvious that channels for dry matter translocation existed in bark of plant stems. After the discovery of sieve tubes the main question outstanding was why phloem sap should not flow through these pipe-like cells, carrying dry matter in solution to swell storage organs, ranging from the humble spud to the massive fruits of palms.

The main reason sieve tubes might not function like pipes, translocating the sugary sap, arose from the fact that at frequent intervals sieve tubes are occluded by sieve plates, the holes in which seemed to be plugged in both light and electron microscope studies. This observation gave rise to some alternative hypotheses and "the great phloem controversy". Most alternatives are faithfully reproduced and even extended in the new edition of the book. Yet considerable strides have been made in phloem physiology from studies of plants which, on wounding, exude phloem sap, as might be expected by Münch's hypothesis. Virtually none of this work has found its way into the new edition. There is some justification to withold some of the detailed electron microscopy which has contributed to the widely held view that sieve plates serve a protective function, sealing rapidly when the system is injured. But the omission of this aspect so completely cannot be excused, because it is so central to the theme of the book. Nor is it legitimate to call aphid stylet sap "uncontaminated" (p36) on account of saliva injection effects (see, for example, *Biology of Aphids* by A. F. G. Dixon, *Studies in Biology* No. 44; 75 pence).

Another *experimenta crucis* which has contributed to the phloem controversy is the alleged demonstration of bidirectional transport in phloem. Certainly no sieve tube could, if it functioned as a pipe, conduct simultaneously in opposite directions at rates exceeding those of diffusion. But the experiment chosen to illustrate this, by Palmquist (1939), is dangerously misleading, as is obvious to anyone who has carried out even limited research on the system. The problem is that xylem pipes, containing sap under tension, lie in close proximity to the highly pressurised sieve tubes being investigated. Abraided leaves can rapidly suck solutions into xylem tubes producing an illusion of bidirectional transport. Much better research (for example, Turgeon and Webb, 1973) would have been desirable alternative material. Similarly much of the earlier work could have been omitted without loss. Sadly the five new pages and seven new paragraphs are largely (especially with hindsight) irrelevant.

The success of this book is a disturbing reflection on both scientific and publishing fraternities. If a better alternative of comparable cost existed, I hope students would have been guided to choose it in preference: such a volume is clearly lacking. If errors have escaped criticism so long, does this imply the capacity to publish extends beyond a proper degree of rigorous criticism? It is indeed regrettable that this book mars the high standards of the series as a whole. **John A. Milburn**

John A. Milburn is Senior Lecturer in Botany at the University of Glasgow, UK.

In the past two years, three publishers have made additions, in the field of muscle biology, to their (continuing) series of books designed for late school or undergraduate consumption. Oxford University Press (London), in their *Biology Readers* series, have produced a 16-page pamphlet entitled *The Contractile Behaviour of Mammalian Muscle* (30 pence) by A J. Buller; Arnold (London) have persuaded D. R. Wilkie to write a second edition (hard and paperback) of his book on *Muscle* (£2.50; £1.25) in their *Studies in Biology* series; and Blackie (Glasgow and London) have produced a specialised text on *Visceral Muscle· Its Structure and Function*, (£5.10) by H. Huddart and S. Hunt.

Muscles, according to Professor Buller and Wilkie and Doctors Huddart and Hunt, respectively, are more important in getting animals about than brains, are the means by which we act on our environment and move objects as well as ourselves; are a tissue and therefore by definition composed of cells These paraphrased quotations from the first lines of the three books are characteristic and exemplify their approaches.

The books vary enormously in length and in their scope and coverage. Professor Buller concludes all he has to say in 16 succinct pages, of which 5 are taken up by illustrations Wilkie covers his subject in 67 more sparsely illustrated pages, whereas Huddart and Hunt pack their comprehensive but more specialised subject matter into 165 The shortest work concentrates almost exclusively on isometric and isotonic contractions of fast and slow twitch skeletal muscles, having briefly introduced the subject by way of the ultrastructure and the nervous architecture of muscle. Professor Wilkie, as becomes a pupil of A V. Hill, does not neglect the thermodynamics of muscle energetics, but also introduces the subject by means of the ultrastructure and chemical composition of muscles In his book, he gives an overview, taking his examples from all sorts of muscle and from many species He describes the common experimental methods used in examining muscles, pointing to their shortcomings. He explains the results obtained in terms of the known structure. He leads the reader rather gently through a clarification of the electrical phenomena in quiescent and stimulated muscle and illuminates the chemical changes that result in contraction Finally, he brings us back to everyday experiences by describing how muscles maintain tone and enable us to take exercise.

The largest, although still slim volume, has a wider target for a narrower topic. It claims to be of interest to students of physiology, medicine, biology and pharmacology and deals specifically with *Visceral Muscle* It is the most conventionally organised of the three; once again, the contents run from microscopic structure through innervation to mechanical activity, but conclude with the protein structure and the molecular basis of contraction Although some of the chapters are of course specifically oriented to visceral muscle, it is surprising how often comparisons are made with experimental work in skeletal and cardiac muscle.

Clearly, here is a triad of books that can be used quite differently, yet they are linked by a unity, since much of the material is common to the three. Wilkie's book stands out above others in the way that it simplifies complex ideas and yet has more than enough meat for any hungry student. Anyone remotely interested in muscle—and who among biologists is not—can—and one might almost say should—read it. The result will be not only an increase in knowledge and understanding, but an experience of an outstanding example of written communication. In addition, the author is a realist who has the interest of students at heart; he does not give the usual unmanageable list for further reading, but confines himself to a few seminal works.

Buller's contribution is more a pamphlet than a book; it probably contains all that a student need retain about the fundamentals of muscular contraction The question arises: is he more likely to retain nearly all of this or only a quarter of the slightly longer text? The answer must depend on the assessment of the teacher and the character of the student. It would be reasonable for any biologist or medical student to read a mere 11 pages, but how many have the time or the inclination to read ten times that many on a single subject? The beauty of this pamphlet is that it is short, lucid and expert, yet it does not have unrealistic expectations of the reader.

What then of the last book? It is not for every student; its primary use might be for reference, for each chapter is almost complete in itself, containing at least two key references. In addition, there are some 150 further references, and above all it is the only one of the three with an index.

It seems that these three complementary works offer three solutions to the problem of the modern science student—an elegantly produced evening's reading for tomorrow's seminar, a readable text from which something will be remembered, or the small reference for a narrow subject to be dipped into as required. You pays your money (0 30; £1.25 or £5.10) and you takes your choice.

Rainer Goldsmith

Rainer Goldsmith is Professor of Physiology at Chelsea College, University of London, UK.

Most immunologists are preoccupied with problems pertaining to mice or men, but many are now showing an increasing interest in the immunological responses of other species in order to discover evolutionary trends in recognition of foreigness, structure of antibody molecules and mechanisms of protective immunity.

In *Comparative Immunobiology* (£6 60, £3.30), in Blackie's *Tertiary Level Biology* series, Margaret Manning and Rodney Turner are the first authors to write a textbook of suitable size and clarity for students of immunobiology Indeed, this book can be recommended to anyone seeking an introduction to comparative immunology Other books have been and are being written on this subject but great credit must go to these authors for providing a book which will obviously remain a basic textbook on the subject for many years to come

Those immunologists already involved with the vagaries and complexities of immunological responses in different species will admire the layout of the book. First, there is a 28-page introduction on the basic tenets of immunology, largely derived from work on mammals and birds. There follows an ambitious description of immunological responses as we climb the 'evolutionary tree' from sponges to fishes and terrestial animals Each chapter is introduced by an accurate phylogenetic tree Phyla which have been sufficiently studied by immunologists are lucidly described in clearly defined sections headed 'phagocytosis', 'transplantation reactions', 'humoral reaction and factors' and 'lymphoid tissues'

One of the most intriguing aspects of invertebrate immunology is how animals with no lymphocytes can recognise foreign species. This is treated adequately here, but new theories on recognition now appear monthly

The bursa of Fabricius is wisely described as being unique to birds (p149), and this should be a warning to those immunologists still hunting for a 'bursal equivalent' in mammals

This is a concise book, small in appearance but large in its breadth of treatment and factual content. All immunologists should find time to read it **J. B. Solomon**

J B. Solomon is Senior Lecturer in the Iammunology Unit of the Department of Bacteriology, University of Aberdeen, UK.

Oxford Books for Students

New and forthcoming

Foundations of Mathematics

Ian Stewart and David Tall

This is a book for readers in transition from 'school mathematics' to the fully fledged type of thinking used by professional mathematicians. It should prove useful to first-year students in universities, polytechnics, and colleges, and to sixth-formers contemplating further study £6 paper covers £2.95

Nonlinear Ordinary Differential Equations

D. W. Jordan and Peter Smith

This textbook in the qualitative theory of nonlinear differential equations is for students in mathematics or in mathematics-orientated combinations and is directed towards practical applications. It treats recent developments and subjects such as singular perturbations and the phenomena associated with forced nonlinear equations that have not been readily accessible before at this level. £11 paper covers £5 50 *Oxford Applied Mathematics and Computing Science Series*

Mathematical Cosmology

An Introduction

Peter T. Landsberg and David A. Evans

Cosmology is a subject of much scientific and philosophical interest, but accounts are usually either non-mathematical or fully relativistic. This book gives readers a quantitative understanding of some important aspects of general relativistic cosmology, starting only with school mathematics and Newtonian ideas in physics £8.50

Elementary Thermodynamics for Geologists

B. J. Wood and D. G. Fraser

This introduction to chemical thermodynamics, intended for geology students with little previous knowledge of physical chemistry, illustrates the use and usefulness of the thermodynamic approach to petrology It avoids an abstract development of the subject and, though rigorous, assumes only a limited background of mathematics, including elementary calculus. £6 paper covers £2.95

Human Biology

An Introduction to Human Evolution, Variation, Growth and Ecology

G. A. Harrison, J. S. Weiner
J. M. Tanner and N. A. Barnicot

This textbook has now been revised to include the many recent advances in the fields it covers, especially those in our knowledge of primate and human evolution, genetic variation at the molecular level, and the nature of growth and adaptation processes. There is also a completely new chapter on primate behaviour and the origins of human society. Second edition illustrated £10 paper covers £5.50

Oceanography

Contemporary Readings in Ocean Sciences

Edited by R. Gordon Pirie

First published in 1973, this collection is intended as a supplementary reader for first- and second-year undergraduates in ocean sciences In this second edition the articles are generally briefer, more elementary, and more popular; thirty-one of the forty-six selections are new. Second edition paper covers £6.75

Kinetics of Chemical and Enzyme Catalyzed Reactions

Dennis Piszkiewicz

This volume is intended to serve several functions. It is meant as a means of teaching kinetics to advanced undergraduate and graduate students. It presupposes a background in organic chemistry and some knowledge of calculus, while a familiarity with biochemistry and chemistry would be useful, though not essential. It is also intended as a primer for reading papers in the literature dealing with kinetics. Paper covers £4.75

Industrial Geology

Edited by J. L. Knill

This series of essays provides an introductory survey of applied geology for the more advanced undergraduate or the postgraduate student, those who are teaching geology, and planners concerned with geological resources. The contributors, writing from extensive experience, have provided examples of the application of geology in practice and the roles played by geologists in industry. £10

Circle No. 10 on Reader Enquiry Form.

WILEY
INTERSCIENCE

ABNORMAL AGEING: The Psychology of Senile and Presenile Dementia

by **E. Miller**, *University of Southampton.*

Ageing is rightly a topic of increasing concern and research interest. The growing proportion of the elderly in the population raises many important issues for society, and presents some problems. Dementia is one of the commonest and yet most difficult disorders found in older people, and the basic aim of this book is to present the psychological aspects of dementia.
The author reviews what is known about the psychological changes produced by dementia and discusses the practical contributions that psychology can make in dealing with the demented individual.

0471 99439 1 176 pages February 1977 £5.75/$11.00

PHARMACOLOGY: Drugs Affecting Behavior

by **C. Kornetsky**, *Boston University School of Medicine.*

Describes the physiological and psychological effects of drugs used in treating the mentally ill, the epileptic, and the hyperkinetic child, and presents various theories concerning the mechanisms involved in the therapeutic action of drugs and the pharmacology of abused drugs.

0471 50410 6 288 pages September 1976 £14 00/$24.50

IMMUNOCHEMISTRY OF ENZYMES AND THEIR ANTIBODIES

edited by **M. R. J. Salton**, *New York University Medical Center.*

Leading medical scientists pool their collective experience to formulate basic principles for the interaction of enzymes and antibodies and explain how these interactions can be used to solve complex molecular and biological problems Features selected model systems illustrating the use of enzyme/antibody interactions to establish molecular structure and architecture of enzymes (Developments in Medical Microbiology and Infectious Diseases)

0471 74995 8 240 pages February 1977 £14.25/$24 15

IMMUNOBIOLOGY FOR THE CLINICIAN

by **H. R. K. Barber.**

A concise, overall view of the basic concepts and recent developments in immunology. Topics include: Structure of a Normal Cell and Cancer Cell Kinetics, Immunity, Antigens, and Viruses in Relation to Cancer; Immunodeficiency Diseases, Immunohaematology; Immunosuppression, Immunology of Cancer; Immunotherapy and Immunopotentiation.

04710 4785 6 320 pages February 1977 £14.65/$24.75

TROPICAL CLIMATOLOGY: An Introduction to the Climates of the Low Latitudes

by **S. Nieuwolt**, *Department of Geography, Kenyatta University College, Nairobi.*

This textbook is intended for students of geography, biology and agriculture whose studies include a course on the climate of tropical regions and the effects of the weather upon man's activities in these regions.
The book explains the origin of the tropical climates in a non-mathematical way and all quantitative data are illustrated by maps and diagrams

0471 99406 5 218 pages February 1977 £6.95/$15 00

GEOLOGY OF CALIFORNIA

by **R. M. Norris** and **R. W. Webb**, *both of University of California, Santa Barbara*

The first systematic, comprehensive text covering major fundamental elements of the geology of California The book incorporates the most recent research on the basic geology of the earth's crust as reflected in the visible geology of the provinces of the state of California

0471 61566 8 392 pages February 1977 £9 35/$16.00

CELLULOSE AS A CHEMICAL AND ENERGY RESOURCE

edited by **C. R. Wilke**, *University of California*

This contains papers by scientists and engineers actively involved in research related to cellulose The papers were presented at the Cellulose Conference Proceedings, held under the auspices of the National Science Foundation, at the University of California, Berkeley, June 1974

0471 01549 0 370 pages March 1976 £14 50/$25 20

MICROPROCESSORS AND MICROCOMPUTERS

by **B. Soucek**, *State University of New York, Stony Brook and Institute Ruder Boskovic, Zagreb*

Describes the general programming and interfacing techniques common to all microprocessors, concentrating on detailed description of representative microprocessor families Numerous illustrations, examples and a bibliography are provided along with exercise problems

0471 81391 5 624 pages April 1976 £17 00/$29 75

Embarking on biochemistry

WHEN, until recently, I lectured to large groups of science or medical students embarking on a course of biochemistry, I took along to the first lecture about 15 different texts. I tried to explain the merits of the various books in terms of the widely varying attitudes of the students After the lecture many students would stand perplexed and some would even express their feelings to plead that they be told what to buy I understood their viewpoint but I think, as teachers, we must resist the students' plea The truth is, of course, that biochemistry is blessed with a wealth of excellent texts and the best-buy for any particular student is seldom an easy decision The problem is made more difficult in the knowledge that unless a student buys a textbook by half-way through the first term he is unlikely to do so at all. In other words he has often to make his choice before he has much idea as to his interest in the subject.

The two texts under review are both excellent in their way. A L Lehninger's *Biochemistry The Molecular Basis of Cell Structure and Function* (Worth. New York, second edition, $17.50) is now clearly a classic and is extremely popular with students both of science and medicine. It is also comparatively cheap in terms of length and the excellence of the printing *The Biochemistry of the Tissues* (Wiley London and New York, second edition, hardback £14 50, $30, paperback £6 25, $13.50) by P Banks, W. Bartley and L M. Birt is a more modest effort, based on their lectures to medical students at Sheffield University

A continual problem in the teaching of biochemistry is to keep the picture of the subject as a whole before the student Too often the older courses appeared fragmentary and the student lost the unity of the subject while they delved into the minutae of the various aspects Lehninger keeps the story going by starting with a set of organising principles and continually referring back to them as he deals with various subjects The story holds together very well and this is undoubtedly a main attraction for the students The Sheffield authors had a particular group of students in mind and have tried to hold attention through a consideration of the biochemistry of the various tissues The student has to be prepared for this approach, however, so that the earlier chapters are a somewhat skimped traditional text

In some ways *Biochemistry* by L Stryer (Freeman San Francisco), has much to offer medical students In this beautifully produced book reference is continually made to the relevance of biochemistry to medicine and physiology Thus there is an excellent chapter on sickle-cell anaemia Indeed there have been attempts to organise a course of biochemistry on a selection of such diseases One thinks of *Biochemistry A Case-Oriented Approach* (Mosby Missouri) by Montgomery *et al*, but again there are snags, for the student must have a proper groundwork before he is ready for this kind of treatment

Another unifying approach that is now often used in first year courses is to develop the biochemistry from an elementary study of cell biology. This is probably better than concentrating on the tissues. So far, however, I have not seen a textbook based on this kind of course

In summary, both books reviewed have their strong points and certainly the latter part of the Sheffield book would prove a useful adjunct to the cheaper and much more comprehensive Lehninger text **P. N. Campbell**

P N Campbell is Director of the Courtauld Institute, Middlesex Hospital Medical School, London, UK.

Biochemical tools

Physical Biochemistry Applications to Biochemistry and Molecular Biology. By D Freifelder Pp. x+570 (Freeman San Francisco, 1976) Hardcover £12.40; softcover £8 00

A THOROUGH understanding of the physicochemical tools used by the modern biochemist is essential to their intelligent use It is unfortunately a common experience of many, if not all, teachers of physical biochemistry, however, that one of the major obstacles in the path of a diligent student is the labour necessary to wade through the often complex and seemingly endless theoretical and mathematical derivations which represent the standard approach to the subject One solution to this dilemma is to choose a limited number of techniques and to develop fundamental equations clearly from first principles with appropriate simplifications Such an approach is justified by the quantitative nature of many of the techniques and has been used successfully by K E Van Holde (also entitled *Physical Biochemistry*, Prentice-Hall)

An alternative and in some respects radical solution is to adopt an almost completely non-mathematical approach Professor Freifelder has done just this with the single aim of enabling "the student to understand and read the current literature" Equations cannot be avoided, of course, but although their derivations are, the physical principles, the assumptions behind the derivations and the conditions which must be satisfied for the equations to hold are clearly defined. *Physical Biochemistry* is therefore an exceptional book in that it neither requires nor contains a knowledge of basic thermodynamics which inevitably characterises other comparable texts. For this alone many students will be thankful

Throughout the book, Professor Freifelder's overriding concern is to stimulate the students' interest in the techniques of physical biochemistry, and if the avoidance of mathematical treatments is one cornerstone of his strategy, then the demonstration of the usefulness of the techniques in solving biological problems is the other Indeed, the outstanding feature of his book is the wealth of biological examples illustrated. The majority of these are drawn from the molecular biology of bacteriophages and the physical biochemistry of DNA and viruses, reflecting Professor Freifelder's research interests and making a welcome change from the more conventional protein examples

The subject matter is generally comprehensive, comprising an extensive section on direct observations by light and electron microscopy, general laboratory methods, separation and identification of materials, hydrodynamic methods including an especially well-written chapter on sedimentation, and spectroscopic methods including a useful introduction to nuclear magnetic resonance. The qualitative approach seems nevertheless to have led to some curious omissions for a text on physical biochemistry Thus all scattering techniques are absent In addition there is no treatment of multiple, small molecule binding Surprisingly, a section on immunological methods is included

This book is properly written for final-year undergraduate and first-year graduate students Many of them will appreciate its non-mathematical approach from which there are undoubtedly great advantages of motivation to be gained. Ultimately, however, the student who finally arrives at the practical application of a technique for his own research purpose can only benefit from a thorough acquaintance with the underlying theoretical and mathematical analysis This book will surely engender in the student sufficient enthusiasm to make the necessary effort **G. L. Kellett**

G L Kellett is Lecturer in Biochemistry at the University of York UK

Endocrinology of steroid hormones

Molecular Endocrinology of the Steroid Hormones By D. Schulster, S. Burstein and B. A Cooke. Pp.xv+321. (Wiley. London and New York; 1976) Cloth £9.75, $20, paper £4.75, $10.

THIS textbook on molecular endocrinology of the steroid hormones is an attempt to focus attention on the mechanism of action of steroid hormones. Its aim is to provide broad coverage with the minimum of fine detail in four main sections—methods, the endocrine glands, regulation of biosynthesis, and mode of action of steroid hormones.

The book is not intended to be a reference text for research workers, but is an account of steroid hormone biosynthesis and mode of action aimed at science students perhaps majoring in biochemistry, or at medical students There is no doubt that a science student with a reasonable background in chemistry and biochemistry could read this text with ease

The methodology of steroids is briefly reviewed with a fairly cursory treatment of radioimmunoassays. It might have been appropriate to have given this aspect of methodology a more extensive treatment. If the text is to be used by preclinical medical students then it is likely that most of the steroid hormone assays which they will request as practising doctors will be carried out using this method A detailed account of the technique including its shortcomings might have been to the reader's advantage

Biosynthesis of steroid hormones is presented in a fashion which will be acceptable to undergraduate science or medical students. Short chapters deal with the structure and function of the pituitary, hypothalamus, adrenal cortex, ovary, testes and the feto-placental unit. These chapters each contain a brief account of the structure and ultrastructure of the endocrine organ, its blood supply and its relationship to other tissues in the body. This section will be extremely useful to students from the physical sciences who wish to grapple with the concepts of endocrinology.

The third section of the book, which is concerned with the regulation of steroid hormone biosynthesis, contains three chapters, the largest being the control of corticoid synthesis by ACTH Problems associated with the acceptance of the usual dogma on the mode of action of ACTH are critically reviewed in this chapter. This is followed by a brief treatment of aldosterone synthesis and a short chapter on the control of androgen and oestrogen secretion by FSH and LH. In view of the considerable interest at the present time on the control of FSH and LH secretion, I would have preferred to have seen a more extensive treatment of the subject. For example, organic chemists and other nonbiological scientists in the pharmaceutical industry involved in work associated with contraceptive preparations could profitably read all of this book, but this section, which would be of great interest to them, is barely seven pages in length.

The production of even a short textbook involves a considerable gestation period The last section dealing with the mode of action of oestrogens, progestins and androgens covers topics which are currently under active investigation Most of the references contained in this section are to papers published pre-1975; because much work has emerged in 1975 and 1976, the medical or science students reading these chapters will be obliged to update the information. The basic concepts of the mode of action of steroid hormones, the localisation of the receptors and the possible nuclear events are constantly undergoing refinement and revision These chapters are superficial, but they will whet the appetite of the student, and the enthusiast will go on to read beyond this text.

It is regrettable that the mode of action of aldosterone does not receive a more detailed treatment. This is one of the few examples in steroid endocrinology where the investigator can in fact obtain a fairly precise physiological indicator of the action of the hormone in an *in vitro* system

This treatment of the endocrinology of steroid hormones will be welcomed by many teachers. The textbook will be valuable to students who are reading biochemistry either for a general degree or for an honours degree, and many of the problems associated with the interpretation of the mode of action of steroid hormones are highlighted Since the subject is so wide the treatment is superficial in parts; but it is always interesting, readable and relatively free from errors. The book can be recommended as a straightforward, clear account of the concepts of molecular endocrinology of steroid hormones in the mid-1970s

G. S. Boyd

G S. Boyd is Chairman of the Department of Biochemistry at the University of Edinburgh, UK, and Honorary Director of an MRC group on sterol metabolism.

Introducing prostaglandins

Prostaglandins An Introduction to their Biochemistry, Physiology and Pharmacology By P B Curtis-Prior Pp xi+158 (North-Holland Amsterdam, New York and Oxford; 1976) Dfl 42; $16 25.

THIS volume is intended as an introduction to prostaglandins for those "currently uninitiated in the subject" The author begins the main text by describing the nomenclature and biosynthesis of prostaglandins. I found the latter section rather misleading in parts—for example, the transformation of endoperoxides to prostaglandins is depicted (wrongly) as a reversible reaction Sections covering prostaglandin catabolism, inhibitors of biosynthesis and receptor antagonists, are followed by a chapter, entitled "Prostaglandin-like substances" (mainly polypeptides), which I felt did not really belong in the book at all The remainder of the text largely comprises an account of the effects of prostaglandins in physiological and pathological processes, although little was said about their role in the control of parturition, or platelet aggregation—surely two areas where the case for prostaglandin involvement is stronger than most? The final chapter deals rather perfunctorily with the important topic of biosynthesis of thromboxanes and other non-prostaglandin products of arachidonate

The text is produced by a process of direct photographic reproduction of the typescript, and the difficulties this causes in the arrangement of the figures give this (otherwise well produced book) a slightly unbalanced look. I found the quality of the artwork rather variable, mainly because half of the figures are reproduced from other sources, a practice which leads to trouble in the final chapter where the wrong structure of thromboxane A_2 is given.

This book is easy to read, but I found the chapters rather superficial and had the impression several times that the author was a little out of touch with the mainstream of prostaglandin research There is, however, no "primer" on prostaglandins to which the "uninitiated" can refer, and no doubt many will be glad to find this information collected in a basic text The book contains adequate references for further study

R. J. Flower

R J Flower is a research pharmacologist within the Wellcome Foundation, Beckenham, Kent, UK

Enzymes and cellular metabolism

The Enzyme Molecule. By W. Ferdinand. Pp. xvi+289. (Wiley: London and New York, 1976.) Cloth £9.50, $20; paper £4.50, $10.

THE study of enzymes is often regarded as being an end in itself rather than being an essential step towards an understanding of the way in which the cell functions and regulates itself as a biochemical entity. This book makes a valuable contribution to setting the study of enzymes in the wider context of cellular metabolism. The book, which is intended for undergraduate students, requires little initial biochemical knowledge from the reader, although some elementary mathematical ability is assumed.

The topics of simple thermodynamics, single-substrate enzyme kinetics, enzyme purification and protein structure and chemistry are dealt with in some detail in the earlier chapters and an appendix of the book. These chapters lay a solid foundation for the discussion of enzymes which occupies the remaining two thirds of the book. A chapter on enzyme structure and function covers the measurement of ligand binding, determination of residues at the active site, conformational changes in proteins and mechanisms of enzyme catalysis. This last section provides a clear and readable account of transition-state theory which should provide an excellent introduction to those wishing to take the subject further. The author has chosen to consider a single enzyme, ribonuclease, as an example of the chemical mechanism of enzyme action, and the account presented provides a good summary of the evidence which has led to current theories of its catalytic mechanism.

The effects of inhibitors, activators, *p*H and temperature on enzyme activity are covered in a single chapter occupying some fifty pages, which also includes a treatment of the kinetics of enzymes using two substrates. The attempt to cover such a wide range of topics in a relatively short space has led to a rather uneven treatment. The effects of *p*H and temperature on enzyme activity are given rather brief and superficial treatments, whereas the discussion of the Wong and Hanes method for deriving kinetic equations is excellent. In the consideration of the kinetic mechanisms of two-substrate enzymes the author's prejudices do not always coincide with those of the reviewer and generally this section concentrates upon nomenclature to too great an extent without considering the underlying causes of the observed kinetic effects. Cooperativity and allostery are considered in a separate chapter which makes a clear distinction between these two phenomena and discusses the major models of cooperativity and the kinetic predictions that they make. Aspartate transcarbamoylase is chosen as an example of an allosteric enzyme for detailed discussion and the author provides a lucid account of a somewhat confusing situation.

The first chapter of this book considers the role of enzymes within the cell and this topic is returned to in the final two chapters which discuss the role of enzymes in the control of metabolism. One of these chapters provides a somewhat brief outline of the factors affecting the control of enzyme concentration in the cell, whereas the other is an account of the kinetics of the regulation of metabolic pathways. This chapter provides an excellent account of how the enzyme kinetic theory considered earlier can be applied to the regulation of metabolic pathways within the cell. It should be required reading for all those who believe that the study of enzyme kinetics is an end in itself.

An important omission from this book is that there is no treatment of the kinetics of the transient phases of enzyme reactions. The author has obviously had to be selective in his choice of topics in order to deal with the study of enzymes in a relatively short space, but the lack of any treatment of this topic restricts the value of the book as a general introductory text on enzymology. Shortage of space has also lead to a somewhat cryptic presentation of some topics such as X-ray crystallography and experimental methods for studying ligand binding. In addition the author occasionally makes categorical statements that should require qualification For example, it is asserted that the initial rate of enzyme-catalysed reactions is always proportional to enzyme concentration whereas there are in fact a number of exceptions to this and workers should be encouraged to check for such linearity rather than just assuming it.

Despite the above reservations this book provides a good introduction to the study of enzymes and should prove valuable to many students, particularly in showing how this topic relates to the wider fields of biochemistry and cell biology.

Differing approaches to genetics

SINCE a knowledge of genetics is now considered an important ingredient of many undergraduate courses, as widely disparate as molecular biology and sociology, very different approaches to the subject are to be expected. This is reflected in several undergraduate texts which have appeared in the past year.

M. I. Lerner and W J. Libby's *Heredity, Evolution and Society* (Freeman San Francisco, second edition, $13 95; £8.80) is concerned more with the social consequences of genetics, although it would be unfair to suggest that the authors have neglected the scientific basis of the subject. The emphasis throughout is on the relationship between genetics and evolution, particularly human evolution. Yet though largely, but not exclusively, concerned with human genetics the text is not over-burdened with obscure clinical references which often reduce the appeal of such texts to science students. The standard arrangement of most student textbooks of genetics is not followed For example, chromosome structure and function are not dealt with as such but are included in chapters on gene interaction, sex and mutation. An attractive feature of the book is the use of inserts, called 'boxes', in which are segregated most of the descriptive, biographical and tabular material This is a clearly written text which is eminently readable.

Many biologists are daunted by genetics because of the emphasis on statistics D. T Suzuki and A. J. F. Griffiths recognise this problem, and their book, *An Introduction to Genetic Analysis* (Freeman San Francisco, $13 95) ". . . attempts to teach the reader how *to do* genetics". This is therefore not strictly a textbook, for it is not just concerned with concepts but is more a guide as to how to analyse genetic data. The approach is essentially quantitative, although a level of mathematical sophistication no greater than simple algebra is required It is clearly meant to be a didactic text, extensive use being made of a question-and-answer format, problem-solving exercises (a separate book of answers is available), and the dispersal within the text of so-called "messages" which summarise important information. There are also sequences of diagrams illustrating mitosis, meiosis, DNA replication and translation which can be animated by letting the pages flip over This latter device is not really very satisfactory and seems out of place in a University text Quantitative problems in all aspects of genetics are considered including Mendelian segregation, linear and circular linkage analysis (but not lod score methods), cytogenetic mechanisms and mutation. There is also a chapter on population genetics. Perhaps it is in this latter field that mathematical analysis has been most important, yet this is given relatively little attention The book is wide ranging in the material chosen to illustrate problems in genetic analysis, but it is difficult to see how it will survive competition with more conventional texts.

N. V Rothwell's book *Understanding Genetics* (Williams and Wilkins Baltimore, $14.95), is perhaps the most conventional of these texts. It deals in the usual manner with the mechanisms of gene action, cytogenetics, various aspects of biochemical genetics and population genetics. The molecular basis of inheritance is dealt with very well indeed but rather oddly is relegated to the latter half of the book. This text provides a straight-forward account of genetic mechanisms illustrated by examples from widely related organisms. The illustrations are simple straight-forward line drawings which are very attractively presented. Each chapter concludes with some well chosen references, although very few of these are more recent than 1970 Apart from the chapter on probability there are no student exercises.

W. Hexter and H T Jost's *The Science of Genetics* (Prentice-Hall Englewood Cliffs, New Jersey, £11 90, $18 95) is also an introductory text designed primarily for biology students, but here the authors have tended to use a historical approach in order to emphasise the reasoning which initiated critical studies and lead to important conclusions. The hope is that the book will have a two-fold purpose. " . to introduce the student to the essential facts of genetics and to introduce the student to the methods of science". In general the authors have been successful. Again, illustrative examples are widely chosen from both the plant and animal kingdoms. Of student texts which deal primarily with the science of genetics, this is perhaps the most readable and exciting, probably because of the emphasis on the evolution of concepts and ideas. It also becomes quite clear where there are still some major gaps in our knowledge and understanding, as in the case of chromosome structure The book is enhanced by simple straight-forward line drawings and with references to key papers. Each chapter concludes with a number of exercises but no answers are provided.

These four books therefore reflect very different approaches to genetics For those whose main interest lies in human problems and the social consequences of genetics, Lerner and Libby's book can be unreservedly recommended For those who want a more standard undergraduate text of general genetics, Hexter and Jost's book is perhaps the best.

Alan E. H. Emery

Alan E. H. Emery is Professor of Human Genetics at the University of Edinburgh, UK.

Abundant facts of immunology

Basic and Clinical Immunology. Edited by H. H. Fudenberg, D. P. Stites, J. L. Caldwell and J V. Wells Pp. 653. (Lange Medical Publications Los Altos, California, 1976) $12.50.

THIS large book is good value for money. Its intent is to act as a source from which the enquiring mind may obtain the abundant facts of immunology. There are impurities in this spring of knowledge some of which should disappear in the promised biennial revisions. The editors solicit our specific advice on this point.

The tone of the book is authoritarian and the referencing is inadequate to check the origins of many of the statements made This may be in line with the current teaching of medical students but it is irritating for the more curious reader The indexing is capricious, which is probably inevitable in a book with forty chapters written by many different people. The line drawings are first class but the reproductions of photographs are in the main of indifferent quality.

The first half of the book deals with the basic aspects of immunology starting with a delightful chapter by Grabar on the historical background The short chronology on important achievements in immunology, which terminates this particular piece, ends at 1959 at a time when many might think immunology was just beginning to gather steam.

The second half of the book starts with a summary of the methods in common use in immunodiagnosis and concludes with a series of chapters on clinical immunology.

The book is fascinating and reminiscent of Florey's texts on general pathology My reservations simply concern the difficulty of teaching rapidly changing subjects without perpetuating too many errors **A. J. S. Davies**

A. J S. Davies is Professor of Immunobiology in the University of London, working at the Chester Beatty Research Institute, London, UK.

CONFERENCE REPORTS . .

. . . a new conception

CONFERENCE REPORTS is an information service produced in four journals embracing the entire spectrum of science and technology. It is concerned purely with the reporting of scientific conferences throughout the world and is published under the following titles:

- **Physical and Chemical Sciences**
- **Engineering, Technology & Applied Sciences**
- **Agriculture, Food and Biology**
- **Medicine**

SEND FOR A FREE ISSUE
of the section of interest to you

Reports appearing in the journals commence with an account of the proceedings followed by details of any published material available. The papers presented and their authors are then listed, and the report concludes with useful addresses for further enquiries.

Many specialists require reports of conferences which lie on the periphery of their own field of study. However, such conferences have not always been adequately reported to them. CONFERENCE REPORTS eliminates that deficiency by enabling the specialist to become conversant with the latest events and developments in his own and related fields.

CAMBRIDGE UNIVERSITY PRESS

The Evolution of Reproduction
Edited by C. R. AUSTIN and R. V. SHORT

Reproduction in Mammals is a series designed as a basic undergraduate text. It is written in a lively style, copiously illustrated and published in six slim volumes. This, the sixth volume on the *Evolution of Reproduction*, ventures into a new and important area of biological thinking, and examines the many influences that have played a part in the development of mammalian reproduction.

Reproduction in Mammals 6 **Hard covers £6.50 net**
Paperback £2.50 net

Plant Variation and Evolution
D. BRIGGS and S. M. WALTERS

A textbook on plant variation and evolution for undergraduate biologists

'This really excellent book is, I think, quite the best short survey I have ever seen . The text is lucidly and easily written, excellently illustrated and the volume beautifully made and printed . There is no better elementary introduction to a subject of central biological importance.' *Journal of Ecology*

Paperback £2.95 net

This edition is not for sale in the USA and Canada

Foundations of Mathematical Genetics
A. W. F. EDWARDS

A definitive account of the basic models of population genetics, with the subsidiary purpose of giving the historical origins of developments since 1908 Although written primarily for those professionally interested in the mathematical aspects of genetics, ecology and biology generally, advanced students in mathematical genetics will also find it complementary to the established textbooks **£5.80 net**

The Ecology Game
MICHAEL A TRIBE and DEREK PEACOCK

A simulated research exercise on an ecological topic for sixth-formers and undergraduate biology students working in groups. The material consists of 110 data cards, index and grant cards, six student instruction leaflets and tutor's booklet giving full instructions, all presented in a ring-bound folder. The game could be particularly useful as a substitute for, or extension of field work

Basic Biology Course **Game Pack £10.00 net**
Film Strip £6.50 + VAT

Tropical Soils and Soil Survey
ANTHONY YOUNG

A book about tropical soils written from the point of view of the field soil scientist. Whilst primarily directed at those concerned with, or training for, field studies of soils in the tropics, the book will also be useful to non-specialists who wish to understand the significance of soils in agriculture and economic development.

Cambridge Geographical Studies No. 9 **£15.00 net**

Paperback edition

Applied Geophysics
W. M. TELFORD, L. P. GELDART, R. E. SHERIFF and D. A. KEYS

A comprehensive textbook of exploration geophysics that describes the various methods available for locating deposits of oil, natural gas and minerals A valuable work of reference for exploration geophysicists and a textbook for students at the graduate level.

'The book is a very good one, written and illustrated with clarity ' *Nature*

To be published on 24 March **Paperback £9.75 net**

Vector Fields
Vector Analysis Developed through its Applications to Engineering and Physics
J. A. SHERCLIFF

A field is a distribution in space of physical quantities of obvious significance, such as pressure, velocity or electromagnetic influence. This textbook for students of engineering, physics and applied mathematics develops the mathematical ideas necessary to handle fields and provides a core course showing how the same mathematical ideas can be used in a wide range of different physical contexts

Forthcoming (March) **Hard covers £13.50 net**
Paperback £4.25 net

Electric and Magnetic Fields
An Introduction
SIR CHARLES OATLEY

This book presents an introduction to electromagnetic theory based on the author's ten years' experience in lecturing in the subject to engineering students The emphasis throughout is on physical principles and it is suitable for first- and second-year students studying engineering and physics.

Electronics Texts for Engineers and Scientists **Hard covers £9.75 net**
Paperback £3.50 net

Vector Analysis
A Physicist's Guide to the Mathematics of Fields in Three Dimensions
N KEMMER

A book in which Professor Kemmer brings a novel approach to the subject which while maintaining mathematical precision, the methodology of presentation relies greatly on the visual, geometric aspects of the subject and is supported throughout the text by many beautiful illustrations. Whilst intended primarily for undergraduate physicists, the book is equally appropriate for engineers. engineers.

Hard covers £12.00 net
Paperback £3.95 net

Principles of Cosmology and Gravitation
MICHAEL BERRY

This book presents modern scientific cosmology and Einstein's theory of gravitation at the undergraduate level, thus filling a gap in the literature It has been designed as a cosmology course text for undergraduates, for research students starting work on cosmology who require a preliminary orientation and for every physicist who wants to learn about current work in cosmology and gravitation.

Developing biologists

The Developmental Biology of Plants and Animals, edited by C. F Graham and P. F Wareing (Blackwell Scientific Oxford and London, £7 75; Saunders Philadelphia), is unusually courageous for a textbook in treating development as a biological problem, not simply as zoology or botany. This approach has clear gains (for example, cell interactions and control of differentiation) but also losses a selection of topics that "have a bearing on general themes of plant *and* animal development" (my italics) inevitably excludes many of relevance to only one or the other. On the animal side, the book has nothing on extraembryonic membranes and, more seriously, next to nothing on cell movements.

The book is in six parts, most with an introductory chapter and short conclusion by the editors. Individual chapters are by 20 different authors, mainly writing from British laboratories (except J. T. Bonner from the USA). Integration is achieved by extensive cross-referencing. Figures are used sparingly, giving us a lot of text for our money. The book is advanced, not introductory: most chapters assume basic background, and some use an eclectic range of examples and terminology that would soon baffle a beginner.

In a book of this scope, an individual is bound to have both praise and grumbles over facts or emphasis. Many chapters seem to me admirable critical summaries of our present knowledge—those on animal cell junctions and the control of gene expression are especially clear. On the other hand, the emphasis of the chapter on "self-assembly" seems misplaced. There is lots of physical chemistry, but very little on regulation, surely the central issue for developmental biologists. "Pattern formation in animal embryos" is not for the unwary, reading simply for information: it suggests short-range inductions rather than gradients or positional information as the basic mechanism—a stimulating article, belonging more in a journal than a textbook. The section on environmental effects (rarely mentioned in accounts of animal development) disappoints me. Although most work has been on model animals in laboratories, emphasising the constancy of developmental processes, information is now appearing on ecological factors (for example, on the timing of amphibian metamorphosis), but none of this is mentioned.

Some small points: a student ignorant of *Ascaris* might get the impression that chromosome diminution never occurs (p302). Is vertebrate limb elongation "entirely due to addition of tissue at the tip" (p180)? Why no mention of Roth's (1973) hypothesis as a mechanism of cell interactions (chapter 3 1)? And two irritations: tubulin repeatedly spelt tubullin (p259); reference lists at the end of each chapter, some in alphabetical order, others not, rather than altogether at the end.

Do advanced students need a textbook? Many courses prefer directed reading in the original literature and reviews, since ageing is rapid in the subjects covered here. Although the cover date is 1976, the book's literature survey just scrapes into 1974, comparing unfavourably with its most direct competitor, Lash and Whittaker's *Concepts of Development* (Sinauer, Stamford, 1974), almost as up-to-date, despite its earlier publication. The incompleteness makes the book less than ideal for either botanical or zoological courses) still in the majority?). Students may simply regard the 'irrelevant' chapters as money down the drain.

Despite these general doubts, and a few grumbles about details, I'd still heartily recommend this book for the excellence of many of its chapters, for its thoughtful overall philosophy, and for those sections which include examples from both kingdoms—they'll make biologists of us yet!

I cannot so easily recommend John McKenzie's *Introduction to Developmental Biology* (Blackwell Scientific: Oxford and London, £4.25; Halsted/Wiley: New York). This takes the view that students need to be cajoled into an interest in development by examining human development first. This may be true of medical students, but not, in my experience, of biologists. For an introduction, the book has too many unexplained anatomical terms (no glossary) and minor errors.

J. R. Downie

J R Downie is Lecturer in Zoology at the University of Glasgow, UK.

Recipe books for crop production

Crop Production: Principles and Practices by S R Chapman and L. P. Carter (Freeman San Francisco, $15) is one of several similar books that outline the production of crops in the United States. All of them profess to introduce the principles of crop production before detailing the growing procedure for the major crops. For example, in this book by Chapman and Carter "Our philosophy has been that modern highly productive farming practices depend on an understanding of the principles of plant growth. When the principles are grasped, the practices follow logically." This is a commendable philosophy for the teaching of undergraduates in agriculture, but when a closer look is taken at these introduction principles (approximately half of the book) we find, in spite of a beautifully illustrated text, a rather thin veneer of elementary botany covering once again mitosis and meiosis, simple plant morphology, properties of soils, and so on which seem too common an occurrence in so many agricultural textbooks that try to cover too much material. To give two examples, where are the principles relating economic crop yield to plant density, which can explain seeding rate and crop establishment practices? and where are the principles of fertiliser response curves on which all fertiliser recommendations need to be based? As our present knowledge of field crop physiology gives a clearer understanding of many common crop practices throughout the world, it should now form the basis of crop production textbooks.

The second half of the book deals with production practices for each crop in the form of a growers' manual. This may be a useful source of reference, but one hopes that present undergraduates are not expected to learn and inwardly digest the factual details of crop-growing procedures. A further indication of thin coverage, is the allocation of only six pages of text to the maize crop, particularly since the crop originates from a country that produces 40% of the world's production.

In contrast, the latest edition of *Principles of Field Crop Production* (Collier-Macmillan, London, £7) by Martin, Leonard and Stamp gives some five times this coverage and would provide a better reference source. But in the final analysis, the recipe book approach to crop production makes this type of textbook no more effective than a farmer's manual for the country of origin. How, for example, does a University level agronomist, who has been reared on such a diet, adapt to unfamiliar environments, such as the third world, without an understanding of the principles of field crop growth?

G. M. Milbourn

G M Milbourn is Senior Lecturer in Crop Production at Wye College, University of London, UK.

Microbial physiology . . .

Microbial Physiology (Basic Microbiology, Vol 4.) By I. W Dawes and I W Sutherland, Pp v+183 (Blackwell Scientific. Oxford and London, 1976) £4.25.

MICROORGANISMS can do so many things and can do some of them in so many different ways, consequently it is hard to give a short introductory account of microbial physiology which retains clarity and precision while covering a representative, if not comprehensive, range of material. The choice of topics in this book is judicious, but the coverage of them is somewhat uneven

The first chapter is a concise account of the structure and organisation of both eukaryotic and prokaryotic microbial cells with a useful digression on flagellar function This is followed by a chapter on the growth of cells and populations. Although the cell cycle and its relation to both production of new cell surface and DNA replication are well described, the part on growth of batch and chemostat cultures is rather slight A discussion of cell death and the mode of action of some antimicrobial agents is, however, included

The third chapter, "Substrate entry into the cell", prefaces four chapters on microbial biochemistry Energy production in heterotrophic organisms is covered in reasonable detail, and this is followed by a description of photosynthesis which is the worst part of the book, as it is not a particularly clear account, including an odd choice of detailed information and some unfortunate errors Equally, the chapter on monomer biosynthesis is patchy Some anaplerotic sequences are described in good detail, but it is not possible to deduce, for instance, how an organism might grow with succinate as sole carbon source The choice of biosynthetic pathways and their description on the other hand makes pleasant and informative reading

The next two chapters on macromolecular synthesis and the control of metabolism are also well done in general The concluding chapter is concerned with morphogenesis, showing the importance of this sort of phenomenon for microbiologists and what marvellous experimental systems microorganisms can provide for the study of a variety of morphogenetic problems

The standard of production of this book is fair the print is rather small but the text is divided by frequent subheadings There are plenty of illustrations, most of which are informative, although they vary in style and precision Thus, the effect of temperature on the growth rate of *Escherichia coli* is shown as an Arrhenius plot with fully described scales and with data points (which is good), whereas the induction of β-galactosidase by isopropylthiogalactoside is shown as a sketch graph without scales or data points, and is actually incorrect (which is bad)

The further reading suggested also leaves something to be desired Two to five review or textbook references are given for each chapter, but these do not always cover enough material For chapter two, there are no references on population dynamics and asynchronous culture techniques, although three references to cell cycle literature are given

This book may be of use for microbiologists in the early stages of an undergraduate course and as a concise survey for students of biochemistry and genetics. I think it is poor value for money at its present price.

C. F. Thurston

C F. Thurston is Lecturer in Microbiology at Queen Elizabeth College, University of London. UK.

. . . genetics . . .

Two recently published books on microbial genetics, aimed at first- and second-year undergraduates, cover essentially similar material, which can be broadly described as the organisation, function and recombination of bacterial and viral chromosomes and the molecular basis of gene action The emphasis of the two books is, however, very different. About 30% of D M Carlberg's *Essentials of Bacterial and Viral Genetics* (Charles C Thomas Springfield, Illinois, $24.75) is devoted to an interesting account of mutation and a further 30% to recombination systems in bacteria and viruses. About 40% of the new edition of J R S Fincham's *Microbial and Molecular Genetics* (Hodder and Stoughton: London, hardback £3.95, paperback £2.25, Crane, Russak New York), on the other hand, provides useful summaries of gene action, regulation, plasmids and DNA technology Fincham follows the now traditional sequence of the properties of DNA, chromosome mapping and mutation followed by the topics already mentioned, whereas Carlberg covers protein synthesis, regulation and mutation before basic features of genetic systems which inevitably results in a degree of cross referencing

As an introductory text Fincham's book suffers from not being self-contained Some of the basic material on chromosome mapping and bacteriophage biology is not clearly explained. For example, it is not very helpful to provide ascus analysis data from a four-point cross in *Neurospora* together with a bald statement in the text that "Table 2 illustrates the principle" (p31) It is also difficult to understand why there are no diagrams of the lytic and lysogenic cycles of bacteriophages when there are diagrams of life cycles of *Neurospora* and yeast, organisms covered in only a minor part of the book Another topic which lacks diagrams is the mechanism of sex factor insertion and chromosome transfer in bacteria In the preface the author hopes that the book will not be beyond the "ambitious beginner" in biology but one might add to that the "intelligent beginner", as I do not feel that this is the book to guide the average student through these aspects of genetics Although the author provides selected textbooks and original articles for advanced students he does not really cater for elementary students working at this level Reference to articles in *Scientific American*, *Science Progress*, *Science*, *New Scientist* and the *British Medical Bulletin* would have been more appropriate

Carlberg deals with his subject matter rather broadly and includes some interesting material on industrial and medical applications of microbial genetics His style is essentially that of a lecturer giving an outline of the material but "leaving much fine detail for the interested student to seek out in the literature" This approach has much to recommend it as the book is readable, interesting and clear, but it has the disadvantage that the book cannot be used to provide the detail usually expected in a course text

Carlsberg's book is more lavishly produced, which is reflected in the price. The diagrams, many of them original, are on the whole clear but some are below the standard expected For example, the drawing of an icosahedral virus on p286 is inadequate, the models for recombination are not good, and a diagram on p193 shows a diploid cell with a haploid chromososome number It is also surprising to find no mention of bidirectional replication of DNA The inclusion of a patent application is interesting but it is difficult to see the justification for the inclusion of ten pages rather than an abstract of the important points.

Neither book attempts to be fully up-to-date in controversial areas, such as molecular mechanisms for recombination, so that the material included should not date too rapidly It must be recognised, however, that most genetics texts only have a useful life of a few years Neither book can be strongly recommended for use as course texts although Carlberg's might be suitable for particular types of courses Its price, however, would prevent its purchase as a standard text For students studying genetics as well as microbial genetics, a more sensible purchase would be the second edition of M W Strickberger's *Genetics* (Collier-Macmillan : London, £6.30+0.95 pence for answer manual).

Bacterial, Phage and Molecular Genetics. (Springer Berlin and New York, DM23; $9 50), a practical manual by U. Winkler, W Ruger and W Wackernagel, translated from the German, is a very useful collection of experiments which complement well the manuals already available There are a range of experiments on the purification of bacteriophages as well as detailed schedules on density gradient centrifugation techniques Molecular aspects include the isolation and analysis of DNA from bacteriophages as well as experiments on mRNA. The use of ultraviolet light, one of the safer mutagens, is fully exploited to show lethal effects, mutagenesis and the induction of lysogenic and colicinogenic bacteria. Standard bacterial and bacteriophage genetics experiments are included as well as transfection of *Escherichia coli* sphaeroplasts with λ DNA. The final section deals with gene action and phenotypic expression with systems ranging from morphopoesis in T4 bacteriophage to regulation of β-galactosidase In addition to schedules for 25 experimental areas there are also brief introductions to background theory, useful references, five sets of problems and answers and (particularly valuable) 48 pages of the results expected from the experiments described.

This manual should prove very useful to lecturers attempting to broaden the range of experiments in microbial genetics courses. The book is clearly produced and usefully illustrated with graphs and specimen data sheets The experiments described are not as ambitious as some of the recent manuals on molecular genetics but this has the advantage that most of the experiments should be feasible in a department with average equipment.

B. W. Bainbridge

B. W Bainbridge is Senior Lecturer in Microbial Genetics at Queen Elizabeth College, University of London, UK.

. . . and ecology

Interfaces in Microbial Ecology. By K C Marshall. Pp. x+156 (Harvard University . Cambridge, Massachusetts, and London, 1976) £9.40.

PROFESSOR MARSHALL has written a book that is attractive to read, and which is concise, selective, and clearly written Microorganisms living at interfaces do so in a peculiar habitat; they are faced by unusual physicochemical stresses and must live a very different life from that of the bulk phase organism What then do we hope to learn from a book that introduces us to the microbial ecology of this habitat?

The history of physical chemistry abounds with studies on the properties of interfaces, there are also clear ecological distinctions between gas–liquid, gas–solid, and liquid–solid boundaries; living bacteria exist in all environments and so must encounter such interfaces regularly. Topics of this sort are fundamental enough to need careful definition and discussion in an introductory text. Professor Marshall does precisely this, guiding us adeptly through some fairly advanced physical chemistry in the first few chapters, being careful to define his symbols as he does so.

Later chapters are concerned with "non-specific interfacial interactions in aquatic and terrestrial environments" and "specific interfacial interactions in microbial ecology". Although some workers may not be convinced of the need for this distinction, Professor Marshall's treatment of aquatic and terrestrial environments is stimulating and provokes one to further research He discusses the nature of bacterial adhesion, the problem of nutrients at surfaces, and the habitat of sedimentary microorganisms, and considers such terrestrial topics as moisture content, the rhizosphere and mineral dissolution In his final chapter Marshall comments on the characteristics of oral and intestinal microorganisms, and lists some other microbial curiosities all of which prove entertaining.

Technically, the book is well produced, and the typographical layout is clear Almost all of the figures and tables serve to amplify the text, except perhaps Fig 1.1 and 5.6, both of which suffer from being reproduced on matt paper. The bibliography is representative and the only fault I could find in the text was unfortunately a reference to my own work with Professor Crisp, which I thought was slightly irrelevant in a paragraph on primary microbial films (p61).

In general, I found Professor Marshall's book easy to read systematically, as well as being enjoyable to dip into, and can recommend it to advanced undergraduates and postgraduate research workers

P. S. Meadows

P S Meadows is Senior Lecturer in the Department of Zoology at the University of Glasgow, UK.

Pocket guide to practical genetics

Methodology in Medical Genetics: An Introduction to Statistical Methods. By Alan E. H. Emery. Pp 157. (Churchill Livingstone: Edinburgh, London and New York, 1976.) £6.50.

THIS is a compact little book (I have reviewed it bit-by-bit, carrying it around in my pocket), clearly printed and well produced. The style is painstakingly explicit, missionary in tone, and unpretentious in its objectives and exposition.

The scope might fairly, and with no slight, be described as a compilation of those methods which Professor Emery, a practical human geneticist of extensive experience, has himself used. They comprise: standard segregation analysis (including some of the newer methods not covered in the classical texts); linkage analysis with and without the Bayesian modification; principles, but not details, of genetic counselling; twin studies, quantitative methods; and some of the elements of population genetics. There are many tables of wide utility, at present eclipsed by the computer, but (if our grants remain unfunded) likely to undergo a revival.

The author's unwavering practicality spares us the pages of pettifogging middle-grade mathematics which to the eyes of mathematicians and non-mathematicians alike, blight so many books on analytical genetics. His practicality is also a weakness. A really good mathematician with a true desire to communicate to the non-expert would have produced a somewhat more illuminating book. Here there are no underlying statistical principles stated: methods are produced with no visible means of support. Maximum likelihood estimation (MLE) is used, but we are told nothing of its properties, a neglect which has its counterpart in some of the methods chosen. For instance, there seems scarcely any point now in the Lenz–Hogben method which has never been well defended (for example, as to the asymptotic normality of the test statistic), is not based on a sufficient statistic, and falls far short of maximal power. On the other hand the MLE method recommended for the frequency of a rare recessive gene is so badly biased as to merit a jack-knife correction; in small samples it far from follows a normal distribution, a property implicitly invoked on page 5. (A Poisson approximation with confidence limits based on the χ^2 distribution would have been preferable.) Again MLE of θ, the recombinant coefficient, is so biased for large θ as to make estimation of loose linkage hazardous in anything but immense samples: thus it scarcely matters what, if any, mapping function is used.

These defects are likely to leave the student, nurtured on this book alone, with little statistical sense and without either inventiveness or resourcefulness. This trend shows up in the method recommended for estimating the frequency of an X-linked recessive gene, which discards all information on female subjects. (Numerical MLE is straightforward, if a trifle inelegant.) The ABO problem is dealt with by Bernstein's method, which is absolutely efficient asymptotically but which would not be so for four alleles or more.

I am afraid, however, that few biologists are mathematically adventurous. No doubt Professor Emery knows his audience at least as well as I do and caters for them appropriately. With a good, well-informed, teacher as a safeguard, this book might be successfully used as an elementary text, and many more sophisticated geneticists would be happy to have it in their pockets for ready reference.

Edmond A. Murphy

Edmond A. Murphy is Professor of Medicine at Johns Hopkins University, and Director of the Division of Medical Genetics at the Johns Hopkins University School of Medicine, Baltimore, Maryland.

Integrated text on population biology

Population Biology. By Thomas C. Emmel. Pp xii+371. (Harper and Row: New York and London, 1976.) £11.95, $15.95.

As the author remarks in his preface, "part of the problem of writing a book on population biology involves the host of inter-relationships among the basic contributing fields of ecology, genetics, evolution and behaviour". Dr Emmel copes well with this problem, providing a clearly arranged up-to-date account for the "well-prepared, advanced undergraduate". The book would also serve the professional biologist needing to catch up with some aspects of this recently integrated subject.

The chapters deal with cycles of matter and energy, population genetics and evolution, population dynamics, dispersion, dispersal, age and sex structure of populations, life-history patterns, mating systems, behaviour, climatic effects, and interactions of populations in communities. The reference list of 1,400 or so items is strong on recent contributions, and the index is reasonably comprehensive. The illustrations are on the whole excellent, although a few of the line drawings are disproportionately tall, and several of the half-tone pictures fall short of their purpose—the zebras in 11-14 do not appear cryptic, whereas the cicadas in 8-2b do (but should not).

In a fairly advanced book presenting many modern ideas and examples, workers in this field will inevitably find things to disagree with, and also errors. We are told on p222 that populations emphasising *r* selection typically inhabit regions with variable climates, such as the temperate zones, and on p224 that most terrestrial vertebrates and perennial plants seem to be *K* selected, whereas most annual plants and insects are apparently *r* selected. The joint consequences of these two generalisations might well startle a biogeographer. Only later are we warned of the uncertainties of *r* and *K* selection theory.

Most of the errors I noticed were minor misprints, an omission of a text citation from the reference list, and so on. I regard the original meaning of "decimate" and the proper spelling of "repellants" (noun) as lost causes, but hope we may save *Rhagoletis* from being confused (p60) with the "frit" flies. More serious is the confusing blunder in Fig 5-16, in which the prey curve is labelled "predator", and *vice versa*. On p229, the net reproduction rate R_0 is said to be the number of surviving offspring per female; it should be female offspring. On p53, one of the equations for intensity of natural selection is badly misprinted.

Although the material, like the subject itself, is predominantly American, examples are taken from many parts of the World, including Britain. Some of the examples cited are difficult to present briefly, and in places (for example, pp137–8) the exposition is not clear enough.

To a British reader it seems odd to find no mention of life-table analysis and *k* factor analysis for diagnosing 'key factors' and density relationships among the successive mortalities in the life-cycle. If this (as it seems to me) is a serious omission, it is an exceptional feature in this generally comprehensive and well-balanced account. With its stimulatingly up-to-date treatment, I should think it worthy of a place in the short-list of books for students of population biology.

M. E. Solomon is Head of the Zoology Section at Long Ashton Research Station, University of Bristol, UK.

New and Forthcoming Titles from Longman

PRACTICAL PLANT PHYSIOLOGY
J Roberts and D G Whitehouse

This text provides a range of tests and experiments in plant physiology and biochemistry useful to schools and first-year university students

The experiments, which are designed for those operating on a limited budget, cover the whole field of plant physiology, avoiding as much as possible duplication of earlier texts quoting well-established experiments To encourage students to consider variations utilising the techniques and principles introduced, suggested project work and additional experiments are provided at the end of each chapter. SI units are used in almost all cases, but conversion tables are provided in an appendix.

Paper £4.95 net

THE METALLIC ELEMENTS
R V Parish

Written for first and second year degree students, this book deals with the systematic chemistry of the metallic elements. Dr Parish combines an account of the descriptive chemistry of all the elements with explanations of the observed patterns of behaviour, wherever possible, in terms of the fundamental properties of the atoms, ions, and bonds involved For conciseness and uniformity, coverage is restricted to the halides and oxides and the aqueous solution chemistry for each set of elements. The preparation, properties, structures and relative (thermodynamic) stabilities for each of these systems are treated in some detail and the trends common to each group are brought out. An introductory treatment of coordination chemistry and crystalfield theory is also given. SI units are used throughout.

Publication April 1977

Paper probably £7.00 net

INTEGRAL EQUATIONS
B L Moiseiwitsch

An introductory text on integral equations for undergraduate students of mathematics and mathematical physics in their final year of an honours course

This book is mainly concerned with linear integral equations. It begins with a straightforward account of the subject, accompanied by simple examples of different types of integral equations and the methods of their solutions, but goes on to provide a rather more abstract treatment with a discussion of linear operators in Hilbert space

Paper £3.95 net

★Introduction to Environmental Remote Sensing

E. C. BARRETT AND L. F. CURTIS

This text is designed to provide an introduction to modern remote sensing techniques and applications. It gives a comprehensive account of the methods and equipment used for remote sensing studies. The book also provides a comprehensive coverage of the many applications of the techniques including their use in meteorology, climatology, the study of landforms, forestry and urban studies.

December 1976 346 pages Science Paperback £5.95

★Multivariate Analysis in Behavioural Research

Monographs on Applied Probability and Statistics

A. E. MAXWELL

This introductory book is mainly concerned with the classic techniques of multivariate analysis, but, throughout, special attention is directed to the disruptive role which errors of measurement in observations can play when various techniques are employed, and to possible ways of assessing the effects of such errors.

February 1977 176 pages Limp £3.95

OUTLINE STUDIES IN BIOLOGY

★A Biochemical Approach to Nutrition

R. A. FREEDLAND AND S. BRIGGS

The main objective of *A Biochemical Approach to Nutrition* is to provide readers with an appreciation of the influence of nutrition on metabolism and metabolic controls. The book ranges from detailed discussions of regulation metabolism to general aspects of present day nutritional concern.

10th March 1977 64 pages £1.50

★Plant Cytogenetics

D. M. MOORE

This book outlines the theory of inheritance and the role of chromosome studies with reference to plant material.

Feel for biological rhythms

An Introduction to Biological Rhythms. By J D Palmer With contributions by F A Brown, Jr and L N Edmunds, Jr Pp. xvi+373 (Academic. New York and London, August 1976.) $19 50. £11 90.

THE author describes this as an introductory book, pitched at a level between popular books and technical treatises, these two stools are difficult to bridge The enquiring student, to whom it is in part addressed, might find it difficult to evaluate for himself the evidence for many of the statements made. each chapter ends with some recommended further reading, but the text does not direct the reader specifically to the appropriate sources for the different assertions. This would indeed hardly be possible in a book with so wide a compass in such modest size.

Apart from general descriptions of the nature and properties of biological rhythms, circadian, lunar and annual, the author describes in more detail rhythms in unicellular and multicellular plants and animals, and the use of circadian clocks in animal, particularly in bird navigation, as well as some of the implications for man The popular appeal is contributed in part by anecdotes of the background of some experimental investigations, but also by such journalistic epithets as "flamboyant" experiments and the "callous" decapitation of cockroaches There is a similarly journalistic passage about the motivation behind human subjects for experiments, which in no way enhances the scientific value.

Little over half the book is written, however, by the author himself. It ends with two extended chapters, by F A Brown and by L N Edmunds, discussing the two rival theories that biological rhythms depend essentially on subtle geophysical rhythms, or that they are due to an internal timing mechanism. Dr Brown's constant advocacy of the former hypothesis is familiar enough, but his chapter is the least readable in the book A little of it is simply polemical, but the greater part consists of closely reasoned arguments demanding from the reader a highly critical attention More than one interpretation can be put on many of the experiments described, but it is convincingly shown that a wide range of organisms can respond to a variety of quite small geophysical influences whose detection was hitherto totally unfamiliar to animal physiologists

Dr Edmunds in the concluding chapter avoids a polemical adherence to the endogenous theory but considers various possibilities of its mode of operation. Simple and convincing evidence is given that, at least in some insects, the rhythmicity is controlled by a part of the central nervous system operating by the release of a chemical substance, and, that in mammals and birds the suprachiasmatic nucleus, operating by way of the pineal, plays a dominant or at least an important role. With regard to the fundamental question of the underlying circadian escapement, which has been shown to be present even in single enucleated cells, the three major theories are outlined. theories depending on a biochemical feedback loop, on transcription along a DNA template, and on ions and ion transport in membranes With the advantage of a limited field to cover, this chapter is perhaps the most successful in introducing biologists from outside this field to the major lines of thought, although in other respects, by virtue of the very broad coverage of different periodicities in such a wide range of organisms, the earlier chapters should be very helpful for those who want, as the author puts it, to get a "feel" for the subject **J. N. Mills**

J N Mills is Brackenbury Professor of Physiology at the University of Manchester, UK

Animal response to environmental parameters

Comparative Physiology of Animals: An Environmental Approach By Richard W Hill. Pp xii+656. (Harper and Row New York and London, 1976.) £9 90.

AFTER years with no suitable text for an undergraduate course in animal physiology, we are now confronted with a succession of such texts and the problem of choice This latest offering, by Richard W. Hill, is a very readable book intended for students beginning their study of the subject. Hill places his emphasis on the animal in its natural environment and on the physiological responses to the various environmental parameters rather than on the fundamental mechanisms underlying these responses The physiological principles and relationships are presented accurately but primarily in nonquantitative and descriptive terms, and the book should appeal to readers who favour this approach

The scope is ambitious since it embraces all animal groups aside from protozoans and metazoan parasites The chapter by chapter organisation is based on physiological functions or environmental factors. The opening two chapters on organisms in the environment and on energy metabolism set the stage nicely for the following chapters on thermal relations, salt and water exchange, excretion, gas exchange and circulation The book concludes with a series of integrative chapters on oxygen deficiency, high altitude, diving, exercise and rhythmicity These final chapters are particularly successful in tying together the earlier material while reinforcing the environmental theme of the book The coverage of the various topics is comprehensive although occasionally somewhat repetitive (for example, the section of salt and water exchange). But students will appreciate the careful exposition of the concepts and the extensive use of appropriate experimental data illustrating the concepts The more inquisitive students, however, may be frustrated by the fact that practically none of these experiments are referenced and most are not identified with the names of the investigators involved. Potential subscribers are therefore forewarned to put their own knowledge of the literature in order before assigning this text to their students. Some readers may also be troubled by the absence of any detailed discussion of the neural and endocrine systems, and the consequent patchy and superficial treatment of the role these systems play in the physiological response to the environment In spite of these omissions, I found the overall organisation and content of the book to be quite coherent. It is an excellent text particularly suited for courses attempting to bridge the gap between physiology and ecology

This book is not without value for more advanced readers as well Hill's emphasis on the animal's response to its natural situation should remind those of us who study 'non-laboratory' animals in the laboratory to design our experiments carefully with the objective being to learn how these animals function in their natural milieu Conversely, we must learn all we can of our particular animal's normal milieu in order to design useful experiments These are also important lessons for students just beginning their studies in the field, and this book should serve that purpose well, while at the same time providing a sound introduction to animal physiology **Donald C. Jackson**

Donald Jackson is Associate Professor of Medical Science at Brown University Providence, Rhode Island.

Human information processing

Memory and Attention: An Introduction to Human Information Processing. (Series in Psychology.) Second edition. By D. A. Norman. Pp. xiii+262 (Wiley: London and New York, 1976.) Clothbound £8.45, $15.45; paperback £3.95; $7.20.

Donald Norman's set of seminars on *Memory and Attention* have been useful to university teachers since they were first published in 1969. It is a pleasure to have a second edition, so adapted and extended that it is now virtually a new book. It is arguably also a different kind of book, since it is now probably the best and most cheerful introductory text one could recommend to a layman who wishes to understand how work on artificial intelligence and information processing is currently applied to psychological problems.

Among a large, mostly very recent, literature this book has distinctive virtues. First it is by a single author, who writes well. Second, it is short. Most importantly it is a good natured book, which seeks to be eclectic in appreciating the values of a wide range of different approaches. It retains enthusiasm without losing balance. It is a book to teach *with*, although possibly not a book to teach *from*.

Norman hopes that "the study of human information processing is becoming the study of the human" but aptly warns that "one must always be wary of comparisons of human psychology with any man-made device, most especially with computers. The human mind is not a computer, and the differences between the two far outweigh the similarities". Norman is also rare among workers in Artificial Intelligence in having a scholarly interest in the history of psychological problems. To quote one of his favourite authors, William James, he also has an appetite for the "more nutritious objects of attention" in psychology.

He is willing to accept the kinds of questions which students bring to psychology from their discursive reading, and while pointing out that some of them are unprofitable, is willing to discuss them seriously and in an illuminating way. Thus we find comment (and very useful references) on the topics of mystical experiences (Carlos Castenada *et al*), hemisphere differences (Ornstein *et al.*), mnemonic systems (an entire very useful chapter and excellent bibliography), pathologies of attention and of cognitive processes, and even the art of juggling. To some extent these are embroidery on a serious text, and they do not occupy much space. But they are not mere decoration. They provoke useful commentary, and show a recognition that the enthusiasms which bring students to psychology need not be stifled, but can mature into more usefully directed intellectual curiosity.

It is easy to dismiss such topics as irrelevant to current empirical work, and to depress students by insisting that psychology has nothing to do with the study of human experience and is concerned instead with the description of "performance" or "behaviour". Norman's caveat for psychologists should be taken seriously by all students, and properly understood is an antidote to the depression felt by research workers who may feel that they are wasting time on the precise definition of trivial problems. He points out that human beings have been the object of their own attention for a very long time, and that perhaps "We cannot discover anything surprising . . . It would be peculiar if our careful study of thought processes led to results which are at odds with our intuition". But he further points out that the bridging of a gap between a nebulous appreciation of generalities and the precision of predictive mathematical theory is an exciting, and ultimately a satisfying, occupation for a scientist.

The work follows the format of the first edition in presenting related readings with commentary and further development. The chapter on attention is now extended by a discussion of recent work by Kahneman and Moray, with useful remarks on the problems in terms of Bobrow and Norman's own distinction between "data-limited" and "resource-limited" processing. The previous section on short-term memory has been extended to cover the Craik–Lockhead idea of levels of processing. There are excellent chapters on pattern recognition programs sensibly restricted to detailed analysis of the problems encountered with a *single* new system (Reddy and Newell's Speech Understanding system). A section on semantic networks forms part of an excellent chapter on representational systems. There is a good introduction to imagery, in the same vein.

The book is research oriented rather than didactic, and ends as it should with a set of problems outstanding (Unfinished Business). Not the least of its values to students and to lecturers is the care with which really comprehensive bibliographies are assembled and annotated.

Patrick Rabbit

Patrick Rabbit is Lecturer in Psychology at the University of Oxford, UK.

Memories are made of this

The Psychology of Memory. (Basic Topics In Cognition Series) By Alan Baddeley Pp. xvii+430. (Harper and Row: London and New York, 1976.) Hardback £10.45; paperback £5.45.

AT LAST, a textbook on memory which one can recommend on its own, without three or four other volumes. The topic is a big one, ranging from the strange phenomena of clinical repression or 'photographic memory' at one end, to the effects of disrupting protein synthesis at the other. In the middle, there are groups of experimenters measuring the accuracy of memory in prescribed conditions, who are steadily building up the rules by which the system functions, whatever its physiological base. Even these groups are subdivided, some looking at associations between single items; some at memory for sentences and propositions, some at the similarities and differences of long-term and short-term retention; some at the importance of the particular form in which an event is encoded (roughly, perceived) at the time it occurred; and so on.

The difficulty is that each of these areas is still relatively unconnected with the others. All of them are advancing rapidly, it is hard enough to form a clear picture of the sense emerging from the mass of experiments in one field, without venturing into the others Most books therefore concentrate on one sector, often doing it well Yet the problem for the student or non-psychologist is that the picture he gets from such a book is one-sided. Even the slighter and more introductory texts often confine themselves to one approach, but merely replace detailed evidence by bald assertion. It is not surprising that even professional psychologists are sometimes unable to see the wood of progress for the trees of particular experiments.

Dr Baddeley's book, however, is different. It is not merely that his index mentions Freud as well as Ebbinghaus, Bartlett as well as Chomsky, acetylcholine as well as mnemonics. He could scarcely cover them all exhaustively; but the novel feature is that each field is mentioned appreciatively His own most familiar area is perhaps that of long-term as against short-term memory, but he is sympathetic to all, and though the amount of space he gives to each may get less as it becomes more remote from his own specialised expertise, the reader is left aware of every approach. Furthermore, the writing is beautifully lucid, and yet each point is based always on a well-selected experiment rather than generalities He is also accurate, which cannot be taken for granted.

Such a book should appeal to anybody who is prepared to read nearly four hundred pages on memory; despite the clear and attractive style, it is all information rather than exhortation. Readers will therefore need to come to the book already convinced the subject is important. If, for example, they are doing an honours degree in psychology, or worried by the memory failures they meet in neurological practice, they cannot do better than pick on this book as their main source of information.

As favourable a review as this one is, some criticisms are still necessary as a guarantee of a proper standard. First, the sequence of topics is rather arbitrary, and one feels the chapters could be read in almost any order. This seems to stem from boredom with the conventional approach of starting with the arrival of a stimulus at the senses, and following it through. Perhaps this convention has some merit in the absence of any other organising principle

Next, the distinction of short-term and long-term memory is surprisingly cavalier, and relies heavily on the very rapid forgetting of recent as opposed to more remote events But this phenomenon, as has often been said, does not justify such a distinction. Dr Baddeley is now used to distinguishing far more than two kinds of memory, but some students will still be struggling with their tendency to parsimony, and could do with a clearer presentation of the reasons for abandoning a single homogeneous memory store

Finally, the excellence of the book for teaching means that Dr Baddeley's own ideas have not been let loose. We could do with expansion of his brief suggestions about a modified interference theory, or about the role of talking to oneself for working memory during mental arithmetic. Perhaps a specialist monograph might follow? Yet this survey is itself a contribution to the subject since it reminds us all that research in this field has come a long way in twenty years.

Donald E. Broadbent

Donald Broadbent was Director of MRC Applied Psychology Unit from 1958–74, and is now on the MRC External Staff at the Department of Experimental Psychology, University of Oxford, UK.

Now available, thoroughly rewritten and up-dated:

INORGANIC CHEMISTRY

A Guide to Advanced Study

A completely revised successor to Heslop/Robinson, Inorganic Chemistry

by R. B HESLOP, *Senior Lecturer in Chemistry and* K JONES, *Lecturer in Chemistry, The University of Manchester Institute of Science and Technology*

The original Inorganic Chemistry, by Heslop/Robinson, achieved longstanding, worldwide popularity as a text-book of moderate size covering courses to degree level The present work will undoubtedly repeat that success. A full survey of the chemistry of the elements is presented by treatment of the groups in the Periodic Table.

Important new features include: extra attention to the physical methods used for the determination of structure and the understanding of chemical bonding; introduction of ideas on molecular and orbital symmetry which are utilized throughout the text; the exclusive use of SI units; practical examples and useful exercises with answers.

A concise, readable and clearly-organised text for students, it will also serve as an up-to-date reference book for teachers.

COMMENTS

"Strikes a good balance between theory and descriptive chemistry Descriptive chemistry is very well organized "
Robert H Lane, Univ of Georgia

"I like it, especially the early chapters and the extensive use of redox diagrams summarizing much information quickly and readably "
Donald H. Williams, Hope College, Holland, Mich

Substance of demography

A GROWING interest in our species is reflected in the recent appearance of several general textbooks on demography. *Population: Analysis and Models* by L. Henry (Arnold: London, hardback £9.95; paperback £4.95) adds a valuable member to the company and demonstrates the continuing strength and vitality of the French contribution to these studies. Although in agreement with the translators that no demographer can be without a reading knowledge of French, they are to be congratulated on providing an excellent translation for those whose command of the language is imperfect. This is nevertheless an imposingly technical text, with considerable mathematics, although for the less numerate progress is eased by the usually clear and adequately explained steps. The text introduces a useful and interesting graphical tool, the Lexis diagram; elsewhere, however, more might have been explained by graphical presentation: the treatment, for example, of age–sex pyramids seems to be unnecessarily brief.

M. Henry's approach follows in general the now common 'longitudinal' study (developed by American and British demographers), the examination of data based on generations rather than the more limiting and older 'cross-sectional' method using only data from periods of a few years. The longitudinal approach is useful in enabling the link between population structure and movement to be clearly developed, and is well suited to the sociological emphasis of demography in the English-speaking world.

The description of the book on the jacket stresses that it covers the conventional substance of demography—source materials, methods of description, nuptiality, fertility, family formation and mortality (note the order!)—but also emphasises the author's attention to migration and its effective integration with population structure. Amid all these goodies, however, one dish seems inadequately prepared. There seems to be a general weakness among demographers that they give little depth to the spatial elements of population—on p 13, under "Analysis of the Results", two meagre paragraphs on geographical distribution are so trite that they would have been better omitted. But even later in the text, especially when dealing with migration, the spatial element of which is so pronounced, there are statements over which geographers would readily take issue with the author. Regional variation in dynamic patterns seems to go inadequately recognised.

Part II, the final but lesser half of the book, is an introduction to demographic models and, perhaps importantly, a statement as to why models are of value and why they should be considered by demographers. Much of this section is centred round Lotka's theory.

The French version of the UN multilingual demographic dictionary adds a final phrase to the definition of demography that it is a study "from the quantitative point of view"—M. Henry has made just this point.

Methods and Materials of Demography by Shryock *et al.* (Academic: New York and London, $16.50; £9.55) is a condensed version of a two-volume work of the same title originally published by the US Bureau of the Census in 1971 with subsequent later editions. It is now designed primarily as a textbook for courses on various aspects of demography, but it is equally useful to professional workers with occasion to understand or use demographic data for analytic studies

The author of the abridgement claims to have presented the methodological material in the simplest mathematical form in order to make the text as useful as possible, a claim which even cursory examination of the text supports. For the most part a modest understanding of algebra and statistics will suffice to carry the user through the relevant sections.

Although originally a publication of the US Bureau of the Census, the illustrations and coverage are not solely restricted to American examples, but considerable weight is given to the problems of demographic assessment in the less developed countries. The author does, however, stress that the methods and measurements worked out for the USA are to a considerable degree "culture free" and may serve as well for any other country. In this condensation a necessary choice of inclusions and omissions had to be made, but a balance between formal demography and social and economic demography was sought. In this search, the author has been reasonably successful.

In general the step-by-step illustrations of examples are based on actual figures, although necessarily hypothetical statistics have had to be used in some instances. Where official statistics have been used they have mainly been taken in their form as published, apart from a few instances of simplification. In this condensation, less emphasis has been put on historical development, the recommendations of international organisations and the practices of national statistical agencies, whereas the more technical and mathematical aspects of demographic analysis have been reduced in emphasis.

The book is, however, not without its weaknesses. Certainly chapter 5—Population distribution Geographic areas—leaves many gaps, especially in the discussion of the important aspect of mapping distribution. The range of techniques examined is quite inadequate, and unfortunately some of the less impressive and informative methods are chosen for black-and-white line diagrams.

Nevertheless this is a fact-packed text invaluable to the do-it-yourself census maker, and brings together much material otherwise diffusely scattered. For any serious course on the principles of demography it should prove a useful if expensive textbook.

Comprehensive geomorphology

Analysis of Landforms by C R. Twidale (Wiley Australasia: Sydney, New York, London and Toronto, £13.50; $27) is intended for use as a text at advanced school level and for those taking degree courses in geography, geology, Earth sciences and environmental sciences. It sets out to provide a general text with an emphasis on Australia but with an adequate coverage of world examples.

The method of presentation leans heavily on photographs and diagrams and the book is lavishly illustrated. Yet its size is such that the written discussion is ample, as well as being of high quality and backed by discreet quantification. To keep the volume within manageable length, the nature and methods of close analysis are illustrated from a relatively few selected landforms, such as flared slopes, but here again the spacious text allows the general field to be covered in considerable detail.

The voluce opens with a discussion of the scope, problems and methods of landform analysis and reveals a preference for multiple working hypotheses. The second part deals with structural geomorphology, including pseudo-structural forms; the third with geomorphological processes and climatic geomorphology; and the fourth with changes in time or historical geomorphology. The concluding part summarises the number and variability of factors involved in landform creation.

So it is better to travel hopefully than to arrive, but the student with this attractive companion will enjoy and benefit from the journey, especially as its ample text is strengthened by plenty of references and an enlightening geological appendix. The cost may seem high to those who have not seen the volume, but in fact its lavish visual aids and large-format pages make it good value The printing—carried out in Singapore—is handsome and effective and adverse criticism must be minimal. It is misleading, however, to use Mercator's cylindrical projection for global distributions such as plate tectonics. This graticule has no uses whatsoever except for finding compass directions between localities, and students will never truly understand global distributions and movements until they see them on equal area projections.

Another recent book, *Geomorphology from the Earth* (Harper and Row: New York and London, £14.20), is a compact synthesis of geomorphology and stems from Chicago, an early citadel of landform studies. Its author is well known for his illuminating writings on the physical environment and its significance for Earth sciences ranging in diversity from archaeology to biology. He assumes—quite rightly—that an understanding of the surface forms and textures of our planet is a necessary ingredient of a liberal education, that landforms and the processes that create them are fascinating to scientists and curious people everywhere; and that persons of all ages and educational backgrounds gain from geomorphology a new appreciation of other environmental sciences I have known students with souls so dead as to exclude empathy, males more curious about velocity than volcanicity, and females more interested in finery than feldspars, but have no intention of being an ancient mariner at a geomorphological feast for this is attractive fare laid out in an enticing way.

Professor Butzer keeps his aim of a general introductory text clearly in view and includes the essentials, critical interactions and brief overall perspectives New findings and modern developments are incorporated throughout with a judicious use of mathematical expressions and, for readers who want more specialised aspects, with ample international sources in lists of references The contents cover a broad field and, being confined to a moderate length, vary in intimacy of detail, the tendency being to elaborate most on forms and processes of greatest human significance. Commendably, space is found for a historical summary of modern concepts, before dealing with the lithosphere, weathering, soils and the sculpture of hillslopes There follow discussions on topics such as fluvial dynamics and erosion, the work of glaciers and of waves and the importance of crustal movements. Separate chapters are devoted to periglacial landforms and to the characteristic landscape assemblages of mid-latitudes, deserts and tropical regions.

The high quality of the explanations, diagrams and photographs and the emphasis on the essential rather than the exotic will be admired by geomorphologists. Perhaps general readers may not appreciate the wisdom in the compilation but they will realise that geomorphology is a fascinating science and of great human significance The text, in spite of its price, will also be valued as a stimulating revision for students already acquainted with the subject.

Perspectives on physical geology

PHYSICAL GEOLOGY, defined by S. Judson *et al.* in *Physical Geology* (Prentice-Hall. Englewood Cliffs, New Jersey, $14.50) as a discipline which "addresses itself to the composition, classification and origin of earth materials, and to the physical and chemical processes which go on at or beneath the earth's surface", covers a formidable range of material. At the small scale it deals with soil creep and at the other global tectonics. In addition it seems that under its umbrella one must attempt to cope with the study of resources, with environment, and with the characteristics of other planets.

It would be remarkable, given the scope that this offers, if three books on physical geology were to cover the same material in broadly the same way. Three recently published volumes however, are remarkable in just such a way. They have plainly been aimed at the same market (majors and non-majors in a one-semester or one-term course at the American college level), they have broadly similar format (multi-colour printing, many illustrations, good type); they all attempt to cover similar ground, and they all make commendable efforts to be comprehensible and attractive.

The differences between them are of a cosmetic rather than a fundamental nature. J H. Zumberge and C. A Nelson in *Elements of Physical Geology* (Wiley. New York and London, £7.20; $14.40) offer the best colour illustrations of rock types and minerals together with an illustration of a seemingly topless Hawaiian surfer J E Sanders *et al* in *Physical Geology* (Harpers College, Harper and Row London and New York, £10.45) offer flip drawings of Pangaea on the top corners of some 40 pages to "present the idea of drifting continents as vividly as possible", together with extracts from other writers (which they term "field trips"). And Judson *et al.* both pose and answer questions for the student, but (presumably why on a page for page basis they are cheapest) they offer slightly less glitter.

A second remarkable feature of such books would be for them to range successfully and adequately across the great range of material they seek to cover. Broadly speaking all of them do this, and broadly speaking their content and their guides to further reading are up-to-date They all seek to put across the rudiments of mineral characteristics, rock types, volcanoes, weathering, mass movement processes, rivers, orogeny and plate tectonics Judson *et al.* use the plate tectonics concept as a framework for much of their discussion whereas it is less prominent in Zumberge and Nelson and in Sanders *et al.*

Inevitably there are inadequacies, omissions or lack of awareness of recent work. Rates of geomorphic processes are consistently neglected; climatic changes are given scant attention; coral reefs are accorded little prominence; Davis's great cycle of erosion is relegated to the very briefest of mentions, and the nature of water movement in drainage basins (particularly throughflow and runoff generation) is hopelessly out-of-date in the way that it is treated.

Overall there is not a great deal to choose between these three texts. They all offer clear, well-produced introductions to their views of physical geology. Probably their main use in Britain will be as texts for sixth-formers, but most University undergraduates would find shorter texts covering specialised topics at a greater depth more useful.

Andrew Goudie

Andrew Goudie is Lecturer in the School of Geography at the University of Oxford, UK.

Structural geology

An Outline of Structural Geology by B. R. Hobbs, W. D. Means and P. F. Williams (Wiley New York and London, $20; £10) is intended to replace Sherbon Hills' *Outlines* (Prentice-Hall, 1972) as a comprehensive text on structural geology for undergraduates. The involvement of three authors, all well known and experienced research workers, is perhaps a comment on the rapid growth in the complexity and diversity of the subject over recent years. Some years ago structural geologists were chided with scientific myopia, specifially, for having 'played' with minutiae while others discovered plate tectonics. Fair comment or not, this reminds us that when subjects develop toward a labyrinth of narrow specialisations there is an urgent need for a survey of the whole field of activity.

The plan of this book is not novel, indeed it has much the same lay-out as Sherbon Hills' and its success depends on the quality of treatment of familiar topics. It starts with mechanical aspects and stress–strain theory, and progresses from minor structures (microfabrics) through folds, faults, foliation and lineation to major structures and, finally, plate tectonics. The 'bridge' from small to large is in parts of a useful, but rather brief, chapter on "structural associations", that is thrust belts, block faulted regions, and so on. There is also an essential chapter on geometrical analysis and this topic, including stereographic analysis, is continued in an appendix.

It is a pleasure to record that the authors' surefooted approach, with its mingling of fact and comment, hardly ever lets them down. Fortunately, the authority which is evident in individual sections of the book is not spoilt by any overall lack of balance which is I suppose a danger when several authors are involved. Of course it is not perfect. For this reader, the splendid section on microfabrics is not always matched elsewhere in the book and it is surprising to find so little on fluid pressures, or on pressure solution, or on techniques for estimating strain, shortening and displacement in orogens. My impression is that the authors are happier on the minor structures than with major structural phenomena. Their chapter on plate tectonics, however, is quite admirable.

The illustrations are vital in a book on structural geology and here there are many excellent diagrams and photographs, and very few disappointments.

The authors have designed their book for undergraduates. There are several potential rivals even if we exclude J. G. Ramsay's classic advanced book (*Folding and Fracturing of Rocks*, McGraw-Hill, 1967) and that by F. J. Turner and L. E. Weiss (*Structural Analysis of Metamorphic Tectonites*, McGraw-Hill, 1963), which has never been suitable at this level. The most recent editions of the respected books by L. U. de Sitter (*Structural Geology*, McGraw-Hill, 1964) and M. P. Billings (*Structural Geology*, Prentice-Hall, 1972) cannot be considered as truly modern in approach.

The books by E. W. Spencer (*Introduction to the Structure of the Earth*, McGraw-Hill, 1969) and P. C. Badgley (*Structural and Tectonic Principles*, Harper and Row, 1965) share some of the virtues of de Sitter's book in that they include 'potted' accounts of classic regions for the study of deformed rocks and this must be an asset for the hard pressed undergraduate. But the present book must surely take precedence over these because it goes further toward the goal of presenting structural geology, not only in modern terms but also as a coherent subject based on physicochemical laws I think the research worker will also benefit from this reliable and well produced book **M. R. W. Johnson**

Carter and the test of energy

For the first time since the Arab oil embargo, the United States Government seems ready to consider adopting a comprehensive energy policy, one which involves efforts to curb the nation's profligate consumption as well as attempts to step up domestic energy supplies. Such a policy is long overdue, but it will severely test the will and the political skills of the new Carter Administration to put it into practice.

Although both Mr Nixon and Mr Ford paid a good deal of lip service to the need for energy conservation during their terms in office, their energy policies consisted essentially of throwing large sums of money into the supply side of the energy equation. Indeed, when Mr Nixon launched his infamous Project Independence, he even insisted on making absurd claims that American technology would free the United States from relying on imported oil to meet its energy needs by 1980. The demand side of the equation was badly neglected, perhaps for understandable reasons.

The United States has grown up with cheap power, with the ethic that bigger means better, and with the philosophy that the government has little right to meddle in the workings of the so-called free market. All that would have to be changed if a serious attempt is made to curtail energy demand. Mr Nixon, who was already under siege when the oil embargo struck, probably lacked the political ability to pursue effective conservation policies—in any case, he didn't make much of an effort. And Mr Ford suffered the handicaps of being an unelected President who belonged to a different political party from the one which controlled the Congress and who had an abiding faith in the free market.

President Carter may be different. His campaign rhetoric was peppered with promises to develop an energy policy, and he has repeatedly warned that it will require considerable 'sacrifice' from the American people. He also comes to office riding a tide of goodwill and—perhaps most important—this year's extraordinary winter has provided a more vivid argument for conservation than a thousand Presidential statements. If Carter doesn't manage to put an energy policy into effect, it would be a serious indictment of his Administration's political ability.

So far, Carter's efforts are promising. The first major instalment of his energy policy came last week when he proposed legislation to consolidate most of the federal government's sprawling energy bureaucracies into one Cabinet-level department under the direction of James Schlesinger, former head of the Atomic Energy Commission, the Central Intelligence Agency and the Department of Defense. Though the proposed arrangement is eminently sensible, the bill would clump together agencies and programmes which are now handled by different Congressional committees. Some jurisdictional disputes may therefore delay passage of the Bill, but approval is nevertheless anticipated.

Once in place, the Department of Energy should be in a better position to plan both conservation and supply policies. That's where the second instalment of Carter's energy policy comes in. He has promised to unveil a comprehensive energy plan on 20 April, with particular emphasis on conservation. A preview of at least some of the elements of that policy was provided last month when Carter sent Congress a number of revisions to the budget proposals which Mr Ford left behind.

As far as research and development are concerned, Carter's policy will concentrate on efforts likely to produce results in the relatively near term. Thus, long term efforts such as the breeder reactor programme, nuclear fusion efforts, and the development of large scale solar power plants, would be cut back and the money reprogrammed into energy conservation and into efforts to get already-developed technologies, such as solar heaters, into the market-place. The justification for such moves is that it will probably be more difficult to commercialise new energy technologies than to develop them, and government incentives are required to feed the growth of, say, a solar energy industry. Those arguments are likely to find favour in Congress.

As for curtailing energy use, the Administration can pursue only a limited number of technological fixes, such as forcing the automobile industry to make more efficient cars and encouraging the use of battery-driven vehicles. But the most effective energy conservation measure would be to increase energy prices through the use of federal energy prices through the use of federal energy taxes.

Such a move would, however, be very difficult to get through the Congress and it would also have to be coupled with a system for returning the tax revenues back into the economy, preferably in a manner which would mitigate the burden on low income groups. It is estimated that every cent of tax on a gallon of gasoline would raise about $1,000 million in revenue; a large tax could have a depressing effect on the economy. One idea which is being floated is to return some of the tax revenues into energy-saving measures such as income tax credits for home insulation, construction of mass transit systems and so on. In any case, the Carter Administration has already begun to leak the fact that it is considering raising energy prices in order to prepare the American public for the inevitability of a long overdue move away from the present artificially low prices of energy. □

Between the devil and the deep blue sea

Robert W. Cahn, Dean of the School of Applied Sciences at the University of Sussex, offers this comment on the prospect for fusion power

In the anguished debates on the future, if any, of nuclear fission power, various recognisable strands emerge among the opposition. Some pin their faith on the improved technological exploitation of familiar fossil sources, principally coal; others would drive us headlong into the solar economy, often conceived in terms of 'small is beautiful' and a rural life of log-cabin simplicity; yet others accept the need for high technology on a very large scale if the sun is to yield domestic warmth, electricity and liquid fuel on an adequate scale.

All three groups, however, have one characteristic in common. When faced by hard statistical or technological criticisms, they declare that we need only keep going for a few decades and then the boundless energy "from seawater"—that is, nuclear fusion—will become a reality and all our worries will be over. Although they do clearly recognise that the method is not altogether simple, even the most resolute proclaimers of radioactive doom seem to have convinced themselves that fusion power will be gentle and on a homely scale, and that radioactive pollution will be a thing of the past when dirty fission gives way to clean fusion. Probably the fact that fusion takes place in the sun and that the sun is the emblem of cleanliness and of life itself, has something to do with this touching faith. We are all to some degree subject to the ad-man's technique of fallacious association.

There is no dearth of popularisations of this very difficult and complex topic, but they all concentrate on two aspects of fusion—how to confine the plasma, and how to heat it to ignition temperature. Even within these limits, they tend to concentrate on scientific principles and not on engineering realities, whereas the current critcism of nuclear fission concentrates on real and alleged engineering weaknesses. Nuclear fusion has progressed far enough now towards the design of a self-sustaining reactor to make it both possible and necessary to see the problems in realistic terms. The plasma confiners—which indeed have a ferociously difficult task—until recently have hogged all the attention, to the neglect of the problems of energy balance (achieving a positive net energy output), container strength and fatigue damage, lithium supply, reactor cooling, injection of gas into the plasma without quenching it, and especially the radiation damage inside the reactor itself.

That this imbalance is now being repaired is primarily due to the efforts of the Energy Research and Development Administration (ERDA), which has complete control of fusion research in the United States. ERDA has prepared a detailed R&D plan extending to 1990, and in outline to the end of the century. ERDA's achievement is to have set out this programme without committing itself to any particular design of reactor, and yet to have identified the central problems which will have to be faced irrespective of the design. To do this, ERDA's predecessor in 1967 invented the concept of the 'reference design'. This is an outline based on scientific principles, as presently understood, set out in such a way as to identify, as quantitatively as possible, the whole range of engineering problems that will need to be mastered. Such a reference design is particularly illuminating when applied to the doughnut-shaped Tokamak, which in purely scientific terms is today probably the most hopeful contender among the rival approaches.

On the basis of such a reference design, the problem of securing the deuterium (by electrolysis of water?) and tritium from a metre-thick breeding blanket of molten lithium surrounding the first wall of a doughnut-shaped plasma device, can be analysed, not least in terms of lithium availability; lithium is a scarce element. One day it will also be necessary to include in the energy balance equation not only the energy cost of extracting tritium from irradiated lithium but also the electricity costs of electrolysing water to extract deuterium, a calculation which never seems to be reported.

Probably the most alarming engineering problem is that of radiation damage. In the much-criticised fission reactor, neutrons, gamma rays and fission particles remain inside the reactor volume, and indeed the fission products remain inside the nuclear fuel itself. In a Tokamak, all the neutrons, moving with a kinetic energy of some 14 MeV, beat upon the first wall: the scale of this bombardment dwarfs anything in a fission reactor. The wall can be sputtered away, especially by the novel hazard of 'chunky sputtering' which involves the physical removal of thousands of atoms at a time.

A great deal of research is now in progress on this group of problems in the United States (some also in Britain), and considerable advances have been made in improving the radiation resistance of high-strength refractory alloys. But it is certainly an error to regard fusion reactors as generating little radioactivity: there will be a great deal of induced radioactivity, though not from fission products, and it will be just as crucial as in the case of a fission reactor to contain and seal off this radioactivity from the outer world. (It seems likely that this hazard will not be long-lived). Apart from this, there will be just the same hazards of pinholes developing in inaccessible locations as have been found with prototype fission-breeder reactors, leading to deterioration in cooling efficiency or vacuum quality.

Fusion may prove to be a practical source of energy—the new issue is now as much in the hands of the engineers and metallurgists as of the plasma physicists. If it comes, it will be an immeasurable boon but it will also bring with it problems of pollution, energy imbalance during construction, resource depletion, sabotage and potential stoppage such as we find with every other source of energy, including solar techniques such as the large-scale fermentation of timber to make liquid fuel.

For Blake, energy was a mark of the divine. Milton knew better: Satan has energy too. Whether the external flames are fed by coal, oil, uranium or deuterium is a question which must tax the physical theologians of the future. ☐

Fusion technology: installing coils on a torus in Germany

Europe's nuclear debate (1)

Austria: a case study

Helmut Hirsch and **Helga Nowotny** assess Austria's nuclear energy information campaign

NUCLEAR energy has become a topic of interest in Austria much later than in other countries, so her politicians and scientists have been able to study the development of the issue for some time. It has also come at a time of social stability, when even a small disturbance would not go unnoticed. This, and the manner in which the authorities control and institutionalise conflicts, help to make Austria an interesting case-study. For unlike the experience of other western countries, Austria's nationwide nuclear debate was initiated by the government. It organised the *Informationskampagne Kernenergie* (nuclear energy information campaign), and from being a topic important only to a few environmentalists and dwellers near proposed reactor sites, the subject became a national concern drawing more and more citizens into action groups.

The first steps were taken in July 1975. The Federal Chancellor's Office was responsible for the organisation, and a committee of civil servants, chaired by the head of the Energy Section of the Ministry for Trade, Commerce and Industry, Dr W. Frank, took over the scientific preparation. An exhaustive catalogue of questions was compiled, divided into well-defined subtopics embracing economy, safety, environmental and biomedical questions. In accordance with frequent practice and to avoid suspicions of manipulation, the cooperation of nuclear energy critics was sought, among them the Austrian Nobel-prize winner Professor Konrad Lorenz, and Doz. B. Lötsch, the head of the Viennese Ludwig Boltzmann-Institute for Environmental Sciences.

Each of the subtopics was to be dealt with by a group of experts, consisting of critics and promoters of nuclear energy in equal numbers (about three of each). This pro–con classification later proved to be an over-simplification: many scientists don't fit into either category, many more belong clearly to one side but refuse to admit it. Preliminary discussions would clarify as many points as possible, while the open problems would be left for the public debates. Finally, a report was to be produced containing relevant information, answers to questions on which consensus was reached and recommendations for further research. Although the organisers believed scientific controversies arose simply because there was not enough data (unless they concerned an issue that wasn't a real scientific problem), this later proved a rather naive conception as controversies also exist about which data can be regarded as relevant and about the appropriate framework for their interpretation.

Emphasis on independence

Strong emphasis was placed on the independence of the experts. People employed by electrical utilities, the nuclear industry, or concerned with the licensing of nuclear power plants participated only in internal debates as consultants. Civil servants were also excluded as experts from the various ministries because they would have to contribute in subsequent parliamentary debates. Thus, the government could remain non-committal, not being responsible for what independent experts choose to say or write. For the same reason, politicians from the governing Socialist Party participated little; their frequent absence from the debate was often criticised.

Promoters of nuclear energy felt that the campaign would emphasise the disagreement between experts and only increase public fear and suspicion. But most critics failed to appreciate the genuine attempt to avoid the errors made in other European countries. Hence the emphasis on sub-groups working on different topics—too often discussions had remained superficial and disorganised; and the attempt to balance the expert groups between pro and con—too often 'information' had proved to be only state-sponsored propaganda.

The government took the final decision to initiate the campaign on 17 February 1976. As there were ten subtopics, ten moderators for the expert-groups, mostly university professors, were selected by Dr Frank. As every expert has a personal opinion or a professional bias on the subject, it was impossible to choose strictly neutral moderators. Nuclear physicists and economists specialising in energy problems tended to be pro-nuclear, whereas the rest were critical or at least suspicious. Most felt ill at ease in their positions.

The internal debates, organised and conducted by the moderators, started in June 1976. No questions were excluded from the public debate because it was impossible to define clearly solved and unsolved problems.

To prepare the public, the Federal Press Service issued a booklet providing basic information, *Nuclear Energy—A Problem of Our Time.* Although controversial issues were reserved for the subsequent debates, disagreement among the authors (mainly the moderators) was considerable and many passages were tentative and noncommittal. Nevertheless, both critics and promoters of nuclear energy voiced negative and positive opinions: one group of critics requested that all copies of the booklet be destroyed, while another wanted 2,000 copies for local distribution and complained about the small number printed (15,000).

Votava

Chancellor Kreisky: his office organised campaign

The experts and organisers, at least the pro-nuclear ones, imagined that the public would listen eagerly and trustingly to the specialists' lectures in spite of strong fears about nuclear energy. The majority of anti-nuclear experts saw the audience as a concerned population with legitimate claims. The possibility of changes in the concept of the campaign as a result of effective, well-organised public action was ignored by the organisers as impossible to incorporate within the chosen framework. This indicated little flexibility in the organisation and an unwillingness to accept active public participation.

The main features of public reaction to the campaign became evident during the first public discussion in Vienna on 14 October 1976. There was strong resentment at the idea of listening passively to a panel discussion and only being allowed to submit factual questions in written form; the public demanded open discussion and it soon became apparent that the rules would be impossible to enforce. Massive distrust was expressed in the campaign: there was some surprise in the first debate when it became apparent that three of the panel experts were nuclear energy critics as opposed to mere propagandists.

Lack of consideration for the political viewpoint was another source of provocation to the public: while general problems concerning nuclear power were being discussed, Austria's first plant was nearing completion. The decision to build had been taken long ago and the construction proceeded throughout the campaign. Pressure was exerted to stop the plant going into operation and a resolution was passed to this end. Finally, the concept of having separate topics for each evening, in different towns, was criticised; although the theme of the first, general social and economic problems, was sufficiently broad, some of the subsequent ones were of little interest to the public which was anxious to discuss the more crucial issues.

In spite of the criticisms expressed during the first debate, plans for the next discussion in Linz remained unaltered; it was to be even more strictly controlled from the platform. The reaction was especially vehement, as the topic of the evening, energy policy, did not seem relevant to the people living near the proposed site of the second nuclear power plant. In addition, no outspoken critic was among the panel. Consequently, with almost unanimous consent, about fifty organised critics took over the panel and continued the meeting with their own chairman.

To reduce dissatisfaction with the division into different topics, it was decided to reinforce the panels with 'consultants', mainly experts in the biological and medical fields, who could be called upon if necessary. The next four debates proceeded uneventfully, even when two of the panels, dealing with economic problems, showed a strong pro-nuclear bias. The public discussions became less rigidly controlled and organisers and chairmen held preparatory talks with local opposition groups before each meeting, giving the latter the right to read longer statements or resolutions if they respected the rules of the debate.

The precarious balance achieved by these conciliatory measures broke at the seventh debate, in Vienna, on 27 January 1977. The hall could not seat all the people who arrived but after massive pressure short of violence, everyone was finally allowed in. The first panel statement, made in a provokingly patronising way by a promoter of nuclear energy, was halted by interruptions and a recognised critic among the panelists elected a new chairman. Thereafter, the discussion concentrated on how to stop the construction of Austria's first nuclear power plant.

The following two meetings, held in small provincial towns, were less dominated by the critics; these were comparatively peaceful, although the main criticisms were upheld. The final debate in Vienna, due on 24 March, will probably be controlled entirely by the opponents of nuclear power.

Coverage of the campaign by the mass media has been poor, being limited to superficial accounts of the arguments presented by the experts or the more spectacular actions of the protesters. Opponents have developed the theory that the government is deliberately hindering publicity in order to avoid raising public concern. Although radio and television are not state-controlled, it is indeed debatable whether sufficient efforts have been made to ensure adequate coverage.

At present, plans for the second phase of the campaign are in progress. Representatives of opposition groups, electrical utilities, the nuclear industry, as well as employers' and employees' organisations, will be invited to four symposia. These, to be held in May and June 1977, will be devoted to a discussion of the reports compiled by the ten expert groups. The results, together with a summary provided by the government, will be submitted to parliament, to serve as background for a subsequent decision on nuclear energy, and then published.

From a preliminary evaluation, certain points emerge:

- The organisers exercised considerable control, through their choice of experts, on the political credibility of the debate. But they had no influence over public reaction.
- Considerable differences emerged between public and internal debates. While the latter usually took place in a friendly atmosphere in which disagreements were respected by colleagues, opponents and proponents were extremely conscious of their respective roles in the public debates.
- The public was highly distrustful of expert panels set up by the authorities. There were accusations that experts were being paid by the nuclear lobby and that the government was staging a mere puppet show with political decisions having already been taken behind closed doors.
- The public reaction manifested 'scientific populism' and resentment of establishment science. Dissenting scientists quickly became celebrated as heroes. Although opposition groups sometimes displayed a moving willingness to delve into scientific details, anything outside their pre-conceived notions was unacceptable to them. What they demanded was a 'people's science'—a body of knowledge controllable by them.
- Coverage by the mass media was mostly determined by factors unrelated to the information campaign. It tended to dismiss the protest movement as extremist or based on irrational fears; opposition newspapers automatically wrote in a negative way about the campaign. Only in Vorarlberg, where the population had been made aware by opposition to a planned Swiss reactor close to the border, did the local movement receive strong press support.
- The authorities had not considered the political context sufficiently: the public was expected to consist of 'neutral citizens' only, to whom information would be offered as a public service. This neutral citizen, however, either doesn't exist, or is not sufficiently interested to attend the meetings. ☐

Traditionally, a large percentage of Austria's electricity requirement has been met by hydropower. The growing energy demands of the country's economy, however, finally led it to consider the nuclear option. In 1971 construction of the first nuclear power station began near Zwentendorf in Lower Austria. It is being built by the West Germany company Kraftwerke Union, although Austrian firms supply know-how and a considerable number of components. The company owning it is half state-owned and half-owned by the utilities in the federal provinces. The station should be supplying electricity to the grid by March 1978.

Public concern grew when talk began of a greater commitment to nuclear energy. The construction of a 1,300 MW plant was originally scheduled to begin in 1976; another was planned for the early 1980s. In the spring of 1975, groups of concerned citizens in Upper Austria —near the proposed site of the second plant—collected over 60,000 signatures in a local petition against the plans.

With nuclear energy a much debated issue in other countries and producing violent confrontations, with the recession (felt only slightly in Austria) reducing the need for greater electricity generating capacity, and with an election planned for the autumn of 1975 creating additional pressure on the government, all decisions concerning future commitments to nuclear power were postponed. Work on the planning of the second and third plants was suspended; construction of only the first plant proceeded normally. Later the government declared that the alternative to nuclear power would be increased use of (mainly imported) fossil fuels or imported electricity. In February 1977, responding to questions submitted by the opposition in parliament, the government pointed out that this alternative was economically feasible, although parliament would have to decide whether it was desirable. This decision is expected at the end of 1977. Of the three parties represented in the Austrian parliament, the governing Socialist Party is divided over the issue, but has a pro-nuclear bias, and the People's Party is pro-nuclear but highly critical of the way the government handles the problem: the smallest, the Liberal Party, is decidely anti-nuclear.

In the summer of 1976, the nuclear energy critics founded a nationwide federation outside existing parties incorporating eight local groups in all but one of the federal provinces. The number has since increased to at least twelve.

Europe's nuclear debate (2)

Germany: growing acrimony

Werner Gries looks at the controversy over the use of nuclear power in West Germany

THE row in West Germany over the peaceful use of nuclear energy has grown increasingly fierce over the past few months. It reached its latest climax on 19 February with the siege of the nuclear power station at Brokdorf, where scores of people were detained by the police after a clash with militant demonstrators who tried to occupy the power station site. A similar demonstration last November, also at Brokdorf, was also violent. Meetings held all over the country to discuss the necessity for nuclear energy at all have produced clashes between supporters and opponents of nuclear power. The press, radio and television have busied themselves conducting detailed investigation into the pros and cons of the issue.

The result of all this activity, in some eyes at least, is little result at all. In spite of the wave of anti-nuclear demonstrations, a recent opinion poll indicates that a slight majority of the population is in favour of the construction of nuclear power stations. In an all-party resolution last year, the Bundestag (parliament) declared itself unanimously in favour of the continued use of nuclear energy so that West Germany's future energy supplies could be guaranteed; the Ministers President of the Länder (provinces of the federal republic) followed suit. Such agreement at government level, though, has not prevented various branches of the Social Democratic party calling for a halt to the building of nuclear stations; in some cases they have organised joint demonstrations with local people to protest against new plants. All political parties are involved in the debate, and each has in its ranks both supporters and opponents of nuclear power—the governing coalition of Social Democrats and Free Democrats displays more disagreement than the opposition Christian Democrats and Christian Socialists.

Federal complications

Additional complications have sprung from the country's federal framework. Individual Länder, for example, are responsible for authorising nuclear power stations in their own areas. Several local courts have granted injunctions to stop the building of new plants because of protests by private citizens. In Schleswig-Holstein, a court ruled that work on the Brokdorf nuclear power station could not start until a way of disposing of the waste had been agreed on, and in mid-February a court in Rhineland-Palatinate banned further work on the Müllheim-Karlich station near Coblenz because of technical errors in the construction. The government of North Rhine-Westphalia has banned the building of all new power stations within its area until a method of waste disposal is agreed. Some sites have been brought to a standstill, others have experienced partial stoppages; at some sites it has not even been possible to begin the construction work.

One of the major obstacles to have arisen to the expanded use of nuclear power has focused on the reprocessing and storage of radioactive waste. Although the importance of the problem was recognised when West Germany first began using nuclear energy, the necessary political measures to deal with it were not set in motion. What is more, after 1980 it may not be possible for West German fuel elements to be reprocessed in France or Great Britain. In both countries there is growing opposition to the expansion of reprocessing capacity, especially for foreign fuel. Germany's present contracts run out in 1979.

Faced with this problem, the West German government has resolved to authorise the building of new power stations only if the safe disposal of fuel elements can be guaranteed from the start. It has plans for a *entsorgunzentrum* ('service centre'), which could reprocess the fuel elements from all West German nuclear power plants and store the radioactive waste products in salt deposits for hundreds of years. The site chosen for the centre is Niedersachen, but a fierce argument has flared up locally which may have far reaching effects on the construction of nuclear power stations in other parts of West Germany. Yet unless the service centre can be established, the expansion of West Germany's nuclear power capacity will be halted. Government leaders and the opposition therefore feel that they must jointly take steps to ensure that a centre is built.

Overtaking Britain

At the end of 1976, 13 nuclear stations were in operation in West Germany, with a total output of 6,500 MW. West Germany has overtaken Britain in terms of nuclear power capacity and is the leading user of nuclear energy in the EEC. A further 17 nuclear power stations are proposed, some of which are already under construction. There were plans for 50 by 1985, with a total capacity of approximately 45,000 MW, but because of the recent public protests the construction of some planned nuclear power stations has been postponed in certain areas, and this figure now seems utopian. Experts now believe that about another 25 stations will be operational by 1985, with a total capacity of approximately 22,000 MW.

The government believes that the country faces an electricity shortage in the 1980s and in spite of the current difficulties, large scale research is going on to develop more advanced reactors. Some DM2,000 million each year are allocated for nuclear energy research, mainly for developing a fast breeder and a high temperature reactor. For many years there has been bitter argument over the necessity for the fast breeder, and this has grown even more bitter during the past few months. It remains doubtful whether an acceptable site can be found, and the special security problems make it more unlikely that the public will ever accept it.

Compared to the internal difficulties, discussion of Germany's role in international trade in nuclear technology has been comparatively limited. The controversial deal with Brazil, providing eight nuclear power stations, a reprocessing plant and an enrichment plant by 1990, was originally welcomed by all parties in the Bundestag, and the government and opposition still agree that it is necessary. The Carter Administration is objecting to the reprocessing and enrichment plants because it fears they will provide Brazil with the raw materials for an atomic bomb, and has endeavoured to pressure Brazil too. With reports now of US hold-ups in supplies of enriched uranium to West Germany, nothing is certain, but the general public seems to accept that the West German-Brazilian treaty should be adhered to in its original form. Their more immediate concern is with the domestic implications of a domestic programme. And that concern is likely to be fuelled still further in the future. ☐

UNITED NATIONS

Preparing for 1979

A Special Correspondent reports on preparations for the United Nations Conference on Science and Technology

THE appointment in January of Mr Joao Frank da Costa of Brazil as Secretary-General of the United Nations Conference on Science and Technology, which is scheduled for 1979, has enabled preparations to get under way. Sitting as the Preparatory Committee for the Conference, the 54-nation Committee on Science and Technology for Development gave a mixed reception to Mr da Costa's views on the organisation and timing of the conference preparations. He secured agreement, however, on several vital points, the most important of which is perhaps that he should have as free a hand as possible in the selection of the conference secretariat.

Kurt Waldheim, the UN Secretary-General, had stated that the post of Deputy Secretary-General of the Conference should be held by Dr Klaus-Heinrich Standke, the Director of the Office of Science and Technology in New York, and that his staff should form the core of the conference secretariat. From the first, Mr da Costa made it clear that he could not accept this arrangement, especially as Dr Standke was expected to double up two responsible jobs from now until the conference. No deputy as such has been appointed; the Executive Secretary of the Conference, Mr Hans Einhaus, who has lately represented the Office of Science and Technology in Geneva, is holding this position in an acting capacity.

Da Costa was less successful in persuading the committee of the practicability of some of his other ideas, such as the suggestion that each member state should produce three preparatory documents for the conference. If previous performance is anything to go by, many governments will have difficulty in producing a single really useful paper, as now requested, although the option to produce more remains open for those who can. Regional papers will also be prepared by the several UN Economic Commissions. With those from the other members of the UN system and from major organisations outside the UN, these will make up a considerable amount of documentation. To offset this, the number of meetings, seminars and so on suggested for the preparatory period will be reduced; the suggestion that the conference secretariat should be regionalised was also dropped.

No precise agenda is expected until this time next year, but the general objectives of the conference are already well defined. They include: the adoption of concrete decisions on ways of applying science and technology, as a strategy aimed at economic and social development "within a time frame"; strengthening the technological capacity of the developing countries; the adoption of means for the utilisation of science and technology in solving the problems of development; and the provision of "instruments of cooperation" to developing countries, for solving socio-economic problems that cannot be solved by individual action.

In general, it does seem as though the agenda will be action-oriented; one thing da Costa stressed was the need to avoid the "ritual complications" inherent in the preparations for all such conferences—the ritual of producing documents and of setting-up institutions do not of themselves solve problems, but are only tools to that end. In general, the objective of the conference will be to assess and redefine the role that science and technology has to play in development. Moreover, as seen by da Costa the preparations themselves can help towards the definition of a unified policy for science and technology within the United Nations system.

One other point on which da Costa did not get his way was in the location of the conference secretariat. He had asked that it be set up in Geneva, but this was overruled, the majority of delegations preferring New York, where they can oversee, if not interfere in, the conference preparations. Many regard this as unfortunate. One of the reasons for the success of the Environment Conference in 1972 was the insistence of Maurice Strong, as Secretary-General, that his headquarters should be in Geneva, away from the UN bureaucracy.

The New York siting could also prejudice really close collaboration on the part of the other members of the system, although their involvement has been one of the avowed intentions of those who suggested the conference in the first place. Geneva is central to these organisations—UNESCO in Paris, UNIDO and IAEA in Vienna, FAO in Rome and, in Geneva itself, WHO, WMO, UNCTAD and ILO. It is in these organisations that the bulk of international knowledge and experience in applying science and technology lies, and the possible economies of having the secretariat in New York may well be offset by a loss of their close collaboration and good will. □

CANADA

Support for alternatives

David Spurgeon reports from Ottawa on Canada's interest in alternative energy sources

CANADA, a country once thought to possess fabulous natural gas and petroleum supplies, is now carefully assessing its renewable energy resources. The government has recently increased the funds available for research on tidal power, wind power, biomass and solar energy. And the whole subject was highlighted at a recent meeting of the Parliamentary and Scientific Committee sponsored by SCITEC, the Association of the Scientific, Engineering and Technological Community of Canada. It was the second meeting of the committee, which was formed to bring parliamentarians and scientists together, and in spite of scepticism that this could be done, both meetings were well attended.

One of the most interesting energy potentials discussed was the Bay of Fundy's tidal power. Separating the two Maritime provinces of Nova Scotia and New Brunswick, the Bay of Fundy possesses one of the world's largest tide ranges. A. N. Karas, assistant director of planning for the Electrical Engineering Branch of the National Energy Board, said that although the last detailed study in 1968 concluded that Fundy power projects were uneconomic (albeit feasible), significant increases in power generation costs had helped the two provincial governments and the federal government to agree in 1975 to re-evaluate such schemes.

The conclusion was that the combined market for a 7,000 MW tidal power plant—in the Maritimes, in the contiguous areas of Canada (mainly Quebec), and in the Northeastern United States—would by 1990 be more than ten times the capacity of the plant, or about 77,000 MW, and that such a plant could be brought into operation by that time. A survey indicated that the anticipated peak load in the Maritimes would grow from 3,216 MW in 1980 to almost 23,000 MW by the year 2010. For Quebec, the peak demand would be 18,682 MW in 1980 and 133,000 MW in 2010. And in the Northeastern United States, the figures would be 18,000 MW in 1980 and 87,500 MW in 2010. Thus the full output of the plant could be used.

The energy displaced by a tidal power plant in the Maritimes, furthermore, would be predominantly high cost oil-fired and some coal-fired energy, the latter mainly in Nova Scotia. "In 1990 tidal energy would displace about 4,000 GWh of oil-fired generation and 500 GWh of coal-fired generation," Mr Karas said. "This is equivalent to about an annual savings of 6 million barrels of oil and 300,000 tons of coal. By the year 2010 the corresponding annual fuel savings have been calculated to be about 9 million barrels of oil and 600,000 tons of coal." To serve the tidal plant's export markets, extra high voltage transmission lines (735 or 750 KV) would be required.

The scheme has considerable appeal to residents of Nova Scotia, who have been hard hit by the recent increases in oil prices. Residents of that province pay some of the highest prices in the country for home heating. The president of the Nova Scotia Power Corporation, L. F. Kirkpatrick, was quoted in the *Globe and Mail* as saying that, based on recent construction cost estimates of between $1,300 million and $1,700 million, power could be produced at one or other of the Bay of Fundy sites for between 18 and 29 mills per kilowatt. Currently, oil-produced electricity costs almost 20 mills.

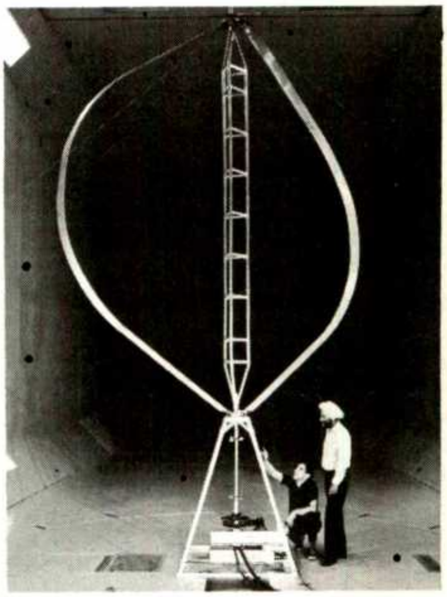
Dr E. P. Cockshutt, co-ordinator of the National Research Council of Canada's Energy Project, gave a cautious but positive forecast for the utilisation of solar energy in Canada. There is sufficient solar energy available in all the reasonably populated regions of Canada to make it a useful resource, he said, giving the lie to those who have played it down in the past. But there were unique features of climate and geography that necessitated a distinctly Canadian programme.

An attack on the technical problems of durability and cost was the most important priority for the next two or three years, Dr Cockshutt said, noting that "popular enthusiasm for solar heating presently outruns the technical and commercial realities." Large-scale commercialisation of solar heating is at least five to ten years away, but it is expected eventually to become a billion-dollar-a-year industry, he said.

Total radiation outside the earth's atmosphere available to a properly-oriented receiver amounts to about 1,400 watts m^{-2}, and that actually received on a horizontal surface at ground level in most of Canada is about one-tenth that (150 watts m^{-2}) on a year-round average basis, Dr Cockshutt said. Even the sunniest parts of the world receive less than twice as much, or about 250 watts m^{-2}. And with properly inclined collectors, the difference would be reduced. But it is because of the extremes of seasonal variation that a Canadian solar energy programme must differ greatly from those in countries close to the equator. In addition, the reflective properties of snow-covered ground differ distinctly from those of vegetation.

Professor H. M. Lapp, of the University of Manitoba's Department of Agricultural Engineering, called biomass a major energy source for Canada in view of the magnitude of its production annually. "The energy available in animal waste, crop residues and forestry waste represents approximately 6.72, 2.74 and 9.46% of Canada's national energy consumption, or a combined biomass energy potential of 18.92% of Canada's national energy requirement," he said. "Such a significant component of Canada's national energy requirements available from renewable sources should be examined carefully for the feasibility of economically viable development." Considering wood alone, he said it had been estimated that ethanol/methanol fuel production potential from wood was about 2½ times Canada's current annual consumption of motor gasoline and approximately 110% of its total gasoline plus fuel oil consumption.

The head of the NRC's low speed aerodynamics laboratory, R. J. Templin, estimated that, with average one- to two-mile spacing between megawatt-sized wind turbine power plants with a total height of about 100 m, the average wind power available over the whole of the country was about 130,000 MW (overall conversion efficiency 15%). If it was assumed that suitable sites were limited to areas within 150 km of an existing network, the available average power was reduced to about 60,000 MW—about twice Canada's national electricity consumption in winter months. Even without energy storage, "it appears that wind energy constitutes a very large *theoretical* resource in Canada," he said. The main obstacles to large-scale wind energy development were the need to demonstrate long-life reliability and to reduce capital costs.



Wind up: turbine in tunnel

A number of small-scale wind power projects are currently in progress in Canada, including several at the Brace Research Institute, Montreal, and a rotor designed by Brace installed by Hydro-Quebec's Research Institute for experiments on compressed air storage. The only large-scale project is the 200 kW vertical axis turbine now being erected by Hydro Quebec on the Magdalen Islands, one of the windiest sites in Canada. Several new versions of the turbine are under development at two Canadian companies with government funding assistance.

Only days before the SCITEC meeting, the federal government showed its interest in renewable energy resources by announcing that research in the area had been awarded the largest share of a $10 million increase in federal funding for 1977–78 for energy research. A Renewable Energy Resource Branch has been established within the Department of Energy, Mines and Resources, and a National Advisory Committee on Conservation and Renewable Energy is being created.

There was a $4.4 million increase for renewable energy research (including solar, wind, biomass and the use of heat pumps); energy conservation was allotted $3.7 million more; coal, heavy oils and oil sands research was increased $1.5 million; and transportation and energy transmission received an increase of $460,000. The increases will bring total federal energy R&D funding to approximately $138 million in the next fiscal year. □

VIKING

Give us a call, says NASA

Alex Dorozynski reports from Paris on the Viking symposium held there last week

NASA's next Mars package will be launched from Cape Kennedy in January 1984. It will carry a roving laboratory capable of covering at least 100 km and perhaps as much as 1,000 km of the planet. The orbiting satellite will contain 'penetrators', to be implanted at and to transmit information from selected locations, as well as remote sensing and transmission equipment. Lodged several metres into the Martian soils, the penetrators will record seismic activity and will try to determine the chemical composition of Martian soil below the surface. No attempt will be made to bring soil samples back to Earth; the earliest date for a rational sample return mission, rather than an indiscriminate 'grab sample' attempt, is 1988.

This schedule is not an official one, but it sums up the consensus of opinion at last week's symposium. The symposium involved senior scientific and management personnel of the Viking programme, the European Space Agency and the French National Centre of Space Studies. The Viking team will now tour several European countries, including the Soviet Union, to inform interested scientists of the latest Viking results and to emphasise that NASA planetary exploration programmes are open to international participation.

According to the Viking chief project scientist, Dr Gerald A. Soffes, no part of the schedule is in the approved stage. But the outlook is favourable indeed. By any standards—science, technology, public appeal—Viking has been an outstanding success, and data is still pouring in from the two landers and the two orbiters. These will all be kept at work for at least another full year. One single orbiter may continue to relay information from both landers, while the other will be switched over to different orbits in order to roam the surface of the red planet with its remote sensing equipment.

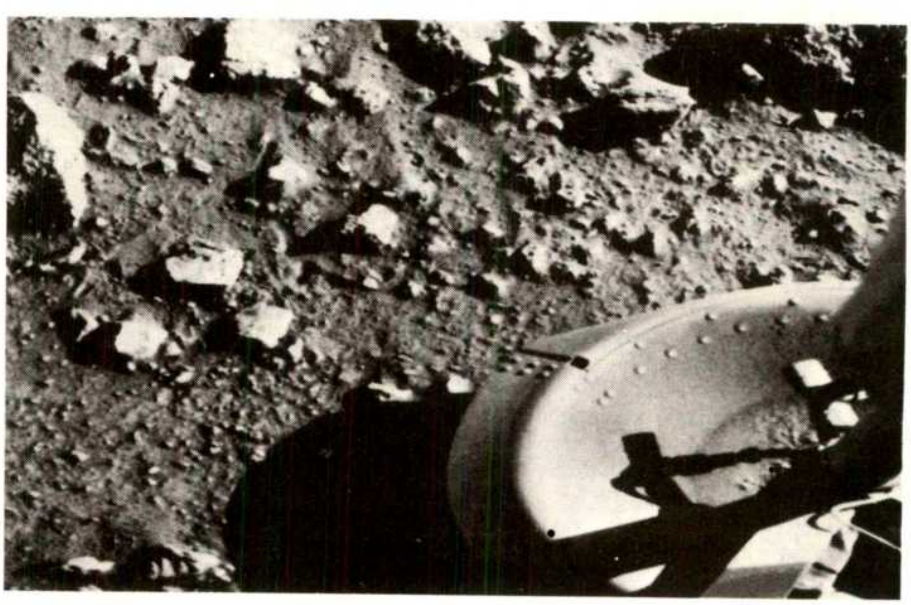
President Carter has recently proposed an increase in NASA 'study money' for 1978 (the increase awaits Congressional approval) but the agency does not seem to want to go to Mars with another Viking just for the sake of it; rather it wishes to exploit the massive flow of data to prepare the next Viking generation. The 1979 'astronomical window' to Mars seems too close for this, so the project for early 1984, even though it is not optimal from the energy viewpoint, has been adopted as a goal by the study team and this is already at work.

Dr Soffes and his colleagues made a point of inviting non-American guest scientists to participate in the study of Viking data and the elaboration of future missions. According to A. Thomas Young, the Viking missions' operations manager, participation would include the elaboration of scientific experiments, instrumental design, and perhaps even the loading on board of an experimental package—provided of course it fits into the overall package. Dr Young suggested that the first proposals be made to the NASA by mid-May this year, so that planning of the still-hypothetical 1984 mission could start early in October.

Meanwhile all Viking data is being made available to interested scientists. Major reports have been published in three issues of *Science*; these have not apparently been found sufficiently detailed and complete by some specialists, so a thorough review is now being prepared, including most recent data, for publication in the *Journal of Geophysical Research* in September.

Dr Soffes also hopes for an international Viking conference similar to the one that followed the Mariner mission, but, he says, "it is not easy to put together or to know when it should happen." In the meantime limited discussions on specific aspects of Viking results will be held during other meetings. These will take place, for example, at the lunar samples meeting in Houston in March, the meeting in Kioto in June of the International Biological Society for the Study of the Origin of Life, and the pulsar meeting in Tel Aviv, also in June. Scientists are also being encouraged to contact NASA directly concerning aspects of Viking in which they are particularly interested.

New data is coming in so rapidly that publications cannot keep up without delays of six months or more, and the participants in the Viking symposium at the *Palais de la Découverte* in Paris were given more than enough to whet their appetites. On the menu: the Mars quake, registered during the primary mission, which took place some 50 km away from the landing site, and was measured between 2 and 3 on the Richter scale; the first close range photograph of Phobos, one of Mars's small moons; the decreasing atmospheric pressure, now increasing again as winter approaches in the northern hemisphere; the verification of Einstein's general theory of relativity; the phenomenon of Mars' dusts storms and the unusual erosion patterns that have been photographed and still remain a puzzle. Finally, of course, there are the biology experiments, which Dr Leslie Orgel, Head of the Viking molecular analysis team, described as the most positively negative, adding that in fact they had given no answer; Viking had landed in one of the "most desolate positions on Mars". Other sites will be explored during the next mission; but Mars conditions, or at least some of them, are now being re-created in the laboratory to find out whether earthly life forms can survive in them. As other sites may have conditions entirely different from the ones at the Viking landing sites, there is still hope for life. "We may have found that where it's red, it's dead" quipped Dr Orgel; but Mars is red all over. ☐



NASA

Back to 1976 : a view from Mars

USA

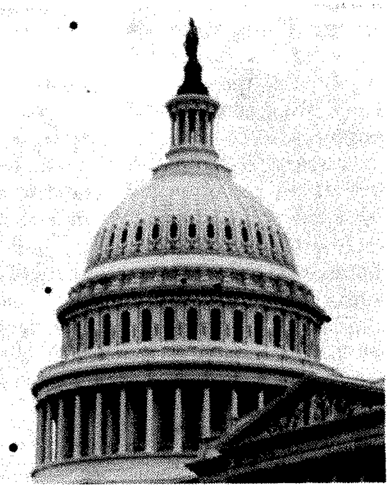
● Congress has already begun to whittle down the hefty budget increase for basic research proposed by President Ford in his valedictory budget. A key House subcommittee last week substantially reduced the budget request for the National Science Foundation (NSF), and recommended some shifts in priority among NSF's programmes. Though the sub-committee's actions are likely to be revised as the NSF budget bill moves through the rest of the Congressional budget process, the proposed reductions at least sound a warning that Congress isn't going to rubber stamp the research and development proposals this year.

Ford has recommended that basic research in general be given a budgetary shot in the arm to help restore some of the inflationary losses incurred during the past few years. It has been estimated that real support for basic research in the United States shrank by about 20% between 1967 and 1975, and Ford accordingly proposed that federal support be increased next year by more than 9% —well above the anticipated 6% inflation rate. NSF's budget, in particular, would have gone up by more than 12% under Ford's proposals. Those recommendations were left unchanged by President Carter when he submitted his budget revisions to Congress late last month.

Last week, however, the House subcommittee on Science, Research and Development, which is usually friendly toward NSF, approved an authorisation bill for the foundation which would provide an increase of about 9%—enough to keep NSF a step ahead of inflation, but substantially less than the Ford budget proposal. The subcommittee, moreover, has shifted funds within NSF's total budget in such a way that the programme of Research Applied to National Needs (RANN) would bear the brunt of the reductions, while the foundation's education support programmes would be given more money than Ford had requested.

The RANN programme would be given about the same overall budget as it received this year, but the subcommittee has recommended that a sharply increased proportion of RANN funds should be spent on earthquake research. Other RANN projects would consequently be cut back. Outside those two areas, the subcommittee has essentially recommended that NSF's programmes be given cost-of-living increases.

The subcommittee's action is only the first stage in a protracted budget process. The subcommittee bill will be taken up by the full Committee on Science and Technology this week before being sent to the House itself and, on the senate side, a subcommittee chaired by Senator Edward Kennedy has just completed hearings on NSF's authorisation bill; it is expected to report its own version soon. Appropriations committees in both the House and Senate will then take up the measure.



It is thus likely that the subcommittee's bill will be modified considerably as it progresses through the rest of the Congressional mill, but the proposed reductions nevertheless suggest that NSF's budget may be in for a bumpy ride through Congress this year.

● Another distinguished scientist has been appointed to a top-level post in the Carter Administration. Donald Kennedy, professor of zoology at Stanford University, was last week named Commissioner of the Food and Drug Administration (FDA), a post which has been occupied by physicians for the past 12 years.

The appointment is something of a surprise since Kennedy has had little direct experience in the political minefield of drug regulation. FDA is constantly caught in a fierce crossfire between the drug industry, consumer advocates and Congressional critics. It has been chronically short of funds to carry out its mission or regulating the powerful food, drug, cosmetics and medical devices industries, and its own research enterprise is generally acknowledged to be relatively low in quality. Kennedy will clearly have his work cut out for him.

A neurophysiologist, Kennedy's political star has been rising rapidly in Washington in the past few years. Elected a member of the National Academy of Sciences in 1972 at the age of 40, he was chairman of an Academy committee which last year produced a massive and widely-publicised report on pest control problems. Late last year he was appointed a senior consultant to the newly established Office of Science and Technology Policy (OSTP), a job which took up half his time and kept him shuttling back and forth between Washington and Stanford. While at OSTP, Kennedy is said to have played a major role in securing a substantial increase for agricultural research in President Ford's final budget. Otherwise, his experience in Washington politics has been limited.

● An international coalition of scientists, environmentalists, theologians and philosophers has been formed to seek a worldwide moratorium on most uses of recombinant DNA techniques and broader public discussion of the ethical and social implication of genetic engineering. The coalition, whose formation was announced at a press conference in Washington on Monday, includes among its sponsors Sir MacFarlane Burnett, an eminent Australian immunologist and Nobel Prizewinner. Other sponsors include Aurelio Peccei, founder of the Club of Rome, Lewis Mumford, author and philosopher, George Wald, and a number of environmentalist organisations and church leaders.

A statement endorsed by the group, which calls itself the Coalition for Responsible Genetic Research, notes that "genetic and molecular biological research is rapidly providing the basis for the practice of genetic engineering". It continues: "The continuation of this research without public understanding and approval, and in fact without a full comprehension of its potential by most of the involved scientists, poses a worldwide danger which is intensified by the fact that industrial investment in the developing genetic technology has already begun".

Citing possible health hazards from current research, including "the spread of cancer or the creation of new diseases", the statement calls for a moratorium "on all research that would produce novel genetic combinations between distant organisms which have not been demonstrated to exchange genes in nature". The moratorium should stay in effect, the coalition argues, while the ethical implications of the research are examined and the dangers assessed in public discussions.

Colin Norman

View and review

The development of a comprehensive UK energy policy has come in for further analysis in the past week. Chris Sherwell reports

BRITAIN'S Energy Secretary, Mr Anthony Wedgwood Benn, who has already taken steps to broaden the basis of consultation on the country's energy policy by holding an energy conference and proposing an energy commission, is now considering the possibility of publishing a Green Paper (discussion document) later this year to widen the debate still further. The suggestion is contained in a memorandum from Mr Benn which accompanies the energy policy review document that the Department of Energy has produced for the National Economic Development Council.

The document crisply summarises the country's prevailing energy policies. Short-term problems, arising from an excess of capacity, emphasise the difficulties of power plant manufacturers, the possibility of a coal surplus and the need for a gas gathering pipeline to harness the Northern North Sea. The suggested long-term strategy emphasises the Plan for Coal and coal conversion research, the need for a flexible oil depletion policy and a long-term gas policy, the need for access to necessary reactor technology including the fast breeder, and the benefits of conservation and renewable energy sources. The finances and pricing of the nationalised energy industries also need to be put on to a proper economic basis.

Last week the Royal Society released its long-awaited report on the government's discussion document published last year, *Energy R&D in the United Kingdom*. The Society also published a report on R&D strategy for offshore oil and gas technology. The most significant point to emerge concerned the fast breeder reactor. Coal could not alone satisfy future demand, it was argued, and the proposed demonstration commercial breeder (CFR-1) should be given sufficient approval to allow all planning and practical studies to start immediately; the country's lack of uranium sources meant that any credible nuclear policy had to be based on the breeder and did not imply the inevitability of a breeder programme.

Support for R&D on alternative sources was urged, particularly in power and solar power; wind and geothermal energy were less enthusiastically received. ☐

THE severe drought in the Western United States has led to widespread calls for rain- and snowmaking, and has even caused one state, Idaho, to threaten legal action if a neighbouring state, Washington, interferes with the weather. Is there, however, any reason to have much confidence in rainmaking activities? Many of those who work in or close to the field of weather modification are still sceptical of our ability to affect precipitation.

Most effort in weather modification has been devoted to adding to the population of natural ice nuclei. These are extremely rare particles (only about one in a billion atmospheric particles is an effective ice nucleus at warmer than −15 °C), although these rare nuclei can sometimes generate many secondary particles. Silver iodide is still the main artificial nucleating material, although experimental evidence on the mechanism is ambiguous. Distinct from ice nucleation is the process of altering populations of cloud condensation nuclei, and some interesting work has been done in India using sodium chloride. There is still no strongly preferred method for launching nuclei—airborne and ground generators continue to be used.

An immense amount of cloud-seeding has been done in the past 25 years, but most has been by commercial enterprises for which little satisfactory documentation exists. Detailed studies by governmental organisations with attempts at statistical analysis have, however, been conducted in the United States, Canada, India, Israel and Australia and are summarised in a valuable document, *Weather and Climate Modification* (US National Academy of Sciences, 1973).

Changing weather

BACKGROUNDER

Experiments have used amounts of silver iodide of up to 1 kg per hour. The major problem has always been that of data analysis, as ideally, trials should be fully randomised. Even when this has been done statistical tests, on which there is still much discussion, show occasions when results are inconclusive and even occasions of diminished precipitation. The above-mentioned report, however, was more optimistic about one experiment, Climax in Colorado, in which cold orographic winter clouds were seeded; precipitation, it says, can be increased by substantial amounts (35%) and on a determinate basis.

Not all weather modification experiments have been specifically devoted to rainmaking. In Florida, a major experiment has been underway for several years in the field of 'cloud management'. Massive seedings of up to 1 kg per cumulus cloud are intended to release large amounts of latent heat as supercooled water is rapidly turned to ice. The latent heat increases the buoyancy of clouds and hence their lifetimes during which they may grow or merge.

Further, there has been extensive activity, centred on Colorado, to modify hail which accounts for $700 million of damage in the United States every year. A strategy already adopted in the Soviet Union is to increase by a factor of up to a thousand the number of nuclei in the hail-producing part of a cumulonimbus cloud by launching shells or rockets packed with silver iodide which explode inside the cloud. The hope is that many small hailstones rather than a few large ones will fall. Soviet work has extended well beyond the research phase and annual savings running into tens of millions of roubles have been reported. Work in France, Switzerland and Kenya has yielded mixed results, again with problems of randomisation, but the National Hail Research Experiment initiated in 1971 in the United States has yet to bear fruit.

IN BRIEF

More trouble for dissidents

Seven Moscow Jewish activists, all members of the Voronel/Azbel' seminar and/or the Helsinki monitoring group, have had their homes searched unusually thoroughly by the police. The seven are the cyberneticist Aleksandr Lerner, Josif Beilin, a mathematician, Ida Nudel, an economist, and the engineers Vladimir Slepak, Anatolii Shcharanskii, Boris Chernobil'skii and Mikhail Kremen. An open letter in *Izvestiya* signed by Dr Senya Lipavskii, a former associate of these groups, accuses them of being financed by CIA funds. Lipavskii also claimed that during their protest hunger strike of March 1974, the sinologist Vitalii Rubin and the chemist David Azbel' did, in fact, eat regular meals. (Both Rubin and David Azbel' have since emigrated, Azbel' in 1974 and Rubin in 1976).

Dissident circles in Moscow associate the new repressions with a recent article in *Pravda* urging political vigilance "as never before". In Warsaw, meanwhile, the latest batch of arrests of members of the Workers' Defence Committee has included the mathematician Jan Lytinski and Mieczyslaw Grudzinski, a computer engineer.

Argentina–Peru deal

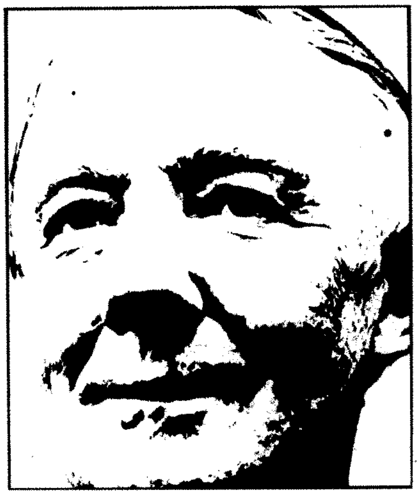
Argentina's growing role in Latin America's development of nuclear power was given another boost at the end of last week when she signed an agreement with Peru to build a 10 MW research reactor there. The agreement, reportedly involving a $50 million budget, covers design, equipment and training of local scientists. Argentina herself has a 300 MW reactor in operation, and a 600 MW reactor under construction. Recently she announced her support for Brazil's efforts to maintain the controversial deal with West Germany, the original source of guidance for her own programme.

BNFL: another step

Plans submitted to Cumbria County Council by British Nuclear Fuels Ltd (BNFL) for expansion of existing Magnox reprocessing facilities and for facilities to develop its Harvest waste solidification process were, as expected, quickly accepted by the council's planning committee last week.

BNFL split into two its more controversial oxide fuel reprocessing plans. The part covering construction of the plant is now expected to be called in for a public inquiry. The other part, relating to the provision of storage facilities for incoming fuel, will, BNFL says, not prejudice any decision on the plant itself.

Grade expectations



KENNETH MELLANBY

SCIENCE is being taught today in British universities, polytechnics and colleges in many different ways. We still have special honours degrees, where one subject is dealt with 'in depth', with the intention of producing specialists. It is generally agreed that brilliant students, particularly if they intend to follow a career in their speciality, may thus be well served. However, some departments now offer such a variety of optional courses that the result may be unrecognisable to the traditionally minded. Zoologists may never study a whole animal, botanists may know little about common plants. Even when such fashionable absurdities are avoided, many would agree that less gifted students, only able to scrape a pass, are better served by more broadly based instruction.

The 'interdisciplinary degree', however, is not new. Fifty years ago Part One of the Cambridge Natural Science Tripos (taken in three subjects), or the similar London University General Honours course were familiar examples; both entitled their holders to an honours BA or BSc. The degrees were considered suitable for the less able, or as a preliminary to specialisation in a single subject.

Today, there is a much wider choice. Modular degree courses may allow students to choose combinations of subject which appear illogical to conservative academics. Even when, as is true of most colleges, students are sensibly counselled, so that the subjects studied are reasonably compatible, those entering these courses may have somewhat doubtful job-prospects, particularly serious at a time of graduate unemployment. It would be little consolation for a prospective chemist to be told that he is now better suited to enter "the upper reaches of the Civil Service, banks, the highest positions in industry" because he is now better educated than his contemporaries studying classics (if his course fits the criteria suggested by Sir Hermann Bondi, *Nature* 27 January 1977) when the Royal Institute of Chemistry finds itself unable to recognise his qualifications.

This was why the Council for Science and Technology Institutes, which coordinates the work of the recognised bodies in Britain, held a meeting in London recently to discuss how multidisciplinary degrees could qualify their holders for admission. It was clear that all the institutes were anxious to find ways to allow these graduates to qualify, provided this did not lower their standards. Most give credit for those parts of the course which are relevant, and suggest how essential gaps may be filled. As all the institutes only elect graduates after several years of experience in their subject, the length and nature of this experience can be adjusted to overcome deficencies. It is clearly important that all teaching departments should know, in advance, how new courses are likely to be viewed by the professional institutes, as well as by prospective employers.

Membership of professional institutes may become increasingly important, as these qualifications become the means by which scientists are recognised within the Common Market. It is also clear that the greater difficulty a candidate may have in being accepted the more valuable membership will be to him. The institutes must be fair and sympathetic in all cases, but must also be seen to be maintaining their standards. They must always remember Groucho Marx, whose applications to join an exclusive club were repeatedly blackballed. Eventually he was informed that he had been successful, upon which he asked "Who would want to join a club which admitted a bum like me?"

correspondence

The teratogenic effects of dioxin

SIR,—Alistair Hay (10 February) states that many pregnant women from the dioxin-contaminated district of Seveso have sought terminations outside Italy. Some will have to come to Britain: UK statistics should reveal whether relatively more abortions were performed on Italian women in 1976 than 1975.

In view of the highly teratogenic activity of dioxin in animals, and the total absence of information for our own species, I share Dr Hay's concern that no organised steps have been taken to examine aborted foetuses for possible malformations. I would urge that some code of practice be agreed, if possible for Europe as a whole but at least for Britain, to ensure that all foetuses aborted as a result of any suspected contamination of the environment should be examined by an experienced pathologist and compared with a matched control series. We may be too late this time: but Seveso is unlikely to be the last accident of its kind.

Yours faithfully,
ANNE MCLAREN

MRC Mammalian Development Unit,
University College, London

Journal abbreviations

SIR,—I agree with Adrian Smith (10 February, page 492) that the saving in typesetting does not in itself justify the use of journal abbreviations. I suggest, however, that the real problem lies not in abbreviating but in establishing a correct and unambiguous title. Here the British Standard is of no help, but the *World List of Scientific Periodicals* is invaluable, for journals published up to 1960.

The examples of ambiguous abbreviation cited by Mr Smith do not come from the *World List*, where there is a clear distinction between *J. math. Phys.* and *J. Math. Phys.* Had they existed in 1960, *Industrie minérale* would have become *Industrie minér*, while *Industrial Minerals* became *Ind. Miner.* Even in the annual supplements published since 1960, which have unfortunately abandoned the principles of the fourth edition of *World List*, *Ind. Miner.* (*Fr*) is not the same as *Ind. Miner.*

The *World List* gave a standard for journals with multilingual titles, and distinguished, if distinction be thought necessary, between three journals called *Nature*.

Correct identification of current journals will eventually be possible by the use of International Standard Serial Numbers, though whether this will reduce the chore to authors and editors remains to be seen.

Yours faithfully,
J. E. M. HORNE

Windermere

Charged plumes

SIR,—Contrary to the report of Jennings and Jones on high electric fields from industrial stack plumes (November 18, 1976), the electrical effects in the atmosphere caused by electrostatic precipitators are well known. Those working in the field of atmospheric electricity are aware that plumes emanating from chimneys equipped with precipitators contain large numbers of charged particles which can be detected at a considerable distance from the chimney[1].

Much of the charge may be carried on solid particles which somehow have escaped capture on the precipitator surfaces. We think that some fraction of the charge is also carried by water molecules from the combustion products in the industrial operation and of course there will be some small ion generation from the breakdown of other gases near the high voltage portion of the precipitator.

We have measured effects of chimney plumes with equipment carried in a manned aeroplane[2,3,4]. Among other results, we observed both the horizontal and vertical atmospheric electric field components up to 4,000 feet above the chimneys on calm days, when thermal convection of the plume was more pronounced than motion downwind. Rowland[5] came across the plume phenomena in 1973 when making measurements in a clear air turbulence study.

Vonnegut *et al.*[6] purposely generated clouds of charged oil droplets with a device similar to an electrostatic precipitator and reported extremely high local electric fields which caused point corona discharge currents and other high-field effects on bushes, structures, people, etc. He also levitated a charged cloud of water droplets below the oil cloud.

To the extent that charges generated in this manner (by chimney precipitators) can somehow become transferred onto high mobility carriers, the authors may be right in asserting that there is a possible contribution to the earth's charge balance. We doubt that the low mobility, charged solid particles contribute directly, but the high mobility charges which they may generate by pulling point discharges from earthed structures, might. The first result of this point discharge current in the atmosphere, of course, will be to help discharge the chimney plume; no doubt this is partly why the electrical effect of the plume is diminished as it travels away from the precipitator.

The observation of a possible hazard from sparking in the near vicinity of such plumes is well taken, and the cement and electrical power industries should be interested in further investigation into this likelihood.

Yours faithfully,
MAYNARD L. HILL

Bird at Pompeii

SIR,—T. E. Thompson (27 January, page 292) surely owes an apology to the anonymous artist of Pompeii. The little bird he portrayed sitting on a rock overlooking the sea is clearly a composite representation of all those passerine migrants of the type known to Americans as 'confusing fall warblers' which are still trapped and eaten on a vast scale all round the Mediterranean coastline. It is interesting that they are the only terrestrial delicacy considered worthy of inclusion in a picture of local specialties. They are of course those 'nightingales' whose tongues formed the favourite diet of the Roman emperors.

Unsolved problems in nuclear structure

from Otto Kofoed-Hansen

IN preparing the balance sheet for any particular branch of science, much subjective argument is involved. So what follows is my very personal stocktaking of nuclear physics—where do we need more experimental information?

Where exactly is the yrast line?
Quoting Bohr and Mottelson (*Nuclear Structure* **II**, Benjamin, 1975) "the lowest level of given spin is referred to as an "yrast" level (Grover *Phys. Rev.* **157**, 832; 1967) The word appears to derive from the old Germanic *wor*, which developed into the English *weary* and the Nordic *ørr* (modern Swedish *yr*, modern Danish *ør*), meaning dizzy. The form *yrast* is the naturally constructed superlative of *yr*" (In other disciplines of physics the name "the lowest Regge trajectory" appears more natural)

For a given nucleus composed of Z protons and N neutrons, (mass number $A=Z+N$) there exists a multitude of possible states. The states are characterised in their energy content and in sets of quantum numbers (such as spin, I, which characterises the angular momentum of the nucleus as a whole) For each spin value, I, there exists a lowest energy content below which no (N,Z) nucleus of this spin can be formed. This lowest energy limit is called the yrast line—at this line all the energy available is used to make the nuclear structure in question spin. For simple heavy nuclei there is also a maximum energy content beyond which the nucleus will fission, centrifugal forces will split it. Thus there exists for all NZ combinations and all values of I a region limited on one hand by fission and on the other hand by yrast (dizziness). Large groups of nuclear physicists are attempting to pin down these limits and to understand them in terms of nuclear models. The tools envisaged are heavy ion accelerators and all possible refinements in detector techniques The aim is to create very large spin states of representative combinations of N and Z and to watch the details of the decays of these states The mere fact that N, Z and I can vary within a relatively wide range means that this is a vast region of research. The interpretation is forseen in terms of collective nuclear models, but bordering on those limits where every single nucleon in the nucleus carries as much oriented angular momentum as it can get away with. The next question thus follows quite naturally.

Where is the borderline between continuum descriptions and individual particle descriptions of nuclei?
By 'individual particle description', I understand a description where the nucleus of mass number $A=Z+N$ is considered as a many-body system of A interacting nucleons (Z protons and N neutrons). This should not be confused with an 'independent particle description', where a nucleus is described as usually one (or a few) particles moving in an average field created by the rest or by the totality of nucleons in the nucleus and described by semi-empirical parameters. Whereas I personally consider an "individual particle description" as a fundamental approach, I must admit the technical difficulties encountered. For practical purposes I am quite willing to use the semi-empirical approximations. I have, however, a (vain?) hope that some day we may succeed in using the fundamental approach. It is clear that the yrast region is such a border line, because when this region is reached the nucleus spins as fast as possible with a finite number of constituents having oriented angular momenta. But are there other ways of assessing such limits?

What is now the major difference between the results obtained with a genuine many-particle description and with a continuum model? To my mind the major difference is to be found in the number of levels of this or that class which obtain An example of this can be found apparently in the number of levels in a rotational band. A few years ago an attempt was made to answer such questions. I feel that it would be interesting to pursue this matter in much greated detail. Results of this kind would also be of interest for the subject of the next question.

Where do the mesonic degrees of freedom come in?
Perhaps this question may be most easily discussed by considering a few historical facts. After the Second World War nuclear physics had become an 'important science'. Many physicists were optimistic that the ultimate solutions to problems in nuclear physics would soon be found. One such attitude was a widespread hope that bombarding hydrogen with protons and neutrons of energies up to a few thousand million electron volts would provide a complete understanding of nuclear forces. Thus the field of high energy physics flourished with man-made fast projectiles joining cosmic rays as tools.

However the world of minuscule particles is much more complicated than imagined. It turned out that elementary particles appear in large families, that nucleons exist in excited states, that they have structure and internal degrees of freedom.

In the picture of nuclei composed of nucleons these degrees of freedom are neglected This is a parallel to the fact that when discussing molecules the internal degrees of freedom of the nuclei are usually neglected My question is really a query into the limit of accuracy to which it is permissible to disregard the mesonic or quark degrees of freedom. Last year the School of Nuclear Physics held at the Ettore Majorana Centre of Scientific Culture at Erice, Sicily, and directed by Denys Wilkinson, was exclusively devoted to this question.

The exotic degree of freedom called strangeness (the characteristic quantum number of kaons and hyperons) has been clearly identified in nuclear matter, forming the field of study of hypernuclear spectroscopy. How soon before we see charming nuclear spectroscopy? Thus there exists some knowledge of the level at which the effects appear. Similarly, excited nucleons (with strangeness zero), the so-called N*'s, have been considered in nuclear matter in the same way as they are considered in hadron–nucleon collisions, that is, as resonances, but now broadened by Doppler motion. But my question should really be reformulated: when N*'s, hyperons and so on are produced on nuclei is a nucleus then seen as a collection of quasifree nucleons, or can the effects of the nucleon binding, of the collective of particles forming the nucleus, and of the presence of pions during those exchanges that are responsible for the nuclear forces be discerned? Formulated in this way, it is evident that we ask questions which must be answered by the selection of rare situations or by very high precision. So far, the general feeling is that we have not succeeded in finding the answers. There has been a puzzling result, however.

Collisions between fast nucleons take times T_R of the order of R/c, with R being the nucleon radius in question and c the velocity of light, whereas experiments with fast projectiles take times T_L of the order L/c, where L is the length of our apparatus; the ratio of these time-scales is $T_R/T_L \simeq R/L \simeq 10^{-14}$ to 10^{-17}. Thus what is seen is something that has been fully developed in the apparatus, but may have very different aspects over periods of time that are but a few times T_R. Here the nuclei may be used as detectors enabling observations over nuclear distances R_N in the range $R < R_N < 6 \cdot R$ to be made Developments in ordinary material extending over metre distances can be called 'macroscopic' and developments over nuclear dimensions and with nuclear densities 'microscopic'. The three main results may be summarised as follows (see for example Cronin *et al. 1976 Tbilisi Conference on High Energy Physics*).

Macroscopically, cascades of particles produced near the forward direction are found, that is the incoming hadron produces fast particles, which in turn produce fast particles and so on; microscopically, no such cascading results.

If the final state is a 3π or a 5π state, that is three pions produced or five pions produced, then macroscopically the chance of collision (the cross section) is respectively three times and five times that of a single pion; microscopically, the cross section is very closely equal to that for one pion in both cases.

When very large momenta are carried over in the collision (that is, when the struck particle gains a large amount of energy), a relatively rare event has occurred. Naively, it would be expected that the chance of such events occurring in nuclear matter would grow with nuclear mass number as the nuclear cross section, that is roughly proportional to $A^{2/3}$. Experimentally, the result is proportional to $A^{4/3}$.

These three main results need explanation and further study both experimentally and theoretically. It is not known whether they are nuclear or hadronic effects.

All this does not answer the central question: how many degrees of freedom should we consider in nuclear matter? And when are we to talk about a finite number of constituents and when about continuum? These problems are also linked to the next major point.

Are shock waves observed in nuclear matter?

Certain authors maintain that they have seen such waves but for me the interpretation is not clear. First, I have

Variable DNA repeat lengths

from Rosalind Cotter

AFTER the revelation of the chromatin beaded structure there followed much tangled discussion about the amount, if any, of string between the beads, which was based chiefly on the different unit sizes generated by micrococcal nuclease in Oregon and Cambridge. The argument has now moved from the level of technical disagreements involving digestion termination conditions or faulty calibration to a careful comparison of DNA repeat size in different types of chromatin. A correlation with genetic activity is beginning to emerge.

Chambon and coworkers have examined the DNA repeat length of subunits in chromatin from higher eukaryotes (*Proc. natn. Acad. Sci. U.S.A.* **73**, 4382; 1976). Cells of mature tissues have nucleosomes containing 196 base pairs of DNA, genetically dormant cells rather more, and cells from actively dividing tissues rather less. It has been suggested that smaller DNA repeat lengths are found in primitive eukaryotes, the value for yeast being about 165 base pairs (Thomas & Furber *FEBS Lett.* **66**, 274; 1976), for *Aspergillus nidulans* 154 base pairs (Morris *Cell* **8**, 357; 1976), while 170 base pairs are found in nucleosomes of *Neurospora crassa* (Noll *Cell* **8**, 349; 1976).

These and more recent studies (Lohr *et al. Proc. natn. Acad. Sci U.S.A.* **74**, 79; 1977) have shown that, at early times of digestion with micrococcal nuclease, the most resistant portion of the repeating unit always has 140 base pairs. These core particles, formerly known as monomers, do not vary among species or from tissue to tissue (Morris *Cell* **9**, 627; 1976) with respect to size, histone content (two each of H2A, H2B, H3 and H4), and internal cleavage pattern by DNase I. The variations in repeat lengths are therefore attributable to the more nuclease-sensitive DNA spacer between core particles.

Lohr *et al.* observe a distribution of repeat sizes for yeast and HeLa chromatin, ranging from 140 (that is, no spacer) to 165 base pairs in yeast, to 190 base pairs in HeLa. Chicken erythrocyte oligomers however quickly reach constant sizes during digestion which are compatible with a regular array of core particles and 60 base-pair linkers. The authors speculate on a possible correlation between spacing mode and gene activity, which would be expected to be more complex along chromatin from active cells with sizeable transcribed and non-transcribed regions, and more regular in inactive chromatin in order to meet packaging requirements more efficiently.

The Cambridge group suggest that variations in spacer length may be brought about by histone H1. H1 is highly basic and is thought to interact with phosphates of DNA in the spacer regions. H1 from *Aspergillus* has fewer basic residues than *Neurospora* H1, and can therefore presumably protect only a shorter piece of interbead DNA. Morris notes a subunit repeat for chicken erythrocyte chromatin which is longer than that of chicken liver chromatin, and might be attributable to the partial substitution in the former of H1 by the more basic H5. He discusses the interesting possibility that specific recognition sites such as promoters might have altered accessibilities depending on whether they are incorporated into nucleosome cores or spacers; if then nucleosomes are phased with respect to recognition signals, this phasing could be altered by different H1-like proteins inducing changes in linker length. H1 is known to vary during development and cell differentiation and may therefore influence the accessibility of recognition sites in active chromatin.

no clear picture of what is understood by ordinary sound waves and the velocity of sound in nuclear matter. Bohr and Mottelson (*op cit.*) point out that in nuclear matter one must assume that one deals with zero sound, that is, vibrations that are close to collision-free. If this is the case, then the velocity of sound is likely to be relatively high and shock waves may need even more violent initiation than could first be imagined. To me, the domain is far from exploited and merits much further study both conceptually, theoretically and experimentally.

In addition to the questions raised above, much work needs to be done on nuclei far from stability, including heavy elements and the possible super-heavies. Exotic atoms also present an interesting field; with antimatter available, they can even be envisaged as A_1–$\bar{A}_2$ atoms with strong interaction complications.

All this is, of course, mainly academic. The practical nucleus remains. For the time being however, nuclear applications have become "despised and rejected of men". □

Acid proteases come of age

from Jordan Tang

In the past 10 years, research into the structure and function of proteases has been successful. The exception has been in the area of the acid proteases which has had the status of a stepchild—mainly because of the absence of structural information. But it now seems that the acid proteases have come of age.

Last November, at the 'Conference on Acid Proteases: Structure, Function, and Biology', held at the University of Oklahoma, three new high-resolution crystal structures of microbial acid proteases were reported. The amino acid sequences of two gastric carboxyl proteases, pepsin and chymosin (B. Foltmann, unpublished data) were completed, and a microbial enzyme, penicillopepsin, is near completion These results have provided a new framework for the study of the catalytic mechanism and the evolution of this group of enzymes. (The proceedings of the Conference will be published as a book in the autumn of 1977).

Among this group, the best combination of X-ray and sequence data is in the acid protease from *Penicillium janthinellum*· penicillopepsin This collaborative work of two Canadian groups is reported in this issue of *Nature* (Hsu *et al.* page 140) The enzyme is bilobal and has a pronounced cleft between the two lobes. The 2.8 Å resolution electron density map was calculated, using eight heavy-atom derivatives Although the amino acid sequence of this enzyme is not completed, the sequence of 16 fragments can be aligned against the known sequence of porcine pepsin (Tang *et al.*, *Proc. natn Acad. Sci. U S A* **70**, 3437, 1973). From this alignment, the polypeptide backbone and the side-chains of 326 residues can be traced in the electron density map with little ambiguity. The crystallographic data of acid proteases from two other moulds give essentially the same secondary and tertiary structures. The enzyme from *Rhizopus chinensis* has been solved at 3 Å resolution by D. R. Davies's group at the US National Institutes of Health and the enzyme from *Endothia parasitica* has been solved at the same resolution by T. L. Blundell and coworkers at the University of Sussex. Although little sequence information is available for these two enzymes, the tracings of the polypeptide chains are quite certain The folding of the chains are the same in all three enzymes and the secondary structures consist of large numbers of β-sheets with only a few isolated helical turns. The apparent binding clefts are also extremely similar In all three cases, the clefts extend across the surface of the molecules and are sufficient to accommodate the binding of about 8 amino acid residues of the substrate as suggested from the specificity studies of microbial acid proteases and pepsin

A close relationship of tertiary structures of porcine pepsin and the microbial acid proteases is indicated by sequence homology. As mentioned above, the fragments of penicillopepsin can be aligned against the pepsin sequence. Computer programmed comparison shows 11 highly conserved regions, including the regions near the catalytic aspartyl residues which will be discussed below The crystal structure of porcine pepsin is still uncertain. The previously reported 2.7 Å resolution structure (Andreeva *et al. Dokl Akad. Nauk U.S.S.R.* **228**, 480; 1976) shows a considerable number of contacts along the molecular boundary; a revision of the molecular boundary, as well as a new interpretation of this map, is underway. However, a comparison of the tertiary structures of pepsin and the acid protease from *R. chinensis* by Andreeva (unpublished results), using the data of Davies with the calculation of rotation function, indicates a high degree of similarity—confirming the implication of sequence comparison.

There has never been any doubt that the active centres of all the acid proteases are very much alike. Two active centre aspartyl residues, 32 and 215 in pepsin were identified by means of active site directed modifying reagents—an epoxide and a diazo compound. These reagents also inactivate most of the other acid proteases. In the crystal structure of all three microbial acid proteases, these aspartyl residues are found to be close to each other at the centre of the apparent binding cleft. In the case of penicillopepsin, the chains of Asp-32 and Asp-215 are in intimate contact so that, as suggested by Hsu *et al.*, they may share a common proton between the oxygen atoms of the two aspartyl residues. In addition, Ser-35 is hydrogen bonded to the other carboxyl oxygen of Asp-32. These three hydrogen-bonded residues. Ser-35, Asp-32, Asp-215, are reminiscent of the charge relay system of the serine protease All three residues are also conserved in the known sequences of acid proteases. The hydrogen bondings could easily explain the low *p*Ka of Asp-32 (~ 2) and the slightly high *p*Ka of Asp-215 (~ 4.5).

But, despite these new findings, the detailed catalytic mechanism of acid proteases is unlikely to be solved quickly. First, direct evidence on the position and orientation of substrates or products in the crystals, which undoubtedly will be studied soon, has not been obtained. The possible roles of some groups near the catalytic site (for example Thr-216 and Gly-217) are also uncertain. Second, although the suggestion of the catalytic roles of two aspartyl residues can easily be fitted to the crystal structures, this evidence does not exclude any of the previously proposed mechanisms based on the catalysis by two carboxyl groups. For example, the controversy regarding the presence of an enzyme–amide intermediate in the catalysis of acid proteases is still unsettled.

The binding position of pepstatin, a strong inhibitor for all acid proteases ($K=10^{-10}$ M for pepsin), has been determined at low resolution in the crystal structure of the *R. chinensis* enzyme (Subramenian *et al. Biochem. biophys. Res. Commun.* **68**, 875; 1975). This hexapeptide binds as an extended chain in the centre of the apparent substrate binding cleft. This finding agrees with the results of kinetic studies, using pepstatin fragments, which suggest that pepstatin is a transition state analogue of peptic hydrolysis (Marciniszyn *et al. J. biol.*

Chem. **251**, 7088; 1976).

The mystery of the mechanism by which the active centre is involved in the intramolecular activation of the zymogens of acid proteases seems to have been intensified by the knowledge of the tertiary structures. No zymogen has been found for the microbial acid proteases, but based on sequence comparison the NH_2-terminal position aligns closely in the linear structure with that of pepsin. Assuming that the NH_2-terminal chain in pepsin is positioned in its tertiary structure like those chains found in three microbial enzymes, then this polypeptide chain would be extended away from the active centre with the NH_2-terminus on the other side of the molecule away from the binding cleft. However, kinetic data indicate that the intramolecular activation of pepsinogen is inhibited by pepstatin and 'competitively' inhibited by a protein substrate (Marciniszyn *et al*, *J. biol. Chem.* **251**, 7095; 1976). This suggests that pepsin's active centre is involved in the intramolecular activation of pepsinogen. The manner by which this is accomplished in the zymogen molecule is unclear.

The results of the crystallographic and sequence studies undoubtedly will serve as models in the study of a large group of acid proteases in various biological systems. These include chymosin, the lysosomal cathepsin D and E, renin, acid proteases in blood and seminal plasma, and others It is now clear that the microbial and gastric acid proteases are derived by divergent evolution from a common ancestral gene. Cathepsin D and renin, which are similar in size to pepsin, may fall into the same evolutionary pattern. If so, then the reason that renin is derived from an acid protease in evolution might be to take advantage of the extended binding cleft. The stringent specificity requirement of eight residues in the substrate of renin thus can be accommodated These structural developments mark the beginning of more fruitful investigation into structure–function relations of the acid proteases. □

Eukaryotic chromosome structure

by Eleanor Lawrence

A Royal Society meeting on the Structure of Eukaryotic Chromosomes and Chromatin organised by Professor H. G. Callan and Dr A. Klug, was held in London on 16 and 17 February, 1977.

THE meeting covered various aspects of chromosome structure and function ranging from the fine structure of chromatin to the morphology of transcriptional units to detailed genetic studies at the molecular level.

At the level of chromatin structure, now that the string of beads model is generally accepted, attention is focused on the detailed structure of the nucleosome on the one hand and chromatin superstructure on the other. The role of 'histone' H1 in stabilising chromatin superstructure was brought out by several speakers. Although it does not seem necessary for maintaining the integrity of the nucleosome itself it seems to be essential for maintaining internucleosome connections.

P. Chambon (University of Strasbourg) described experiments which show that although all four histones H3, H4, H2A and H2B are required to assemble a complete nucleosome, H3 and H4 alone with SV40 DNA will produce small beaded structures of 75±10 Å and introduce the characteristic superhelical turns into the DNA.

The physical requirements of DNA replication and transcription have led to the proposal that the nucleosome should perhaps be able to split apart in some way, allowing free movement and replication of the DNA without completely shedding the histone. This feature has been built into current models (see for example Weintraub *et al. Cell* **9**, 409; 1976) and Chambon reported that at very low ionic strength, 'half-nucleosomes' of 90 Å diameter can be seen in the electron microscope.

At low ionic strengths A. J. Varshavsky (Institute of Molecular Biology) has obtained three types of nucleosomal particle — MN1 which appears to be the 'core' particle, MN2 which contains 170 bp DNA and has one H1 molecule associated with each particle and MN3, 200 bp and two H1 molecules per particle. He has also found an array of subnucleosomal particles ranging from 20 bp DNA lengths with no histones attached to particles containing 120 bp and all four histones, but as yet it is not possible to interpret these various subnucleosomal particles in terms of nucleosomal structure.

Biochemical studies on chromatin were reported by H. G. Zachau (University of Munich) who finds that at high salt conditions, or in the presence of divalent cations (Mg^{2+}, Ca^{2+}) DNase II produces 100 bp repeats from chromatin rather than the normal 200 bp repeats This is interpreted as a cleavage site's becoming available within the nucleosome in certain conditions. The integrity of the nucleosome is not destroyed even though the DNA is cut. Calf thymus chromatin depleted of H1 however, showed no 100 bp repeats which only reappeared when H1 was readded and Ca^{2+} was present, showing that a certain amount of superstructure is necessary for generation of the 100 bp fragments.

The structure of native chromosomes is even more difficult to probe however. A. Worcel (Princeton University) reported the finding of supercoiled loops of DNA of around 400 nucleosomes per loop in genomes of interphase nuclei of cultured *Drosophila* cells isolated in 0.9 M HCl which removes H1. In the electron microscope a very gently prepared whole genome shows a nucleofilament of 100 Å thick with no signs of a beaded structure. Worcel identifies this nucleofilament as the supercoiled thread. DNase I treatment of this preparation appears to partly release the supercoils and produce the beaded string appearance. Worcel suggested that the removal of H1 *in vivo* might be involved in the formation of transcriptionally active chromosome puffs.

R. L. Kornberg (Havard Medical School) produced evidence that nucleosome formation is random with respect to DNA sequence. If the 140 bp core DNA fragments produced from different copies of the same stretch of chromatin are always the same, single-stranded copies of opposite halves of the set of 140 bp fragments produced by digestion with exonuclease III (which digests DNA from the 3′ ends only) should not reassociate. If they carry certain sequences in common, as predicted if nucleosome formation is random with respect to DNA sequence there will be reassociation, and for single-copy DNA sequences from rat liver chromatin, Kornberg's evidence seems to show the latter to be the case He has also found variable internucleosome lengths in chromatin from the same cell type, results consonant with the finding that nucleosome formation is random.

The use of recombinant DNA techniques has revolutionised the study of gene organisation and sequence. By cloning fragments of the *Drosophila* genome and then mapping the cloned fragments back on to the polytene chromosomes D. Hogness (Stanford University) has identified various families of repeated sequences, some, like the histone genes, tandemly repeated, others, as yet functionally unidentified, dispersed throughout the genome. The histone gene repeat unit contains the five histone genes but unlike those in the sea urchin (reported by M. Birnstiel, University of Zurich), H1, H3 and H2A are transcribed off one strand and H4 and H2B off the other. A repeated sequence is found between H3 and H4 and between H2A and H2B and may possibly contain a bidirectional promoter. Tandemly repeated genes appear to be commonly regulated—all on or all off. Dispersed repeated genes on the other hand are apparently regulated independently and different ones may be turned on in different cell types or at different stages in differentiation. Sequencing of two of the dispersed families shows them to have repeated sequences of 500 bp at either end.

M. Birnstiel described continuing sequence studies on the histone gene repeat unit isolated from the sea urchin *Psammechinus miliaris*. About 25% of the total repeat unit comprising the five histone genes separated by spacer DNA has now been sequenced. The structural gene sequences agree well with those predicted on the basis of amino acid sequence, with minor differences attributable to the source of histone. Parts of the spacers which have been sequenced show no repeated sequences The *Hin*dIII spacer at the end of the unit is full of stop codons so is presumably non-coding. Some (presumably non-functional) initiation sequences have also been identified in this region. Spacer regions close to the 5′ ends of H1 and H2A show some very non-random conserved base pairs just in front of the Met initiation site. These are presumably ribosome-binding sites but this is not yet certain since they do not resemble the ribosome-binding sites identified on brome mosaic virus.

The next step would be to delete various regions of the unit and see how this affects function. A possible assay system might be that described by John Gurdon (MRC Laboratory of Molecular Biology, Cambridge) in which DNA fragments injected into the nuclei of *Xenopus* oocytes have been shown to be accurately transcribed and in some cases translated.

Transcription of the human histone genes is also being studied in Birnstiel's laboratory. The human repeat unit is found in a stretch of 14 5 kb which if transcribed together would give a polycistronic message of 50S. Such a message has been found in HeLa cells and appears to be processed to a 9S message in the cytoplasm via 17S and 28S molecules. Control of histone gene expression also appears to be post-transcriptional since G2 phase cells (when no new histones appear) still transcribe messenger.

Another approach to the study of control of gene expression is to look at the organisation of the actively transcribing regions on spread chromatin. C. D Laird (University of Washington, Seattle) described studies defining transcriptional units on *Drosophila* chromosomes. Analysis of patterns of ribonucleoprotein (RND) fibre lengths along sparsely-fibred regions of actively transcribing non-ribosomal chromatin suggest specific initiation and termination sites for each transcriptional unit. Discontinuous patterns of RNP fibre length along the transcriptional unit have been seen suggesting perhaps that the RNP fibres have been partially cleaved at some point before transcription is terminated. Contiguous transcription units have been found in embryonic *Drosophila* cells

The problem of whether the characteristic beaded structure for chromatin is maintained in actively transcribing regions is still not completely resolved, but the weight of evidence now tends to the view that it is not (W. W. Francke, German Cancer Research Centre, Heidelberg; Laird). □

Reactions with excited alpha particles: ^{12}C (α, α*)

from P. E. Hodgson

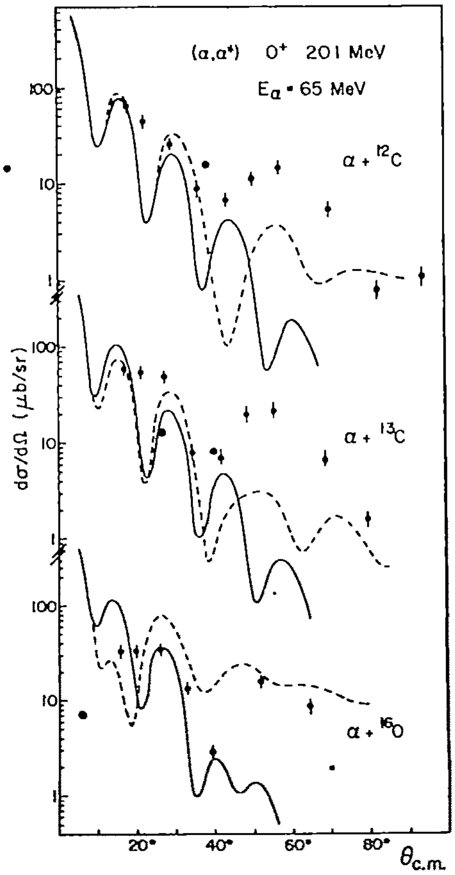
THERE is now a growing interest in using nuclear reactions with unstable emitted particles in studies of nuclear structure. Among the possible reactions, those leading to the emission of ^{8}Be are the easiest to use, because the ^{8}Be decays rapidly into two alpha particles that can be detected in coincidence. Another practicable reaction of this type is the (α, ^{2}He) reaction, where the unstable ^{2}He nucleus is detected by the coincidence of the protons into which it decays (*Nature* **264**, 511; 1976). Such reactions open up new possibilities for nuclear spectroscopy, so it is useful to see whether there are any more unstable particles that can be detected in a similar way.

One of the possibilities that has been recently realised is the inelastic scattering of alpha particles with the emission in the excited state at 20.1 MeV. This is an unbound monopole 0^+ state with a width of 0.27 MeV. An alpha particle in this state readily decays into a proton and a triton, and since the energy release is only 0.3 MeV the decay products are emitted in almost the same direction and so can easily be detected by coincidence techniques.

This reaction has recently been observed by Jahn and colleagues (*Phys. Rev. Lett.* **65B**, 339; 1976). They irradiated targets of ^{12}C, ^{13}C and ^{16}O with 65 MeV alpha particles and looked for protons and tritons emitted in coincidence. They found definite evidence that alpha particles are sometimes emitted in the state of monopole excitation, and in the case of the reaction on ^{12}C their energies corresponded to the reactions that leave the residual ^{12}C nucleus in the ground state, in the 2^+ state at 4.44 MeV and in the 3^- state at 9.64 MeV. The cross sections for these reactions are about one-thousandth of those of the corresponding reactions with the emission of alpha particles in their ground state.

Distorted wave calculations were made to see if the observed cross sections could be accounted for by existing theories. The transition matrix elements were calculated microscopically using the particle–hole model and also the collective model. The distorted waves were generated by optical potentials fitted to the elastic scattering of 65 MeV alpha particles.

These calculations agree quite well with the absolute values of the experi-



Differential cross sections for the (α, α*) reaction to the ground states of ^{12}C, ^{13}C and ^{16}O compared with distorted wave calculations using transition densities obtained from the particle–hole (solid curves) and collective (dashed curves) models.

mental cross sections, but not very well with the details of the angular distributions, as shown in the figure. This discrepancy may indicate the importance of higher order effects, in particular the two-step reactions that proceed through an intermediate state.

The detection of this reaction opens up a new area of nuclear reaction and nuclear structure studies, and in particular suggests that it may be useful to look for the (^{3}He, α^*) and (d, α^*) reactions as well. ☐

Tertiary plate motions

from Peter J. Smith

THE relative angular velocities of the Earth's lithospheric plates are now quite well known. The 'absolute' angular velocities of the plates (that is their velocities relative to the mesosphere) are known much less precisely; but if one accepts, with Solomon *et al.* (*Geophys. J.* **42**, 766; 1975), that absolute linear velocities can now be specified to within 1–2 cm yr^{-1}, then it is possible to make three statements, or groups of statements, about their relationships. First, there is a good, but not perfect, general correlation between the velocity of a plate and the fraction of the plate occupied by continent; the greater the proportion of continent the lower is the velocity. At the extremes, predominantly oceanic plates have velocities in the range 7–10 cm yr^{-1} whereas predominantly continental plates generally move at 0–2 cm yr^{-1}. Second, plates being subducted along a major proportion of their boundaries all have high velocities. And third, lithosphere in the equatorial half of the Earth has a higher r.m.s. velocity that that in the two polar quarters.

These three statements give rise, in turn, to three questions. Do continental plates move more slowly because there is a greater viscous drag at the base of the continental lithosphere than beneath the oceanic lithosphere? Do subducting plates have high velocities because of a major force exerted by the downgoing lithospheric slabs? And does the polar–equatorial velocity differential arise because of a connection between plate motions and the Earth's rotation? It is tempting to allow circumstantial evidence to answer all three questions in the affirmative, or at the very least to argue that the relationships indicated by the three statements have underlying physical causes. But equally, such relationships could well be coincidental. How, then, can the issue be decided?

The ideal way, as Solomon *et al.* (*J. geophys. Res.* **82**, 203; 1977) point out, would be "to observe a number of global plate systems, each with very different plate geometries but obeying similar physical laws". But that is obviously not possible; so Solomon and his colleagues have done the next best thing in studying the behaviour of the Earth's plates as they were arranged 55 Myr ago. Using the plate boundary map for that period already constructed by Jurdy and Van der Voo (*J. geophys. Res.* **79**, 2945; 1974) together with published values for finite plate rotations, they first determined the relative plate velocities. Absolute velocities were then calculated, assuming no net torque to be exerted on the lithosphere for a series of models having driving forces symmetrical about the plate boundaries and a plate-retarding viscous drag at the base of the lithosphere.

Needless to say, such determinations are more complicated that they are made to sound here and involve numerous assumptions, approximations and simplifications that may later give critics cause to make trouble Taken at face value, however, the results suggest that it may be dangerous to invoke particular physical processes purely on the basis of the behaviour of the plates as they are arranged now. For one thing, with the plates as they were 55 Myr ago there is apparently no correlation between r.m.s. absolute linear velocity and the fraction of the plate comprising continent, assuming the viscous drag to be uniform at the base of both the continental and oceanic lithospheres. Nor is there a clear division between fast-moving predominantly oceanic plates and slow-moving predominantly continental plates. For example, 55 Myr ago the Eurasian plate, 93% of which is continent, had a velocity about equal to that of the Pacific plate. It is true that the Eurasian plate is much slowed down if the uniform drag model is replaced by one in which there is drag only beneath the continental lithosphere; but not only would the latter model violate palaeomagnetic and other constraints, it would actually produce an increase in most continental velocities.

Fifty-five million years ago, plates with major subduction zones were not all moving rapidly either. The Farallon plate, for example, with a large fraction of its boundary under active subduction, was moving at less than half of the rate of the fastest (Kula) plate. On the other hand, the conclusion to be drawn from the polar–equatorial velocity differential is more ambiguous. The differential undoubtedly existed, albeit in a much weaker form than at present. But whereas the coordinate pole giving the maximum equatorial r.m.s. velocity is now almost coincident with the geographic pole (apparently strengthening the supposition that plate motions and the Earth's rotation are linked), it is 60° from the geographic pole for the older plate distribution. Solomon and his colleagues therefore conclude that the case for a relationship between the Earth's rotation and plate velocities is "not particularly compelling" at 55 Myr and thus, by implication, at present.

On balance, then, this new evidence suggests that the three original questions should be answered negatively; and the fact that affirmative answers are consistent with current plate motions would appear to be a coincidence. But that is not all, for Solomon *et al.* have also been able to bring their analysis to bear on the controversy over whether or not the supposed mantle plumes from which hot spots are derived are fixed in the mantle. By comparing their newly-determined absolute plate motions with observed hot spot traces, they find the fits between azimuths to be variable. For hot spot traces within the Indian and African plates the fits are within expected errors, but there are serious misfits for Pacific plate hot spots and the Icelandic hot spot. In short, not all mantle plumes appear to be fixed with respect to each other and thus not all can be fixed with respect to the mantle. ☐

A hundred years ago

HIS Majesty, the Emperor of Brazil, observed the eclipse of the moon on the evening of the 27th, at the Arcetri Observatory. The Emperor took a very lively interest in the phenomenon and discussed with acuteness the hypothesis with which Prof. Tempel, the astronomer, and Prof. Echert tried to explain the varying shades and colours in which the moon appeared during the different phases of obscuration. On Monday last his Majesty assisted at a meeting of the Anthropological Society, when Prof. Mantegazza made some interesting remarks on several Maori skulls, and Prof. Giglioli read an elaborate paper on the ethnology of Brazil.

Binary X-ray pulsars

S. Rappaport & P. C. Joss

Department of Physics and Center for Space Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

There are nine known X-ray pulsars, which are widely believed to be rotating magnetised neutron stars that are accreting matter from their binary stellar companions. The observed pulse profiles provide information on the physics of the accretion process. We present representative profiles of all nine sources for comparison of general features, and we discuss some of these features in terms of the accreting neutron-star model.

THERE are about 150 known galactic X-ray sources. The most widely accepted model, for those sources not associated with supernova remnants, involves a compact object (white dwarf, neutron star, or black hole) in orbit about a relatively normal stellar companion[1]. The energy source for X-ray emission by the compact object is derived from the accretion of matter that is supplied by either a stellar wind or critical-lobe overflow from the companion[2-5]. During the first systematic X-ray sky survey with the Uhuru satellite[6], two of these sources were discovered to be regularly pulsing: Centaurus X-3 (ref. 7) (pulse period $P = 4.8$ s) and Hercules X-1 (ref. 8) ($P = 1.2$ s). Evidence for slow pulsation ($P \simeq 2$ min) in another source, GX1+4, had previously been obtained from a balloon observation[33]. For the X-ray pulsars, it seems very probable that the accreting compact objects are rotating magnetised neutron stars (see, for example, ref. 9 and references therein).

The Uhuru satellite was most sensitive to X-ray pulsations in the period range 0.2–10 s. During the past two years at least six other X-ray pulsars have been discovered. The study of X-ray pulsars has been greatly advanced by the Copernicus, Ariel V, and SAS-3 satellites. Table 1 lists the confirmed X-ray pulsars and, where known, the optical companion. The Crab Nebula pulsar, NP0532, is not included because it is evidently not in a binary system and because its pulsar mechanism is distinctly different from that of the binary X-ray pulsars.

Binary X-ray pulsars as an astrophysical tool

Binary X-ray pulsars provide at least three powerful sources of astrophysical information. First, the rotating neutron star acts as an orbiting clock that enables the observer to measure Doppler effects and thereby determine the size and shape of the orbit about the companion star. This orbital information, coupled with other supplemental data, enables one to place constraints on the masses of both the neutron star and its companion star[9] and on the size of the companion (see, for example, ref. 48). These quantities are of interest in a wide range of studies from nuclear physics to stellar evolution. Second, information on secular changes in the intrinsic pulse period can help in the understanding of the accretion process near the Alfvén surface (radius ~ 3×10^8 cm (refs 2–5)) that surrounds the neutron star. It is at this surface that the dynamics of the accreting matter are first dominated by the intense magnetic field associated with the neutron star and where the spinup or spindown torque on the neutron star is effectively applied. Third, a study of the intensity profiles of the X-ray pulsations may reveal details of the final stages of accretion onto the surface of the neutron star (radius ~ 10^6 cm). The pulse profiles may also be a direct measure of the transmission of the radiation, produced near the surface of the neutron star, through the infalling plasma. Here we discuss recent progress in the study of the pulse profiles of X-ray pulsars.

Pulse profiles

Sample X-ray pulse profiles for the nine binary X-ray pulsars listed in Table 1 are shown in Fig. 1. In all cases, the pulse profiles were obtained by integrating over ~ 10^2 to ~ 10^4 individual pulses. For several of the pulsars, the pulse profiles do not change significantly with energy over the range 2–10 keV. For others (for example, A0535+26 (ref. 29) and 3U0900−40 (ref. 39) the dependence on energy is so strong that we display data for one arbitrary narrow energy range only. It now appears that for many of the pulsars, the basic pulse profiles and their energy dependence are preserved over a time scale of at least a year. (The highly variable pulse profiles of GX1+4 seem to be an exception (refs 35 and 67). On the other hand, certain details, such as a strong secondary peak in Her X-1 (Fig. 1), are seen only on occasion.

The profiles in Fig. 1 display a wide range of complexity, ranging from single smooth intensity maxima to five maxima with additional substructure per pulse period. What general features do these profiles exhibit? (1) The profiles are all characterised by large 'duty cycles' that are in the range ~ 30–100%. This is an order of magnitude larger than those of the narrow pulses observed for radio pulsars[49]. (2) The modulation factors [defined as (maximum intensity minus minimum intensity)/maximum intensity] all fall in the range ~ 0.5–0.9. (3) At least three of the profiles exhibit sharp features. (We define such a feature as a substantial change in intensity in less than ~ 5% of a pulse period.) (4) The degree of symmetry of the pulse profiles varies widely from the nearly symmetric shapes of GX301−2 and A1118−61, which contain two times of mirror symmetry per pulse, to the asymmetric shapes of A0535+26 and 3U0900−40 that contain no symmetry times. (5) There is no significant trend in the complexity of the profiles as a function of pulse period. For example, the pulse profiles of SMC X-1 and GX301−2 are somewhat similar in form, as are those of Her X-1 and 3U0900+40. (6) There is a tendency for the profiles of some of the slow pulsars (for example, A0535+26 and 3U0900−40) to vary greatly with energy; at higher energies (not shown in Fig. 1), these pulse profiles become simpler than in the 1–10-keV range.

We note, as have other workers, the apparent existence of a gap in the period distribution of X-ray pulsars, ranging from P ~ 5 s to P ~ 100 s. As of this writing, the gap seems to be genuine within the obvious statistical limits and is probably not an observational effect.

Pulsation mechanisms

The most widely accepted mechanism for producing pulsed X-ray emission invokes the chanelling of accreted matter to the surface of a rotating neutron star by intense magnetic fields (~ 10^{12}–10^{13} G (refs 2–5)). For all of the X-ray pulsars, the pulse profiles are probably determined by the following parameters: the mass accretion rate; the magnetic field configuration near the surface (that is, dipole field or fields of higher complexity); the relative angles between the rotation axis, magnetic axis, accretion disk (if any), and the observer; and the rotation period. Aside from obviously determining the pulse period, the rotation period probably influences the manner in which the accretion across the Alfvén surface occurs[50].

These considerations suggest two explanations for the production of X-ray pulsations. The first requires a temporal modulation of the accretion of matter onto the surface of the neutron star (ref. 51 and M. Rees, personal communication). This might occur if the accreting material originates in a stellar wind from the companion star, passes through a shock front near the neutron star, and accretes without the formation of an accretion disk (see, for example, S. L. Shapiro and A. P. Lightman, preprint). The accretion may then take place at a variable rate that depends upon the instantaneous angle between the magnetic axis and the direction of the stellar wind. A temporal modulation of accreted material could also occur if an accretion disk surrounds the neutron star and the rotation axis of the neutron star is not perpendicular to the disk. A non-aligned magnetic axis would then cause the accretion disk to pass through different magnetic latitudes as a function of time[51]. In either of these cases the pulse profiles would represent, at least in part, the modulation of the rate of matter reaching the surface. The former case, however, predicts an orbital-phase dependence for the pulse profiles (M. Rees, personal communication) that has not been observed to date (unpublished SAS-3 data). In the latter case, the explanation probably fails at least for Her X-1 (which is widely believed to accrete from a disk), where pulse structure has been observed on a time scale of ~ 20 ms (Fig. 1). Since the free-fall time from the Alfvén surface is ~ 0.2 s, it is doubtful that significantly smaller time structure can result from temporal modulation of the accretion rate.

Table 1 Binary X-ray pulsars

Source	Pulse period (s)	References			Optical companion

* Transient source.

† Confirmation of the presence of pulsation was obtained by White *et al* [34].

An alternative and more likely picture[3–5,52–57] for producing the pulsations requires the funnelling of matter along the magnetic field lines to the surface of the neutron star, where the released gravitational potential energy heats a small area on the surface (~ 1 km^2) to extremely high temperatures ($\gtrsim 10^8$ K). The radiation from each of the magnetic polar caps distribution that reflects both the location of the surface hotspots (there may be more than two) might be approximately isotropic or it might be beamed by a cyclotron emission process[52]. In either case, the emergent radiation must then pass through and interact with the infalling magnetised plasma (see, for example, refs 52, 55 and 56). Near the bases of the accretion columns, the magnetic field strengths and particle densities may well be as high as ~ 10^{13} G and ~ 10^{22} cm^{-3}, respectively. A variety of photon absorption, emission and scattering processes are possible in these extreme conditions (for example, free-free absorption[58,59], cyclotron processes[50,52,60], and anisotropic Thomson scattering[58,61]), all influenced by the strong magnetic field. With the wide ranges of temperature, density, and magnetic field strength that probably occur within the accreting matter, the radiative transfer problem is exceedingly complicated and has heretofore been quantitatively investigated only for specific scattering mechanisms and in various limiting cases of temperature and magnetic field[52,55,56,62].

After the radiation has diffused through the infalling medium, it should emerge as X radiation and will have an angular distribution that reflects both the location of the surface hotspots and the radiative transfer through the medium (including possible transfer through matter near the Alfvén surface[63,64]). This distribution may, in the first approximation and for the case of a simple dipole field, be a function of magnetic latitude only. For a more complex magnetic-field configuration, the emergent X-ray distribution can depend on magnetic longitude as well as latitude. As the neutron star rotates about its axis (which is presumably not aligned with the magnetic axis), a distant observer will pass over a range of magnetic coordinates and will thereby observe a corresponding X-ray pulse structure. It is immediately evident (Fig. 1) that the complex pulse profiles observed for several sources (for example Her X-1, A0535+26, and 3U0900−40) cannot be only the result of scattering and absorption in accretion columns associated with a simpel dipole field, which would yield profiles with two times of mirror symmetry per pulse.

Conclusions

Of approximately 150 galactic X-ray sources, nine are known to be binary X-ray pulsars. The list is not likely to expand quickly to include many of the remaining sources. Numerous galactic sources have been searched for regular pulsation over a wide range of possible pulse periods with negative results (limits on pulsed fraction of a few percent; unpublished SAS-3 data of S. Rappaport). However, a significant amount of information on the nature of binary X-ray pulsars has already been developed from studies of the nine pulsars discussed in this article. Further observations will probably reveal some new pulsars and these will improve the quality of the statistical information on the properties of these sources. For example, does a genuine gap exist in the pulse period distribution? Are there any systematic trends in the typical pulse profiles as a function of pulse period?

It is possible that the futher study of binary X-ray pulsars will not lead in the forseeable future to any conclusive understanding of the relevant physics and astrophysics involved. This situation may have already emerged in the study of radio pulsars[46]. It might be argued that because binary X-ray pulsars are not isolated objects, their physics may be even more difficult to unravel than that of radio pulsars. It is our belief, however, that while the picture is indeed complex, we already have a sound qualitative idea of the underlying physical processes at work in these systems, and the prospects for further significant advances in our quantitative understanding are therefore encouraging.

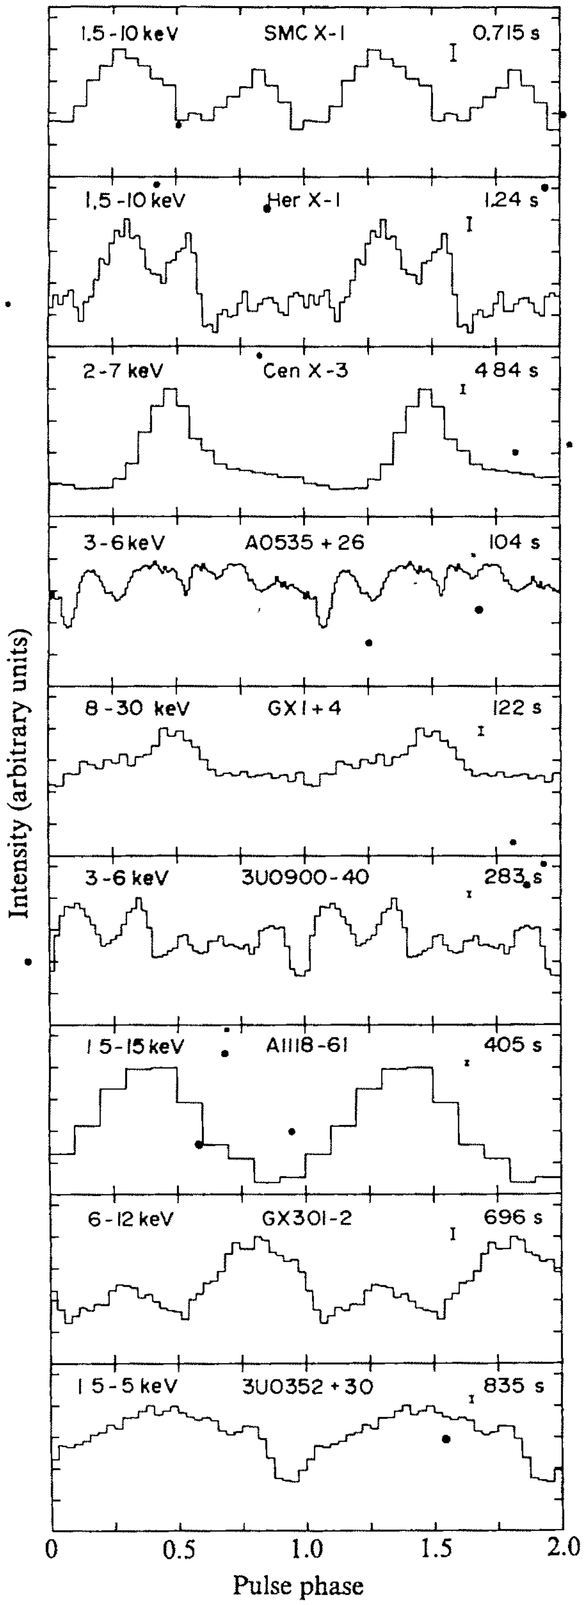

Fig. 1 Pulse profiles for the nine X-ray pulsars that are thought to be in binary systems. In each case, the data (Table 1) are folded modulo the pulse period and plotted against pulse phase for two complete cycles. The approximate pulse periods and energy intervals are indicated for each pulsar. Non-source background counting rates have been subtracted. A typical ±1σ error bar, derived from photon counting statistics, is indicated for each pulse profile.

We are grateful to D. Q. Lamb and F. K. Lamb for a helpful discussion. We thank P. Hertz for assistance in the preparation of Figure 1. This work was supported in part by the US National Aeronautics and Space Administration.

Distances of the Virgo, Fornax and Hydra clusters of galaxies and the local value of the Hubble ratio

G. de Vaucouleurs*

Royal Observatory, Edinburgh, UK

Distances of three nearby clusters of galaxies derived from recent observations of the brightest globular clusters in the brightest galaxies are now in good agreement with other distance indicators and suggest a local value of the Hubble 'constant' $H = 86 \pm 9$ *km* s^{-1} *Mpc*$^{-1}$.

RECENT observations have renewed interest in the concept of the brightest globular star clusters in galaxies as stochastic distance indicators subject to size-of-sample effects[1,2]. The thorough study by Hanes[3] of the apparent magnitudes of the brightest globular clusters in 12 of the brightest galaxies in the Virgo I cluster facilitates a better determination of the cluster population and luminosity function in relation to the luminosity of the parent galaxy. Smith and Weedman[4] reported very faint objects, probably globular clusters, at magnitudes $B \simeq 23$ to 24 and fainter, around NGC 3311, the brightest galaxy in the Hydra I cluster. Dawe and Dickens[5] described faint objects, possibly globular clusters, appearing at magnitudes $B \geqslant 21.0 \pm 0.6$ (m.e.) around several of the brighter galaxies in the Fornax I cluster.

In this paper I first revise the basic parameters, $\bar{M}$(CL) and $\sigma(M)$, the mean and dispersion of the gaussian model used to estimate the expectation value $M_B(1)$ of the brightest globular cluster as a function of the absolute magnitude $M_B{}^*(G)$ of the parent galaxy. Second, I introduce a new version of the brightest cluster method which does not require successive approximations. Third, I derive the absolute distance modulus μ_0 of the Virgo I cluster from $M_B(1)$ in the brightest elliptical and lenticular members. Fourth, I derive the distance modulus difference $\delta\mu_0$ between For I and Vir I from several distance indicators, including the suspected globular clusters. Fifth, I derive an approximate modulus for Hya I from the apparent magnitudes and diameters of its brightest members and from $M_B(1)$ in NGC 3311. Finally, I derive the values of the velocity–distance ratio (Hubble 'constant') in the directions of these three nearby clusters, two of which are well outside the boundaries of the Local Supercluster. The result '$H = 86 \pm 9$ km s^{-1} Mpc^{-1}' is in general agreement with several independent estimates[6–9], but in disagreement with others[10,11].

Luminosity function of globular clusters and expectation value of $M_B(1)$

The luminosity function of galactic globular clusters is very nearly gaussian (Fig. 1). The cumulative frequency function of the absolute magnitudes listed for 105 clusters by Kukarkin (ref. 12, Table F) is well approximated by a Laplace–Gauss integral with mean $\bar{M}(\text{CL}) = -7.2$ and $\sigma(M) = 1.2$ mag (dashed curve). The better-defined brighter half, which is of more immediate interest for the evaluation of $M_B(1)$, is more closely fitted by $M_V(\text{CL}) = -7.3$, $\sigma(M < \bar{M}) = 1.1$ mag (solid curve). The latter parameters are adopted in this article. The distance scale used by Kukarkin is defined by the mean magnitude of the RR Lyrae variables in 89 clusters $\bar{M}_V(\text{RR}) = +0.86$

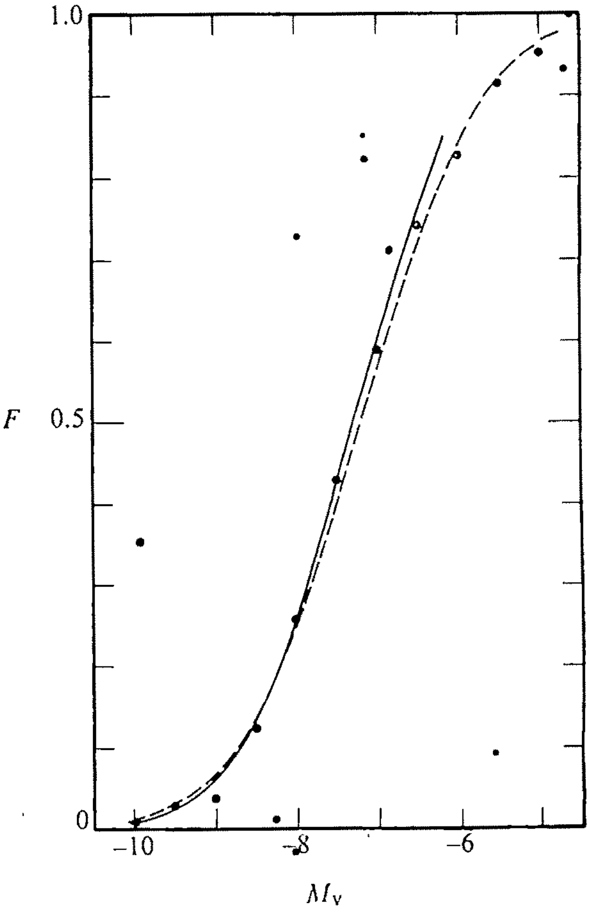

Fig. 1 Cumulative luminosity function $F = N(\text{CL})M_V)/N_T$ of 105 galactic globular clusters from Kukarkin's catalogue. The dashed curve is a Laplace–Gauss integral with mean $\bar{M}_V(\text{CL}) = -7.2$ and dispersion $\sigma(M) = 1.2$ mag; the solid curve with $\bar{M}_V(\text{CL}) \doteq -7.3$, $\sigma(M) = 1.1$ mag gives a better fit of the brighter half of the luminosity function.

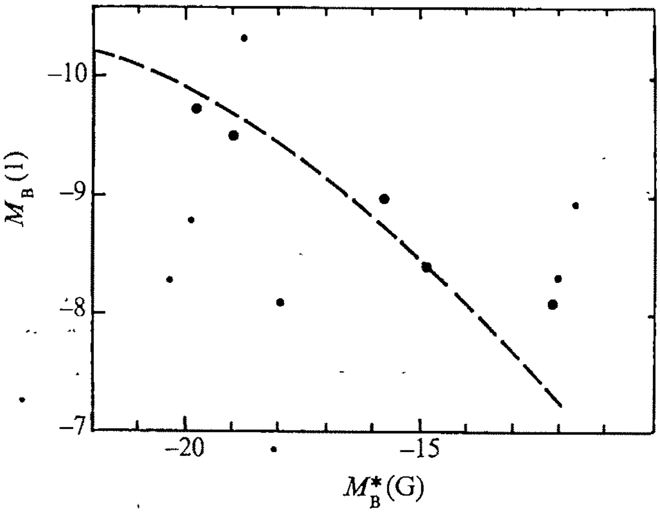

Fig. 2 Observed and computed absolute magnitude $M_B(1)$ of brightest globular cluster as a function of absolute magnitude of spheroidal component of galaxy $M_B^*(G)$. Dashed curve is from statistical theory.

(range 0.57–1.33) (ref. 12 Table 8). A similar fit of the B-band luminosity function gives $\overline{M}_B = -6.55$ and $\sigma(\overline{M}_B < M_B) = 1.1 \pm 0.05$.

The derived expectation value $M_B(1)$ of the brightest cluster depicted in Fig. 2 as a function of $M_B^*(G)$ depends also on the relation between the total cluster population N and $M_B^*(G)$. The adopted relation, $\log N = -0.3\ (M_B^*(G) + 11.0)$, is a corrected average of those used in refs 1 and 2. It is rather uncertain and further studies will be necessary to establish this relation more firmly and to determine whether N depends also on other factors. For the present the main justification of the adopted relation is its agreement with empirical data on B_1(CL) for five galaxies of the Local Group covering at least a 5-magnitude range in $M_B^*(G)$ (Table 1). Except for the Fornax dwarf where statistical fluctuations may be expected because of the very small sample ($N = 5$), the O–C residuals are all within ± 0.25 mag which is well within the errors of the data and approximations of the model.

$M_B(1) - M_B^*(G) = B_1(\mathrm{CL}) - B_T^*(G)$ as distance indicator

Derivation of the distance modulus from Fig. 2 requires in general several successive (but rapidly converging) approximations as explained in ref. 1. The need for successive approximations is eliminated in a variant of the method using the difference of apparent magnitudes between the brightest cluster B_1(CL) and the galaxy $B_T^*(G)$ to calculate directly the absolute magnitude $M_B^*(G)$ and apparent distance modulus $\mu = B_T^*(G) - M_B^*(G)$ of the galaxy. Figure 3 shows the relationship between $M_B^*(G)$ and $M_B(1) - M_B^*(G) = B_1(\mathrm{CL}) - B_T^*(G)$ derived from the statistical model and the data in Table 1.

A convenient linear approximation of the relationship for non-dwarf galaxies ($M_B^* \leqslant -16.0$) is

$$M_B^*(G) = -16.0 - 1.20\ (\Delta m_1 - 7) \qquad (1)$$

where $\Delta m_1 = B_1(\mathrm{CL}) - B_T^*(G) \geqslant 7$. It is because $\delta M_B(1)/\delta M_B^*(G) = 0.2$ only that $M_B(1)$ was initially believed to be a constant[13,14]. Equation (1) can be regarded as an empirical fit of the data which applies irrespective of the validity or otherwise of the underlying statistical model.

Distance modulus of the Vir I cluster

Application of equation (1) to the six brightest E galaxies in the cluster, including M87, with $\langle B_T^*(G) \rangle = 9.9$ and $\langle B(\mathrm{CL}) \rangle = 20.3$, that is, $\Delta m_1 = 10.4$, leads to $M_B^*(G) = -20.1$, and $\mu_B = 30.0$ (the brightest cluster magnitude B_1(CL) is defined statistically by a gaussian fit of the luminosity function[16]; it does not depend on the highly uncertain identification of any particularly cluster as the brightest. Galaxy magnitudes $B_T^*(G)$ are taken from ref. 15). The five fainter E and L galaxies in the Hanes[3] study have $\langle B_T^*(G) \rangle = 10.9$ and $\langle B_1(\mathrm{CL}) \rangle = 20.8$, then $\Delta m_1 = 9.9$, $M_B^*(G) = -19.5$, and $\mu_B = 30.4$. This value is preferred because it does not require an extrapolation of equation (1) beyond the range of $M_B^*(G)$ in Table 1. The mean error of the distance modulus is estimated at 0.3 mag, arising from the following components: 0.1 on B_1(CL), 0.1 on $\overline{M}_B$(CL), 0.15 on the median magnitude of cluster variables, 0.15 on the basic data[1], and 0.15 from the statistical model and related approximations, including neglect of cluster depth. The adopted modulus of Vir I from the brightest globular clusters is, then, $\mu = 30.4 \pm 0.3$; it is compared in Table 2 with estimates by other methods. The disagreement between the brightest cluster method and other methods[6] has been greatly

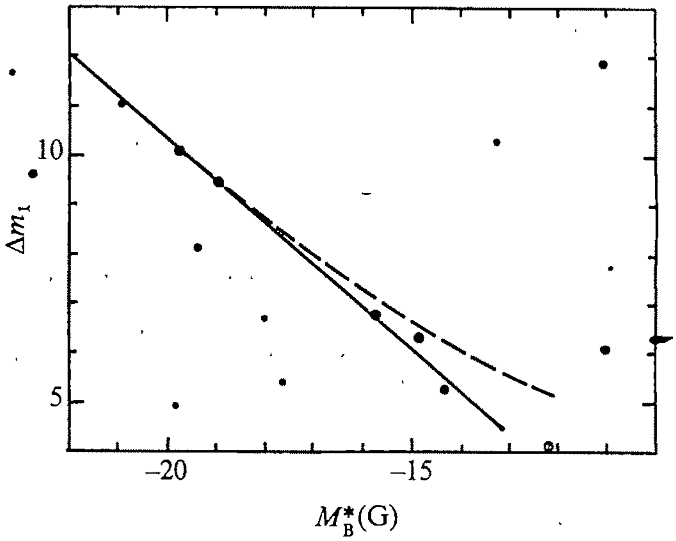

Fig. 3 Relation between magnitude difference $\Delta M_1 = B_1(\mathrm{CL}) - B_T^*(G)$ and absolute magnitude of spheroidal component of galaxy $M_B^*(G)$. The dashed curve is from theory ($\sigma = 1.1$ mag) and the linear approximation is from equation (1).

Table 1 Observed and calculated absolute magnitudes of brightest globular clusters

reduced (actually reversed) and all methods now agree within their errors with a mean modulus $\mu = 30.65 \pm 0.15$. Correcting μ for $A_B = 0.20$ mag of galactic extinction, the geometric distance modulus is $\mu_0 = 30.45 \pm 0.15$, corresponding to Δ(Vir I) = 12.3 (1±0.07) Mpc.

Distance modulus difference $\delta\mu_0$ between For I and Vir I

Several estimates of $\delta\mu_0$ are collected in Table 3; $\delta\mu \simeq \delta\mu_0$ because galactic extinction is very nearly the same in the directions of Vir I ($A_B = 0.20$ mag) and For I ($A_B = 0.21$ mag) in spite of the difference in galactic latitudes[25]. Considering the uncertainties of the basic data and underlying assumptions, the agreement between the different methods is rather good; the unweighted mean (rejecting low-weight of preliminary values in parentheses) is $\overline{\delta\mu_0} = +0.7 \pm 0.15$, implying a distance ratio Δ(For I)/Δ(Vir I) = 1.38 (1±0.07), a geometric distance modulus $\mu_0 = 31.15 \pm 0.2$ ($\mu = 31.36$), and a distance Δ (For I) = 17.0 (1±0.10) Mpc.

Table 4 Distance modulus of Hya I cluster

Method	μ_0
B_1(CL) and equation (1)	33.0
ΔB_1(CL) from M 31 ($\mu = 24.8$)	33.0
$\Delta\mu_0$ (Vir-Hya) = 2.55±0.2: from 3 brightest and largest E galaxies	33.0
Adopted mean	33.0±0.2

Approximate distance modulus of Hya I cluster

The brightest globular cluster method now agrees with all other reliable distance indicators, so an approximate value of Δ(Hya I)

			Adopted mean		86 (1±0.10)

may be derived from the work of Smith and Weedman[4]. From their Fig. 2 the apparent magnitude of the brightest clusters in NGC 3311 may be estimated provisionally at $22.8 < B_1(\text{CL}) < 23.8$, say $B_1(\text{CL}) = 23.3 \pm 0.2$ The Galaxy, one of the two brightest ellipticals in Hya I, has a total magnitude $B_T(G) = 12.7 \pm 0.1$ (ref. 15); thus $\Delta m_1 = 10.6$ and, from equation (1), $M_B{}^*(G) = -20.3$, $M_1(\text{CL}) = -9.7$ and $\mu = 33.0$. Since $M_B{}^*(G)$ for M 31 and N3311 differ little, a direct comparison of the first-ranked clusters is legitimate; then $\Delta\mu(1) = 23.3 - 15.05 = +8.25$ and $\mu_0(\text{Hya I}) = (24.8-0.43) + (8.25-0.38) = 33.0$. From a comparison of corrected apparent magnitudes and diameters of the three brightest elliptical members in each cluster, the differential modulus is $\Delta\mu_0$ (Hya–Vir) $= 2.55 \pm 0.1$: and $\mu_0(\text{Hya}) = 33.0 \pm 0.2$. The adopted mean of the values collected in Table 4 is $\mu_0 = 33.0 \pm 0.2$ and $\Delta(\text{Hya I}) = 40.5$ $(1 \pm 0.10{:})$ Mpc (with a galactic extinction $A_B = 0.38$ (ref. 15)).

Local value of the Hubble ratio

Recent or new estimates of the mean corrected redshifts of the Vir I, For I and Hya I clusters are collected in Table 5. To bypass the controversy[17–19] concerning the equality or otherwise of the mean redshifts of the Virgo I E cluster and S cloud, and because For I and Hya I are both E-type clusters with dense cores, the mean redshift of the 3° = 0.6 Mpc core of the Virgo E-cluster may be considered more appropriate for a direct comparison with the other two clusters. (Also, spirals in the S-cloud have a much larger velocity dispersion[18,19] and may degrade rather than increase the precision of $\overline{V}_0$.)

The comparison is summarised in Table 6 where the values of the mean velocity-distance ratio $'H' = \overline{V}_0/\Delta$ are derived from the adopted redshifts and distances. It is clear that the three clusters are in general agreement with much other evidence to support a mean value $'H' = 86\ (1 \pm 0.1)$ km s^{-1} Mpc^{-1} as the proper local average of the Hubble ratio, significantly higher than the often quoted values of 57 (ref. 10) to 50 (ref. 11). This persistent disagreement underlines the importance of current efforts to derive the distances of clusters more distant than Vir I in several directions well away from the centre of the Local Supercluster.

I thank Drs J. A. Dawe and R. J. Dickens for communication of their report in advance of publication, Dr M. G. Smith for useful discussions of his recent work, and Dr D. A. Hanes for a prepublication copy of his dissertation and his valuable criticism.

Nile Cone: Late Quaternary stratigraphy and sediment dispersal

D. J. Stanley

Seccion de Estratigrafía, Instituto 'Jaime Almera', C.S.I C., Barcelona, Spain

The cyclic nature of Late Quaternary Nile Cone sediments is a response to major climatic oscillations, including marked changes in sea level, Nile River discharge and sediment influx and water mass stratification. Deposits have accumulated most rapidly north-west of the Nile Rosetta Branch since the Early Würm A broad area of low sedimentation on the Cone, initiated during the Holocene sea-level rise, is predicted to increase in size as a result of the Aswan High Dam and modification of Nile River flow.

THE Nile Cone, largest of the Mediterranean deep-sea fans, has a complex history related to the large-scale tectonics of the Levantine Basin[1–3] and evolution of the Nile River which has served as its major sediment source Deposition on the Cone in the Quaternary has differed from that on most other large subsea fans in one important aspect, that is, sediments carried seaward of the Nile accumulated in a relatively small enclosed water body and thus have been extremely susceptible to climatic changes affecting this region. The deposits record modifications of eustatic sea level, Nile River, headwater migration and flow, physical oceanography, including current patterns and stratification,

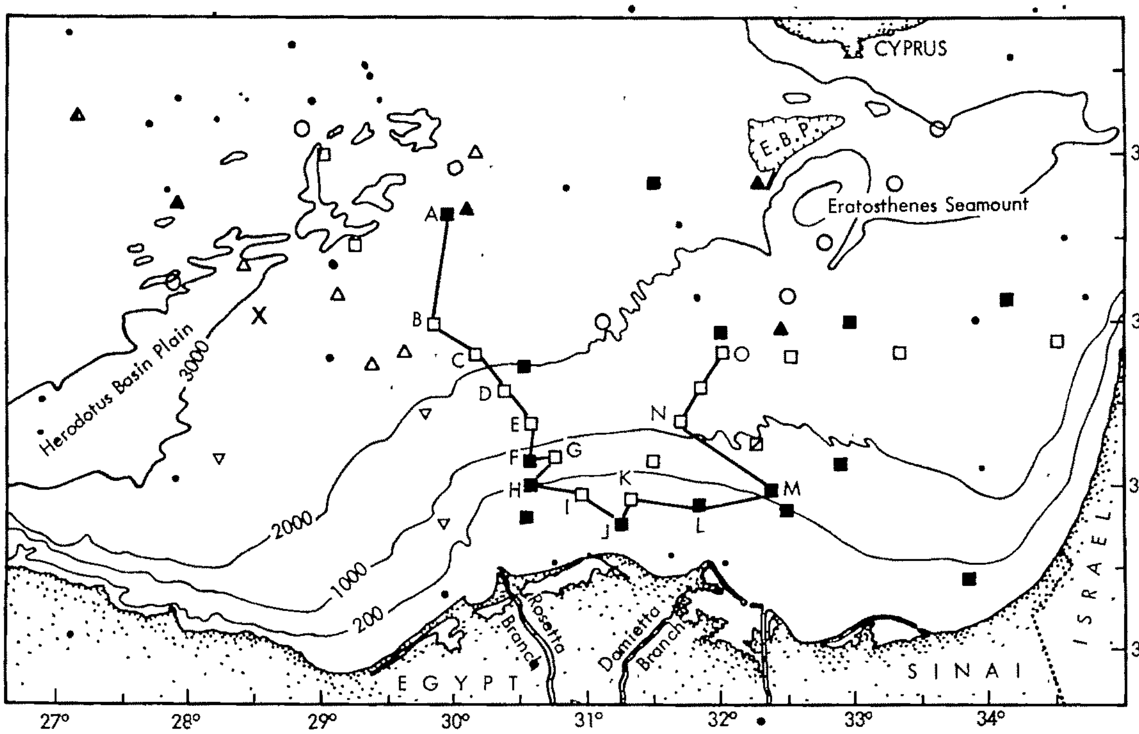

Fig. 1 Chart of the southeastern Mediterranean showing Nile Cone cores examined in this study. EBP, Eratosthenes Basin plain. Depth in metres. ○, Chain 61; ■, Pillsbury 6508; □, Pillsbury 6510; △, Vema 10; ▽, Vema 14; ▲, R. D. Conrad 9; ×, Deep Sea Drilling Project.

and biogenic productivity in front of the Nile. The emplacement of the Aswan High Dam and near-cessation of fluvial input seaward of the delta[4,5] are now altering the natural evolution of the Egyptian Shelf and Cone. The detailing of Late Pleistocene to Holocene depositional patterns, of which little is known, is of value in predicting changes likely to occur seaward of the subaerial delta.

The stratigraphy of the eastern Mediterranean is discussed in a number of studies[6–15]. Our earlier investigations emphasised the remarkable variety of sediment types forming the Cone and their cyclic nature[16,17]. Here, time and spatial variations of the uppermost sedimentary cycles are defined. We believe this cyclicity records large-scale Würm to Recent climatic events which have directly affected the depositional history of the southeastern Mediterranean.

This study entails analysis of 47 piston and gravity cores (Fig. 1), of about 1–15 m length, from the collections of: University of Miami RV Pillsbury cruise 6508 (15 gravity cores) and cruise 6510 (13 gravity and three piston cores); Woods Hole Oceanographic Institution RV Chain cruise 61 (five piston cores), Lamont-Doherty Geological Observatory RV Vema cruise 10 (five piston cores) and cruise 14 (three piston cores), and RV Conrad cruise 9 (three piston cores). Pillsbury and Chain cores are the best preserved. Core analysis includes X radiography, size analysis, total carbonate and organic matter, SEM, clay and sand fraction composition.

A total of 34 Pillsbury core samples provided radiocarbon dates (Table 1, R Stuckenrath, Smithsonian Radiocarbon Laboratory, personal communication). Dates were obtained from bulk samples about 10–30 cm in length. This method allows a small amount of core section to be used for dating and our tests show that dates so obtained are comparable to those obtained using only the sand-size planktonic foraminifera and pteropod fraction (cf. Pillsbury 6510-14 core section 21–61 cm). X-radiograph analysis reveals that sapropel samples selected for radiocarbon dating are finely laminated and not contaminated by bioturbation.

Correlation shows that sequences in the narrow diameter (4 cm) gravity Pillsbury cores are usually compressed relative to those in wider diameter (6.5-cm) piston cores, that is, 100 cm of piston core equals about 60 cm of gravity core section (cf. comparative scales along logs in Figs. 2). Piston and gravity cores of the same diameter (6.5 cm) may show a reverse trend, that is, piston core sections compressed relative to gravity core sections (C. Summerhayes, personal communication). Thickness data from piston cores serve as the basis for calculating sedimentation rates; thicknesses in gravity cores are recalculated to correlate with those of piston cores.

Late Quaternary stratigraphy

The simplified graphic logs of 15 of the 47 cores studied in detail are shown in Fig. 2; these are cores for which carbon-14 dates are available. Two well preserved piston cores, Pillsbury 6510-4 (1190 cm long) and 6510-14 (1528 cm long), collected respectively north-east of the Damietta Branch (1634-m depth; Fig. 1, core O) and north-west of the Rosetta Branch (2295 m; Fig. 1, core C) are used as types sections for the chrono- and lithostratigraphical analysis of the Late Quaternary sequence. These cores, collected in two different Cone sectors, show a complete sequence of sediment types without any apparent discontinuity.

The cores on the shelf and upper slope (to about 450-m depth) include three major sediment types in order of decreasing importance grey homogeneous mud (usually bioturbated), characterised by pelecypods and other benthonic and planktonic components; bioclastic neritic calcareous sand and gravel ('maerl') which display lithological transitions with the grey mud type; and terrigenous shelly sand and silt, including nearshore and pro-deltaic deposits. Two other sediment types, well-represented on the shelf[18] but not usually recovered in cores, are coarse, well-sorted, quartz-rich sands (reworked relict coastal sediment) and calcareous deposits of encrusting algal origin. The upper part of cores on the outer shelf and upper slope usually displays a distinct neritic calcareous sand dated between about 2700 and 2000 yr b.p. The upper part of cores on the inner shelf displays this horizon, and may also show a similar calcareous layer of sub-recent to modern age above it near the core top (c.f. core Pillsbury 6508-41, Fig. 2). In mid-shelf cores, a lower layer of neritic calcareous sand, separated from the upper calcareous sand by grey mud, is dated at about 16,000 yr b.p. (Pillsbury core 6508-42). The short length of shelf cores precludes an analysis of older Quaternary facies.

Cores collected at depths beyond 550 m on the slope consist essentially of six sediment types: turbiditic sand and silt, turbiditic mud, hemipelagic mud, calcareous ooze, organic ooze and proto-sapropel, and sapropel (defined in ref. 16). Also distinguished is a yellowish-orange to light brown mud termed oxidised layer (OL); where present, it usually caps a sapropel sequence. Clean, well-sorted quartz sands also are present in a few cores on the Cone seaward of Rosetta Branch. In both Pillsbury type cores, hemipelagic mud predominates (about 50% of the total core section). The repetition of sediment types which recur from bottom to top is noteworthy: grey hemipelagic mud→sapropel and organic ooze→calcareous ooze. Each complete cycle is defined as a cyclothem[17]. Incomplete silt-to-mud turbidite sequences occur indiscriminately throughout each cyclothem (Fig. 2).

Table 1 Radiocarbon dates based on bulk sample (except P6510-14P, 21–61 cm) from cores selected in different physiographic areas of the Nile Cone and adjacent areas (G, gravity core; P, piston core; p, pilot gravity core)

Core	Type	Depth (cm)	Sediment type	Radiocarbon date (yr b.p.)	Notations
P6508-34	G	0–8	Calcareous ooze	2,795±75	
		100–115	Organic ooze	9,305±85

*Small sample, diluted and counted at reduced pressure.

The upper three cyclothems present distinctive suites of lithological characters enabling each to be identified in the study area. The uppermost (cyclothem 1) is distinguished by an oxidised layer above a well-marked sapropel (S_1) layer 8–20 cm thick, thick organic ooze layers above and below the sapropel, and a general absence of turbiditic layers above the oxidised layer. The second (cyclothem 2) comprises a poorly developed sapropel (S_2), and usually has two distinct calcareous ooze layers at the top separated by hemipelagic mud; it is sometimes difficult to identify this cyclothem, but the well-defined calcareous layer (C_3) of the underlying third cyclothem delineates the base of cyclothem 2. The third (cyclothem 3) shows a well-developed sapropel layer (S_3) but, unlike cyclothem 1, usually includes a reduced proportion of turbiditic layers below the sapropel. This cyclic sequence varies from core to core in terms of thickness and absence of some sediment types.

The age of regionally important stratigraphic horizons in the three cyclothems is determined on the basis of radiocarbon dating (Figs. 2, 3 and Table 1). From top to bottom, the upper calcareous ooze (C_1) is about, or somewhat younger, than 2,700 yr b.p.; the oxidised layer (OL_1) is about 5,700 yr b.p.; the upper sapropel (S_1) ranges in age from about 6,600 to more than 8,200 yr b.p.; the calcareous ooze (C_2) top of the second cyclothem is dated about 17,000–19,000 yr b.p.; the second sapropel (S_2) is about 23,000–25,000 yr b.p.; the calcareous ooze (C_3) top of the third cyclothem is dated about 28,000–33,000 yr b.p.; the sapropel (S_3) in this cyclothem is roughly dated at 38,000–>40,000 yr b.p. The top of the fourth cyclothem (C_4) is considerably older than the resolution of carbon-14 method; a maximum age of 55,000–58,000 yr b.p. is estimated based on its position relative to the overlying dated horizons (Fig. 3, log 1).

For calculation of sedimentation rates, the following ages in yr b.p. are assigned to the top of the regionally prevalent stratigraphic horizons: OL_1=5,700; C_2=17,000; S_2=23,000; C_3=28,000; S_3=38,000; and C_4=55,000–58,000. The sapropel dates correlate relatively well with radiocarbon-dated sapropel sections of some workers[11]. Our sapropel 2 and 3 dates, however, are much younger than those obtained by other techniques (Ryan[12], for example, attributes an age of about 80,000 yr b.p. to S_3 which is not consistent with our findings).

It is useful to compare the combined litho- and chronostratigraphical sequence with generalised eustatic sea-level curves (modified after refs 19–21). The correspondence of cyclothems 1 and 2 with the Bloom *et al.* (1974) data is generally good, while the cyclothem 3 correlation is not so clear cut. The younger, more reliably dated cyclothems 1 and 2 are initiated with slight offset at times of maximum low and high sea levels (Fig. 3). Consideration of the climatic curve based on the Camp Century ice core[22] reveals a good correspondence for cyclothem 1 (warming after the Late Wisconsin); cyclothem 2 correlates with the Wisconsin II, between the Plum Point climatic maximum and the beginning of the Holocene rise; cyclothem 3 seems to correspond well with the Middle Wisconsin between about 30,000 and 58,000 yr b.p. including both Plum Point and Port Talbot maxima (D. J. Colquhoun, personal communication).

Calcareous ooze layers, consisting of abundant calcareous nannofossils and Mg-calcite in the form of poorly defined crystals, seem to develop at times of high and low sea-level stands, while the dark organic-rich sapropel layers accumulated during phases of rising as well as lowering sea level (Fig. 3). The relationship between lithology and the Camp Century and eustatic curves suggests the following: C_1 at about 2,700 yr b.p. may have been deposited during a time of slight sea-level lowering and probably cooler (*Littorina*) conditions than earlier. S_1 occurs almost 2,000 yr after climatic amelioration, and generally within the climatic optimum, at a time when the rate of Holocene sea-level rise had generally decreased. C_2 was deposited before the increase in temperature that resulted in the Holocene rise and probably during a time of slight temperature decrease which may also have been reflected in a slight sea-level lowering. S_2 may correspond to a warmer phase of the Late Wisconsin, and at about the same eustatic position as that of sapropel S_1, except for generally lower temperatures. C_3 occurs during a cooling phase from the Plum Point interstadial, with perhaps lowering sea level and temperatures. S_3 seems to occur close to the climax of a warmer period. The calcareous top of underlying cyclothem 4 may have accumulated during a cool phase leading into the Port Talbot interstadial (D. J. Colquhoun, personal communication). In this scheme hemipelagic and turbiditic sedimentation should prevail on the Cone at times of maximum sea-level changes when major delta front migration and Nile input alterations would be expected.

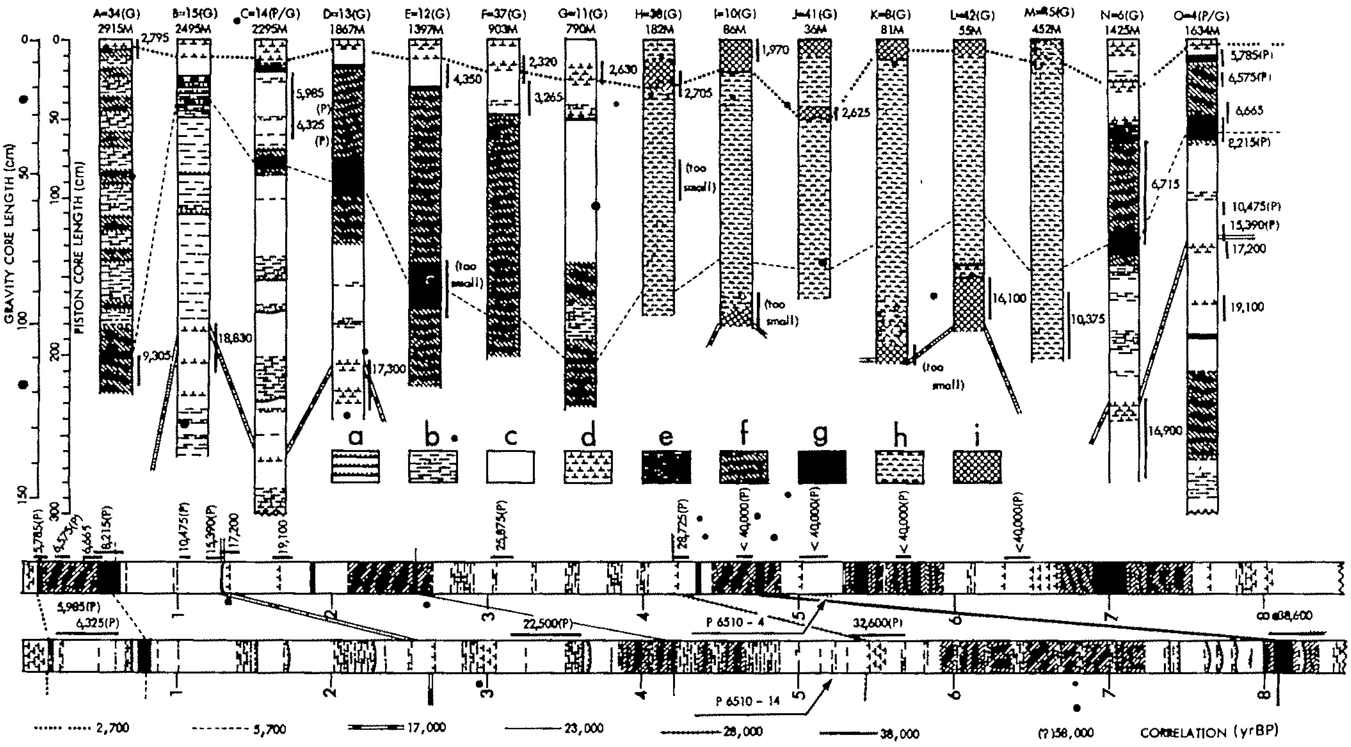

Fig. 2 Correlation of Nile Cone and Egyptian Shelf cores along two transects (position in Fig. 1) based on lithology and radiocarbon dating. Cores P6510-4 and -14 serve as types for defining the Late Quaternary stratigraphy in the southeastern Mediterranean. *a*, Turbiditic sand and silt; *b*, turbiditic mud; *c*, hemipelagic mud; *d*, calcareous ooze; *e*, oxidised layer; *f*, organic ooze and protosapropel; *g*, sapropel; *h*, grey (shallow water) mud; *i*, coarse calcareous sand and gravel. G, gravity core; P, piston core, p, pilot gravity core.

Sedimentation rate variations in time and space

The thickness measured between the major dated horizons in cores shown in Fig. 2 serves as a means to calculate sedimentation rates during six time periods in the late Quaternary. Depositional rates are contoured on six charts (Fig. 4) using a geometric scale to emphasise regional variations; the accuracy of contour line positions has been verified by supplemental lithofacies data from 27 Nile Cone cores collected on RV Chain 1975 cruise 119 (D. A. Ross and C. Summerhayes, personal communication). The charts reveal significant changes in sediment dispersal in the study area from the Early Würm to the present.

Low sedimentation rates are recorded during the oldest phase for which we have reasonable chronological control, that is, from about 58,000 to 38,000 yr BP (C_4 to S_3). The chart depicts minimal rates (about 1–16 cm per 1000 yr) since it is based on a limited number of cores which are long enough to recover the C_4 layer The rates may be higher than shown if the age of the C_4 layer is younger than the 55,000–58,000 yr BP postulated A broad lobe of relatively rapid sedimentation is observed on the upper Cone seaward of both Rosetta and Damietta branches (somewhat higher values occur off the Rosetta Branch). Low values occur elsewhere on the Cone, with lowest values recorded in the vicinity of the Eratosthenes Seamount. Deposits in this earliest time span considered here probably accumulated during several sea-level oscillations (Fig. 3) possibly related to the Port Talbot maximum[22]. We speculate that the calcareous ooze layer C_4 (base of cyclothem 3) was deposited during a low eustatic phase (termed the Early Würm[20], although no universally accepted sea-level curves are compiled for this period) before an interstadial (Plum Point) at about 30,000 yr suggested by some workers[19,21].

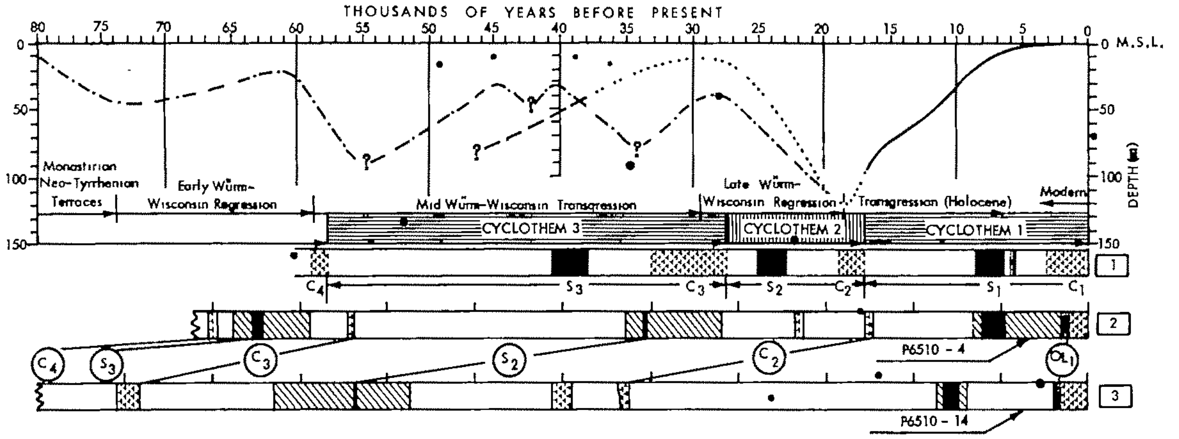

Fig. 3 Correlation between two Nile Cone stratigraphic type cores (logs 2, 3) and a generalised eustatic sea-level curve modified after refs 19–21. Log 1 shows the age of stratigraphic horizons and the upper three cyclothems in thousands of years before present; also shown is the position of the upper three cyclothems relative to sea level. OL_1 = oxidised layer above uppermost sapropel sequence; C_1, C_2, C_3, calcareous ooze layers; S_1, S_2, S_3, sapropel layers; · · · · · —— Curray[19]; — — — Fairbridge[20]; · — · — · Bloom *et al.*[21].

The depositional patterns are more distinct during the period between about 38,000 and 28,000 yr (S_3 to C_3). Rates range from about 1 to 26 cm per 1,000 yr, and most of the area is covered by sediment accumulating more slowly than 8 cm per 1,000 yr. A lobe of >16 cm per 1,000 yr is depicted on the Cone seaward of the Rosetta Branch; high values also occur off the Israel–Lebanon margin. This pattern developed either during a general rise in sea-level preceding, and perhaps coinciding with, the interstadial at about 30,000 yr BP (refs 19 and 20), or during a rising–lowering eustatic cycle[21] (Fig. 3).

Rates between about 28,000 and 23,000 yr BP (C_3 to S_2) range from 1 to >65 cm per 1,000 yr, and are generally higher throughout most of the region than in the previous period, that is almost half of the region is covered by sediments accumulating at >16 cm per 1,000 yr. Two well-marked lobes (>32 cm per 1,000 yr) occur seaward of both branches of the Nile; particularly high values are localised off the Rosetta Branch. This pattern evolved during lowering of sea level and reflects a steady increase of freshwater discharge and sediment supply from the Nile in response to climatic changes affecting the headwaters

Depositional changes are noted between about 23,000 and 17,000 yr BP (S_2 to C_2). The rates range from 3 to >49 cm per 1,000 yr, and at this time well over half of the area is covered by sediments deposited at >16 cm per 1,000 yr, reflecting the enhanced transfer of material on to the upper Cone sectors Patterns off the Nile are not distinct; low values occur off the Sinai, and two high sedimentation belts occur on the lower Cone, one extending SSW from Lebanon south of the Eratosthenes Seamount, the other (represented by three isolated areas) between the base of the Cone and the Mediterranean Ridge. The patterns, showing the highest rates over the largest areas, are related to the last major eustatic low stand when prodeltaic deposition extended seaward across the subaerially exposed shelf and large amounts of sediment were transported directly on to the slope. Mass gravity as well as hemipelagic and related suspension transport mechanisms were involved during this period of marked progradation.

From about 17,000 to 5,700 yr BP (C_2 to OL_1) depositional patterns once again become better defined. Sedimentation rates range from 3 to >88 cm per 1,000 yr; about a third of the Cone surface is covered by sediment accumulating at more than 16 cm per 1,000 yr, and half by 8 cm per 1,000 yr The highest rates appear channellised on the upper Cone and slope, and a relatively narrow NW-trending lobe extends from the Rosetta Branch towards the eastern part of the Herodotus Basin plain. An east–west zone of low sedimentation (<8 cm per 1,000 yr) forms on the Cone seaward of the Damietta Branch The more restricted extent of high sedimentation off the delta reflects a progressively decreased input of prodeltaic clastics paralleling the landward shift of the Nile depocentres during the rapid sea-level rise. This last major eustatic shift resulted in the proportionately increased role of hemipelagic sedimentation and diminished terrigenous influx from the Damietta sector of the delta

Sedimentation rates decrease further during the period between 5,700 yr BP and the present (OL_1 to C_1). Rates range from about 1 to 36 cm per 1,000 yr, and most of the Cone is covered by more slowly accumulating sediments (<8 cm per 1,000 yr). The highest rates occur on the shelf and upper slope, at the foot of the Cone, at the eastern section of the Herodotus Basin plain, and in the Eratosthenes Basin plain. The general decrease of rates away from land and absence of downslope channellisation patterns reflect the primary role of hemipelagic sedimentation and reduction of turbiditic mud incursions accompanying the stabilisation of sea level at about its present stand. The large east–west belt of low sedimentation is amplified as a result of the diminished role of the deltaic point source and relatively greater importance of lateral suspensate transport and smoothing by predominantly east–west trending surface water flow above the Cone[23–25].

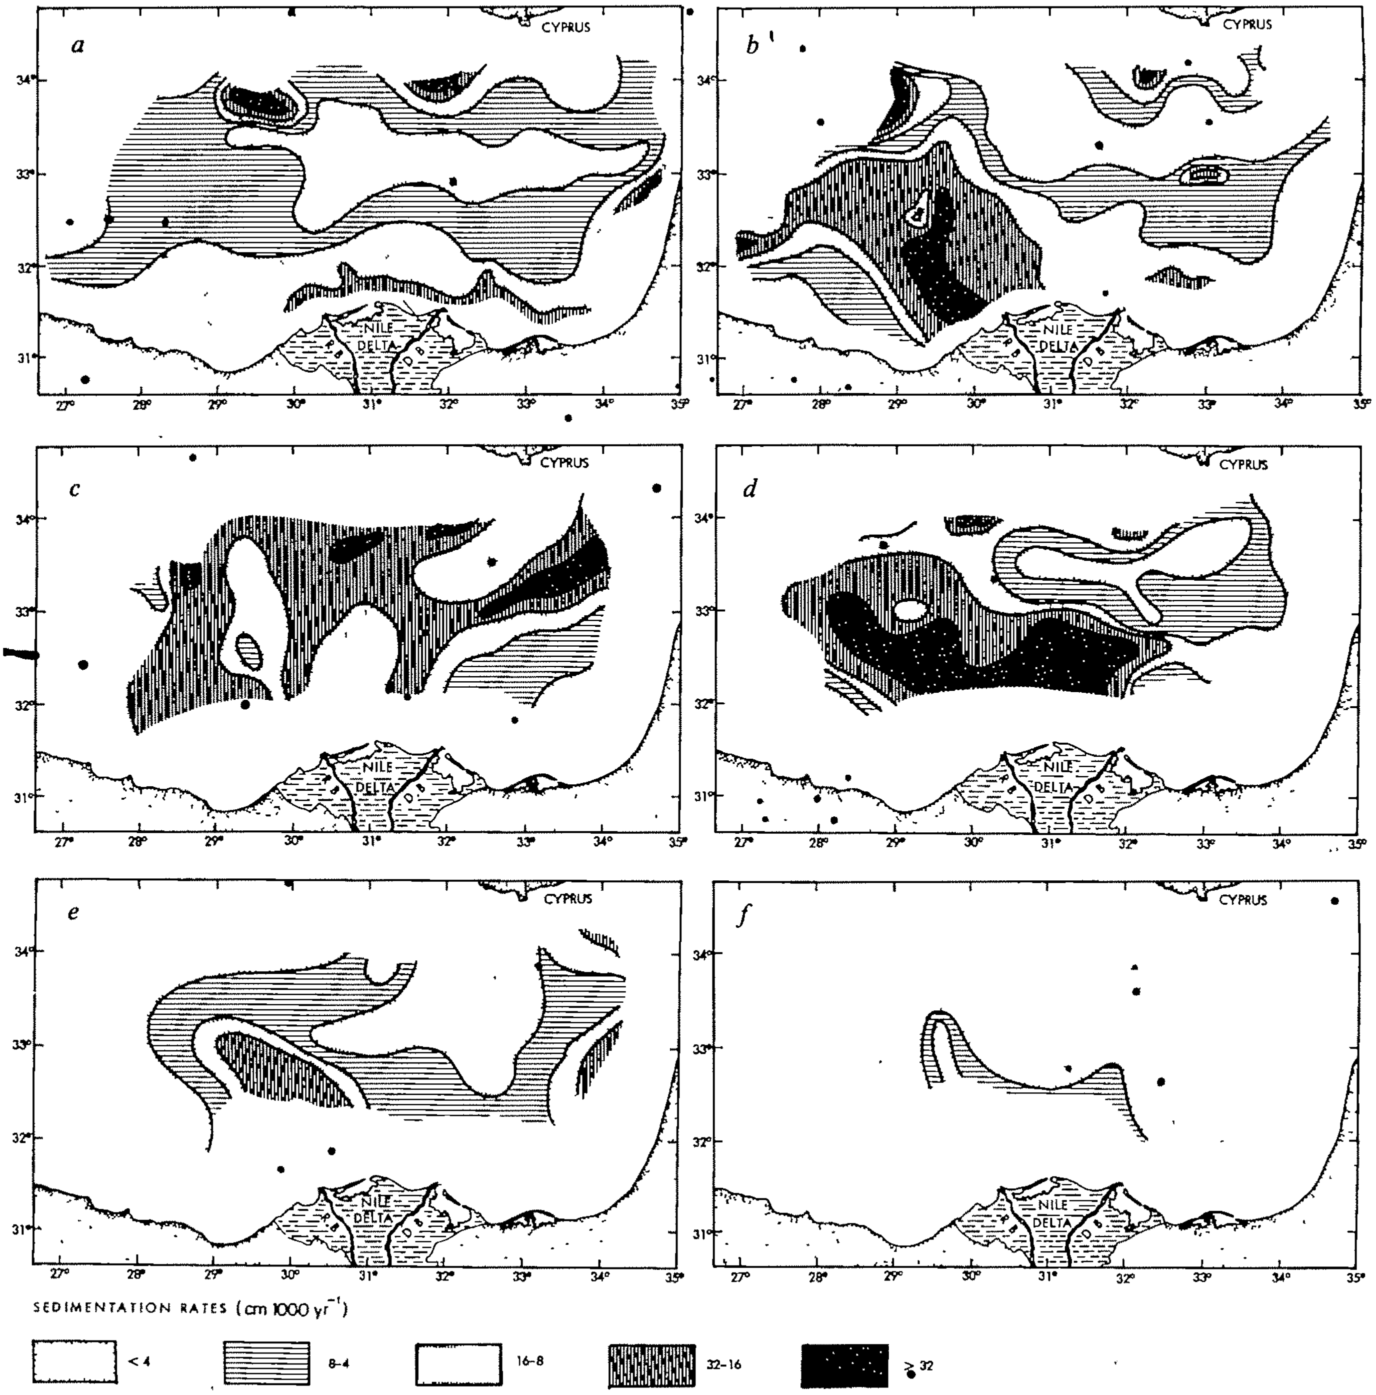

Fig. 4 Charts showing sedimentation rates (in cm per 1,000 yr) on the Nile Cone and adjacent areas during six periods in the Late Quaternary. The stratigraphic horizons used for correlation are shown in Figs 2 and 3. Explanation in text. *a*, OL_1–C_1 (5,700–present); *b*, C_2–OL_1 (17,000–5,700); *c*, S_2–C_2 (23,000–17,000); *d*, C_3–S_2 (28,000–23,00); *e*, S_3–C_3 (38,000–28,000); *f*, C_4–S_3 (58,000–38,000). Discussion

The orderly and repetitive nature of Late Quaternary sediment types on the Nile Cone and adjacent south-eastern Mediterranean reflects the interplay of sedimentation with highly variable climatic[1,26,27], physical oceanographic[28] and biogenic against terrigenous input factors in a quasi-enclosed silled basin. The core data presented here establish a time-framework for the upper three cyclothems, and provide support for the previously suggested hypothesis that the cyclic nature of major lithofacies in this region is a direct response to climatic factors[17]. Specifically, we show that cyclothems correspond closely in time with either major eustatic rise or lowerings of sea level, and that the beginning of each new cyclothem appears slightly offset (delayed) from the beginning of an oscillation (Fig. 3).

The dated calcareous ooze layers were deposited primarily during cooling temperatures and lowering sea-level stands. Several radiocarbon-dated samples of magnesium-rich layers in other eastern Mediterranean cores (ref. 29, their Table 3) correspond in age to Nile Cone calcareous ooze horizons C_2 and C_3 identified here. Similar calcareous ooze layers of about the same age also are recorded in the western Mediterranean[30]. The sapropels, on the other hand, accumulated during periods of rising or lowering sea level, and not at times of highest or lowest stands. Earlier work suggested they were deposited primarily during warming trends of climatic curves[12]; our study indicates they accumulated during early stages of temperature maxima. Sapropels record repetitive phases of stratification and near-bottom stagnation[5,15,28,31,32]. The general sapropel depositional model is characterised by (1) layering of water masses, (2) stagnation of bottom water with the formation of H_2S-rich zones and (3) seasonal (winter–summer) or periodical changes (eustatic-related upwelling and vertical mixing of water), all of which favour the development and preservation of varve-like bedding[15,33]. The oxidised layer found above the sapropels, the third cyclothem lithotype related to climatic and oceanographic phenomena, marks a return to oxygenated bottom-water conditions.

The time and spatial changes in sedimentation rates show the degree to which deposition has been directly affected by the Quaternary climatic–eustatic oscillations. The period of overall highest sedimentation occurred between about 28,000 and 17,000 yr BP; it is during this time span (last major Wurm regression) that cyclothem 2 was deposited. As sea level dropped and Nile River discharge patterns altered, an increasing volume of resuspended sediment was transported across large sectors of the delta front, including both the Rosetta and Damietta branches, and moved seaward directly on to the Cone. During this period sedimentation rates over large areas of the Cone are roughly equivalent to the high, long-term average rates (>30 cm per 1000 yr) previously postulated[3,14] for this and other submarine fans[34–37] during the Pleistocene. At times of rising sea level, sediment patterns on the Cone (cyclothems 3 and 1) show more restricted zones of sediment influx localised seaward of the Rosetta Branch, and an extensive east–west belt of low sedimentation over the central and eastern sectors of the Cone The latter records the diminished input from the delta and the relatively increased importance of suspension processes and regional smoothing by currents responding to large scale water mass flow over the Cone. As might be expected, lowest depositional rates are recorded at times of high sea-level stands, such as exists at present when the influx of the Nile is at a minimum due to the submergence of the Egyptian Shelf, landward regression of the prodelta lobe away from the shelf edge, and reduced freshwater discharge.

The most important zone of accretion on the Cone during the total time span (≃58,000 yr) considered here forms a SE–NW lobe which extends seaward of the Rosetta Branch toward the eastern part of the Herodotus Basin plain. The broad, highly dissected SE–NW trending belt east of this depositional tongue and north of the Damietta Branch[1] does not seem to have had a significant role in downslope channellisation of sediments during the Late Pleistocene–Holocene and even may have served as a barrier to the northward and northeastward transfer of clastics from the delta.

The Late Quaternary cyclothemic patterns of the type defined here occurred through much of the earlier Pleistocene, and possibly Pliocene, development of the Nile Cone and, if carefully documented, these older cycles may identify climatically-induced changes back in time. The stratigraphic generalisations can also serve to predict the future evolution of this submarine fan. In this respect, the emplacement of the Aswan High Dam and cessation of surplus Nile flood water discharging through the delta mouth is bringing to completion a process initiated with the rapid Holocene rise of sea level, that is, the reduction of seaward transported riverborne sediment. The present artificial 'closing-of-the-faucet' phenomenon has markedly altered the nature of suspended sediment and nutrients seaward of the delta and reduced the volume of material likely to reach the shelf edge. Immediate predictable results include lowered depositional rates on and beyond the shelf and a broadening of the east–west belt of low accretion on the Cone

This Mediterranean Basin (MEDIBA) study was funded by the Smithsonian Research Foundation, the National Geographic Society and the Consejo Superior de Investigaciones Cientificas of Spain. The following provided core materials· University of Miami, Lamont-Doherty Geological Observatory (supported by ONR and NSF grants) and Woods Hole Oceanographic Institution (supported by NSF grants). We thank Drs R Stuckenrath, Smithsonian Radiocarbon Laboratory, who provided the carbon-14 dates, and C. P. Summerhays, Woods Hole Oceanographic Institution, who furnished unpublished core data from RV Chain (1975) cruise 119. We acknowledge valuable discussion with Drs D. J. Colquhoun, F. W. McCoy, W. B. F. Ryan and C. P Summerhayes.

Monitoring the marine environment through sedimentation

A. Soutar, S. A. Kling, P. A. Crill & E. Duffrin

Scripps Institution of Oceanography, La Jolla, California 92093

Division of Natural Sciences, University of California, Santa Cruz, California 95060

The argument is advanced that the interception of particles settling within the water column provides a means of monitoring and understanding basic ocean processes. Geochemical and biological measurements on precisely dated bottom sediments and on preliminary recoveries from particle interceptor-traps provide supporting evidence.

ATTEMPTS to monitor and comprehend complex natural systems such as coastal seas and central oceans are characterised by the study of accessible parameters. These parameters are *a priori* presumed to be of importance, and it is further implied that a synthesis of accumulating information will eventually provide a sufficient description of the entire system.

Major problems in scaling arise if the relationship of discrete sampling to the continuous and long-term operation of natural systems is considered. In the case of the ocean this usually translates into the intermittent and non-synoptic measurement of a number of classic factors (such as temperature, salinity, major nutrients, chlorophyll, certain phytoplankton and zooplankton species, nekton and currents). These measurements are made at a number of point locations usually for very short periods, and extrapolations to the seasonal and longer-range character of the ocean are attempted In such a situation, though there occasionally may be an overwhelming number of samples, there is seldom sufficient information.

An alternative to increasing the number of measurements to gain sufficient data is to enlarge the scale of each measurement, making each observation representative of a relatively large area and significant period of time.

High-resolution bottom sediment records

Study of marine bottom sediments as a record of the overlying ocean is a long-standing and continuing[1] approach to increasing the scale of measurement. The apparent advantage of bottom sediment study is the access to material representative of prehistoric times, and were the open ocean and coastal seas unaffected by human activities, this would be the dominant attraction. If we are concerned with contaminant metals and hydrocarbons in the present marine environment, however, this proposition requires elaboration. The coastal sea lying directly off southern California is an important and convenient region on which to centre discussion.

The four nearshore coastal basins (Santa Barbara, Santa Monica, San Pedro and San Diego) adjacent to the southern California coast fall midway along a broad southward-flowing body of water known as the California Current[2]. The Santa Barbara, Santa Monica and San Pedro basins have impoverished bottom fauna zones as a direct result of their sills intersecting a dissolved oxygen minimum in the water column[3], and as a consequence, a virtually undisturbed sequential record of sedimentary phases accumulates. These basins, particularly Santa Barbara in the north, contain the greatest amount of information to be found in any sediment deposit, and this information can be resolved on time scales approaching 1 yr.

Utilising techniques that include box-coring devices that consistently obtain the exposed sediment surface, verification of surface sediment recovery through the presence of excess ^{228}Th, and stratigraphic dating by varve and ^{210}Pb chronology[4], detailed historical studies have been performed. In the Santa Barbara Basin sediments, these studies include common lead and its isotopic ratios[5], mercury[6] and the halogenated hydrocarbons, DDE and PCB (ref. 7) Metals including Pb, Cr, Cd, Zn, Cu and Ag have been analysed in the surface and near-surface sediments of the three suboxygenated basins[8]. Such studies not only provide a considerable perspective into baseline levels and subsequent anthropogenic increases of certain elements (Fig. 1*a*) but also most certainly indicate the sensitivity of sediments as an index to changes in the chemistry of the marine environment.

The range of factors available for examination in sediments is not limited to chemical considerations. Formation of a detailed chronological framework in sediments such as those of the Santa Barbara Basin gives a view of the long-term operation of the overlying biological system. This view is limited both by incompleteness of the sediment record and by the investigational effort needed to decipher the record, but is nonetheless remarkable. As an example, it has been found that fish scales of the two historically dominant pelagic species (Pacific sardine and northern anchovy) accumulate in the Santa Barbara sediments, and the accumulation is closely and directly related to fishery-derived population estimates for the entire southern California region[11]. This relationship leads to an estimate of the variation of fish biomass in past times (Fig. 1*b*) and also suggests that presently depositing scales are a likely index to present productivity.

A second instance can be drawn from the study of diatom assemblages in these same sediments. If the combined absolute abundances of a number of diatom species, thought to be indicative of warm subtropical waters, are compared through time to an index of California summer surface temperature, it seems that the two records are significantly and directly related[12].

It should be noted that there is internal evidence that information derived from basin sediments applies to a considerable areal scale. Studies of the relationship of regional rainfall patterns to sedimentation (A.S. and P.A.C., in the press) demonstrated that individual laminae in the Santa Barbara sediments often have sufficient morphological character for them to be traced between cores 5 km apart. This is one indication that horizontal forces operating in the water column can effectively disperse and homogenise sediment over large areas; furthermore, in the basin regions off southern California the

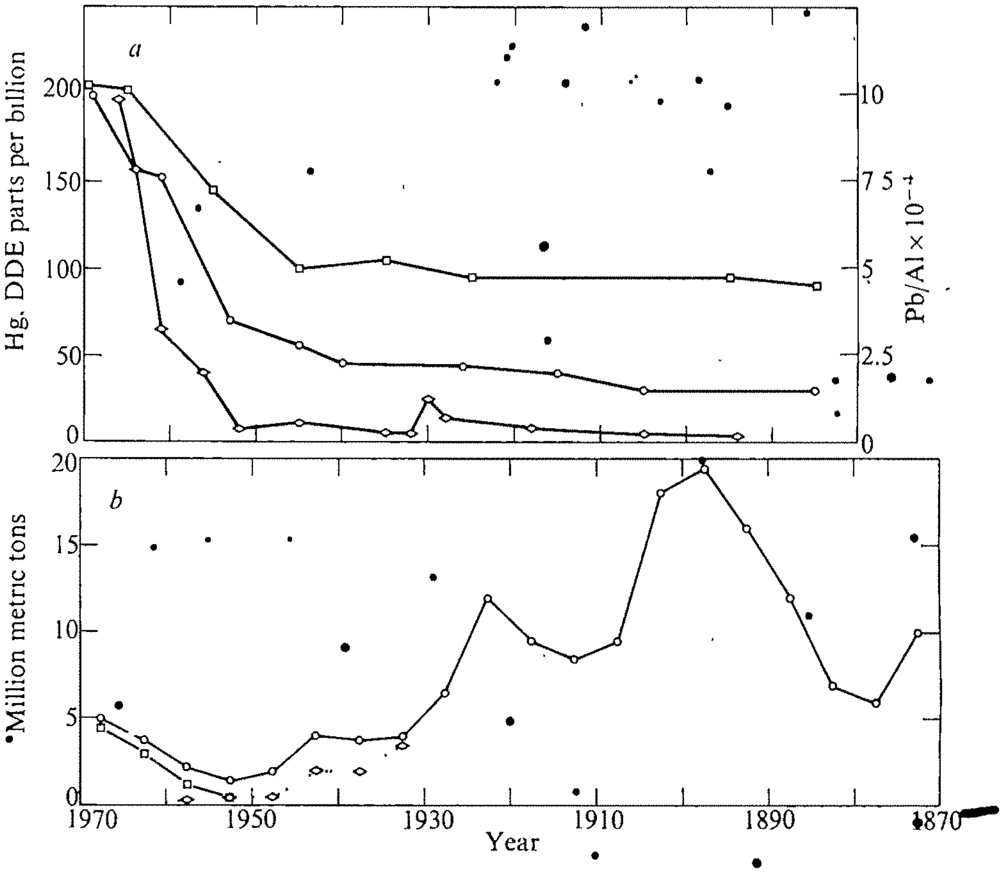

Fig. 1 Time series records from dated sediments off California. *a*, Lead[5] in the San Pedro Basin (○) and mercury[6] and DDE (ref. 7) in the Santa Barbara Basin (□ and ◇ respectively). The salt-corrected dry sediment concentrations of Hg and DDE are given in parts per billion, and Pb as a ratio of Pb/Al $\times 10^{-4}$ Other metal values for the Santa Barbara Basin 1970–71 surface sediments[8] are: Mn/Al $\times 10^{-4}$, 51; Fe/Al, 0.63; Ni/Al $\times 10^{-4}$, 7.3: Cr/Al $\times 10^{-4}$, 28; Zn/Al $\times 10^{-4}$, ~25, Co/Al $\times 10^{-4}$, 3.4, V/Al $\times 10^{-4}$, 44; Cu/Al $\times 10^{-4}$, 8.3; and Pb/Al $\times 10^{-4}$, 6. Corresponding values for metals in sediment recovered from a particle interceptor-trap deployed 100 m below the surface in Santa Barbara Basin during October 1971 are: Mn/Al $\times 10^{-4}$, 63, Fe/Al, 0.64; Ni/Al $\times 10^{-4}$, 4.5; Cr/Al $\times 10^{-4}$, 22; Zn/Al $\times 10^{-4}$, 107; Co/Al $\times 10^{-4}$, 1.5; V/Al $\times 10^{-4}$, 16; Cu/Al $\times 10^{-4}$, 13; and Pb/Al $\times 10^{-4}$, 16. *b*, Northern anchovy biomass estimates[9] (□), Pacific sardine biomass estimates[10] (◇), and combined pelagic fish biomass estimate (northern anchovy, Pacific sardine and Pacific hake) (○) derived from fish scale deposition in Santa Barbara Basin[11].

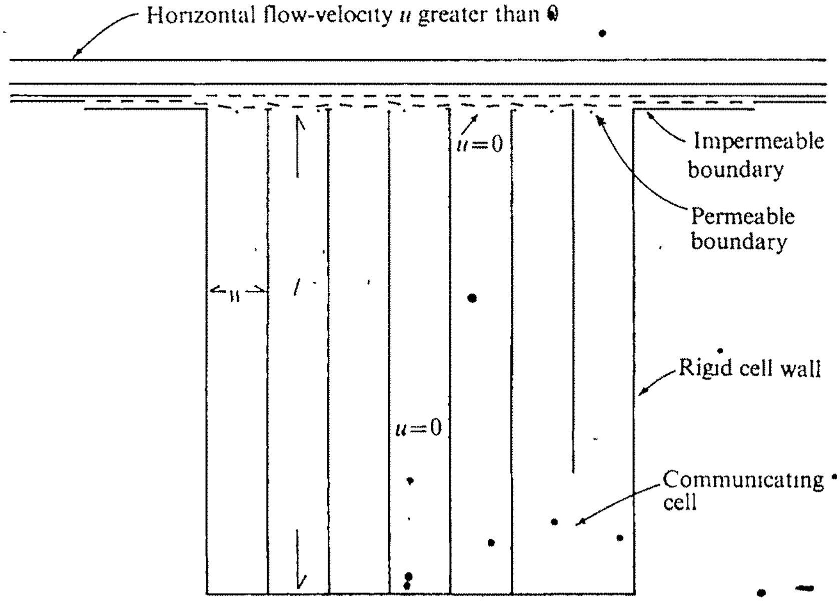
parameter values found in a reliable and documented core are generally good measures of any other reliable core recovered from the same basin, and overall the sedimentation of biogenic and terrestrial debris provide sensitive indices of regional climate, productivity and pollution.

Particulate sediment in the water column

If the bottom of the sea everywhere were similar in character to the Santa Barbara Basin, there would be little need of further elaboration. Varved sediment, however, is quite rare and Santa Barbara is the only known location in the coastal seas off the mainland United States. Although there are significant occurrences of laminated sediments within the Gulf of California, Mexico and the coastal seas off Peru, South Africa and Pakistan–India, the bottom sediment records that do exist are for the most part thoroughly mixed by benthic organisms and have low to moderate rates of deposition (1–100 cm per 1000 yr). Resolution is thereby limited in such accumulations to time scales greater than 100 yr.

Direct collection of sediment particles in the water column is a means of obtaining information reaching the sediment surface, with potentially higher resolution than most bottom sediment records. Particulates may be directly filtered from the water column by nets[13] or from water

Fig. 2 Empirical configuration of particle interceptor-traps Cross-section diagram of closed cell and communicating cell array with horizontal water flow. Provided cells are closed at the bottom (or in the case of communicating cells the length (*l*) is at least four times the width (*w*)) and the cell walls are rigid, a quasi-stable boundary regime will be maintained at the cell mouths. Steady horizontal flow (*u*) will exhibit some drag effects to about 1/5 *w* above the cell mouth; however, depending on the current velocity, penetration of drag-induced vertical movement ceases at 1/5 *w* or less into the cell mouth. For cell widths on the order of 1 cm or less, even with reasonably high current velocities (30 cm s^{-1} highest observed in tank), frictional drag will not induce horizontal currents or vertical turbulence within the cells In effect the water inside the cells, though still in open diffusional continuity with the overlying flow, is isolated, and only settling particles (and small organisms capable of swimming) may enter and accumulate in the cells. Since the cells are isolated, abiotic agents can be incorporated and maintained as a relatively denser brine at the bottom of the cells to minimise post-depositional grazing and bacterial effects.



samples[14]. Such collection provides a measure of particle concentration but suffers from a low yield and the high variability of non-synoptic point sampling. It seems that systematic collection of particulates by filtration would be a useful but limited monitoring strategy.

Interception and collection of sediment in gram amounts and direct assessment of particle flux is possible through the emplacement of particle interceptor-traps within the water column. In conditions of horizontal current flow these devices can, in effect, locally create a hydrodynamic environment[15] similar to that found at the sea floor and thereby induce sedimentation. The critical features of a sea-floor boundary region can be produced by a horizontal, open-top/closed-bottom cellular array (Fig. 2).

Table 1 Dry sediment accumulation in particle interceptor-traps (615 cm^2)

Region		Time down (h)	Dry sediment yield (g cm^{-2} yr^{-1})	Yield as fraction of long term bottom sedimentation rate*
Santa Barbara Basin 34°14′N; 120°01′W depth 580 m				
May 1969	150 m below surface	50	0.02	0.22
	30 m above bottom	50	0.03	0.33
December 1969	10 m above bottom	85	0.17	1.90
October 1971	100 m below surface	840	0.08	0.88
	10 m above bottom	840	0.09	1.00
October 1973	150 m below surface	810	0.03	0.33
	10 m above bottom	810	0.06	0.66
San Pedro Basin 33°30′N; 118°22′W depth 890 m				
May 1972	150 m below surface	640	0.01	0.36
	10 m above bottom	640	0.01	0.36
Soledad Basin 25°15′N; 112°41′W depth 520 m				
May 1969	150 m below surface	50	0.05	1.28
	180 m below surface	50	0.02	0.51
	40 m above bottom	50	0.03	0.77
	10 m above bottom	50	0.03	0.77
October 1973	150 m below surface	590	0.01	0.27
	10 m above bottom	590	0.30	7.70

*Bottom sedimentation rates[22]: Santa Barbara, 0.089 g cm^{-2} yr^{-1}; San Pedro, 0.028 g cm^{-2} yr^{-1}; Soledad, 0.039 g cm^{-2} yr^{-1}.

Sediment trap configurations that have been used in lakes[16] are essentially open-top standing tubes 5–15 cm in diameter. Such configurations, and indeed many others, are well suited for particle collection provided there is little or no horizontal current movement and the particles have a relatively fast settling velocity. In the sea, where near-bottom flow may average 1–5 cm s^{-1} and on occasion exceed 25 cm s^{-1}, the cellular grid array would seem to be more in harmony with the conditions of sedimentation. The situation can perhaps be visualised if the path of a diatom frustule settling at about 1 m h^{-1} and being carried along in a 2-cm s^{-1} horizontal current flow is considered. In this case the tangent path of the diatom will form a vector angle from the horizontal of less than 1°. Furthermore, the grid array configuration facilitates the practical engineering of collecting surfaces of 1 m^2 or greater necessary to yield sufficient material in the relatively slow sedimentation regime of the ocean[17].

It must be stressed that grid arrays acting as particle interceptor-traps provide a measure of particle flux and, as such, cannot everywhere provide a meaningful measure of sedimentation rates. In nearshore and shallow (less than 100 m) regions there may be considerable resuspension and temporary deposition. Particle interceptor-traps placed near the bottom in such areas can only be used to qualitatively describe sediment in transit. Quantitative collection can ideally be carried out in the waters lying above deeper (> 250 m) basins and gently sloping regions of permanent sedimentation.

Alternatively, the use of particle interceptor-traps is not limited solely to the estimate of particle flux in a long term monitoring context. For example, if concurrent with the interception of particles, the in-the-water particle concentration is measured, then, provided the concentration is reasonably stable, dividing the particle flux ($ML^{-2}T^{-1}$) by the particle concentration (ML^{-3}) gives an estimate settling velocity (LT^{-1}).

Since an initial attempt[18], we have used particle interceptor-traps of 615 cm^2 for preliminary studies off the coast of California These traps were routinely deployed on free drop systems[19] consisting of a radio and sight mast, connecting lines of varying lengths, subsurface flotation packs, particle interceptor-traps, timed-release devices and ballast. The system is released from the ship in the stated order and settles to the bottom with traps positioned from 10 m above the bottom to 100 m below the surface. After a preset time, the release closes the traps and releases the ballast or radio mast allowing the system to rise to the surface. In nearshore and other areas of good navigation a less expensive though more vulnerable system can be arranged with a surface marker buoy. Alternatively, an expensive though relatively more efficient arrangement is possible using telemetering acoustic recall devices.

Results that may be useful in considering particle interceptor-traps as a monitoring tool are as follows. The dry sediment yields for a number of drops are given in Table 1. The values for 100–150 m below the surface traps were 0.01–0.08 g cm^{-2} yr^{-1}. These projected values range from 0.22 to 1.28 times the underlying long term bottom sedimentation rates. The corresponding values for the

10–40 m above the bottom traps are 0.01–0.30 g cm^{-2} yr^{-1} and 0.33–7.70 times the bottom sedimentation rate. One of the extreme bottom values (Santa Barbara, December 1969) has been interpreted in conjunction with hydrographic observations as being due to a density flow deposit (turbidity current)[20]. The metal composition of sediment recovered from the Santa Barbara, October 1971 drop is given in the legend to Fig. 1*a*. Although these traps were not especially cleaned for metal investigations, with the exception of zinc, comparison of trap metal values and metal values of surface sediment in the same year are in general agreement.

Major seasonal differences in the aspect of intercepted sediment have been observed. In the Santa Barbara Basin, winter precipitation and storm wave activity lead to distribution and sedimentation of land detritus. Direct transportation of land detritus to the central basin region has been inferred as likely from the collection at 100 m of an essentially clay–silt sediment in the October 1971 trap. This trap was deployed 2 weeks before a substantial and first rainfall of the season (previous rainfall 6 months before) and was recovered 2 weeks after. Delayed distribution of land-derived detritus has been documented[21]. Sediment initially deposited on the shelf adjacent to the basin is progressively mobilised by subsequent storm waves and disperses towards the central basin on pycnocline surfaces near the 100-m depth. Sediment observed accumulating in traps deployed during the rainy season closely resembles the bulk composition of the Santa Barbara bottom sediments in that it is made up of clay flocculates with abundant silt particles. In contrast to winter deposition, material accumulating in the traps during the spring and summer seasons may on occasion differ substantially in appearance As an example, in May 1969 in both the Santa Barbara Basin and the Soledad Basin almost the entire fallout was made up of faecal pellets. The pellets contained no recognisable microfossil skeletal fragments in any of the size fractions (Table 2), and the percentage of organic carbon in these samples (18–20%) would indicate a transfer to the bottom of both basins at that time of about 0.2 g carbon m^{-2} d^{-1}.

In all seasons abundant and representative biogenic debris accumulate in particle interceptor-traps. Fish scales, pelagic molluscs, foraminifera, radiolarians, silicoflagellates, diatoms and coccoliths have all been observed. As a specific example, the group of warm-water indicator diatoms referred to in the bottom sediment discussion were well represented in both the surface and bottom traps deployed in October 1973. It is not possible to relate isolated monthly trap measurements to general temperature information, as little is known about seasonal differences in species abundance and productivity of diatoms off California. But the flux of diatoms in October 1973 projected for the entire year falls within the measured bottom sediment distribution. Furthermore, it should be stressed that all the above results are preliminary and indicate that particle interceptor-traps must be calibrated through year-long studies before they can be truly used as quantitative instruments in the marine environment.

Table 2 Estimated numbers of faecal pellets accumulating in particle interceptor-traps (50-h collection)

Region		Particle size range (μm)				
		>500	500–246	246–124	124–24	Total
SantaBarbara Basin						
May 1969	150 m below surface	600	6,000	6,000	30,000	42,600
	40 m above bottom	40	2,200	5,000	24,000	31,200
Soledad Basin						
May 1969	150 m below surface	0	50	6,600	~33,000	~40,000
	10 m above bottom	35	20	2,800	~20,000	~23,000

Monitoring the sea

It is difficult to devise a predictably successful monitoring strategy in the marine environment, for we consistently minimise the intricate nature of the sea and exaggerate our capabilities. Few programmes have ever set out to study persistently and record a substantial part of any marine environment; none have lasted intact much more than a decade.

If we are to assess the effects of future assaults on the seas and oceans, we must begin now to record marine conditions. We must monitor the chemical condition of the sea, paying close attention to the pathways and fate of heavy metals, anthropogenic hydrocarbons and artificial radionuclides. We must monitor the biological condition of the sea, trying to understand or at the least appreciate the fluctuations in productivity and species composition that do occur.

We feel that a unified monitoring of coastal seas and central oceans commensurate with available resources and a common responsibility for the future should soon exist[23]. Such an undertaking should involve a number of strategies. We contend that the interception of sediment particulates in conjunction with bottom sediment studies constitutes a major approach.

This report is a contribution of the Marine Life Research Group of the Scripps Institution of Oceanography. We thank the NSF for finance, and Professor J. D. Isaacs for criticism and support.

Penicillopepsin from *Penicillium janthinellum* crystal structure at 2.8 Å and sequence homology with porcine pepsin

The polypeptide chain of the acid protease penicillopepsin folds via an 18-stranded mixed β-sheet into two distinct lobes separated by a 30-Å long groove which is the extended substrate binding site. The catalytic residues Asp-32 and Asp-215 are located in this groove and their carboxyl groups are in intimate contact. Alignment of the amino acid sequence with that of pepsin shows regions of high homology.

ACID proteases are important in many diverse biological functions[1]. Fungal enzymes have been investigated as potential replacements for chymosin, the acid protease from calf stomach used in cheese production, owing to an ever increasing shortage of rennet. Acid proteases are also used in the preparation of fermented products from rice and soybeans. In mammals acid proteases function not only as extracellular digestive enzymes (pepsin, gastricsin) but also have a role intracellularly in protein turnover (cathepsins D and E (ref. 2)) and in the control of blood pressure (renin, the angiotensin-releasing kidney enzyme[3]).

Although chymosin has been used as an enzyme solution (rennet) for as long as 6,000 yr and although the first X-ray photographs taken of a protein crystal were those of pig pepsin[4], the study of the primary and tertiary structures of acid proteases has been slow. The complete amino acid sequence of only pig pepsin[5] is known and a preliminary communication[6] on its tertiary structure at 2.7-Å resolution has been published. Low resolution structures of two microbial acid proteases, one from *Rhizopus chinensis*[7] and the other from *Endothia parasitica*[8], have also been determined, but no detailed description of the polypeptide chain conformation for acid proteases has been published.

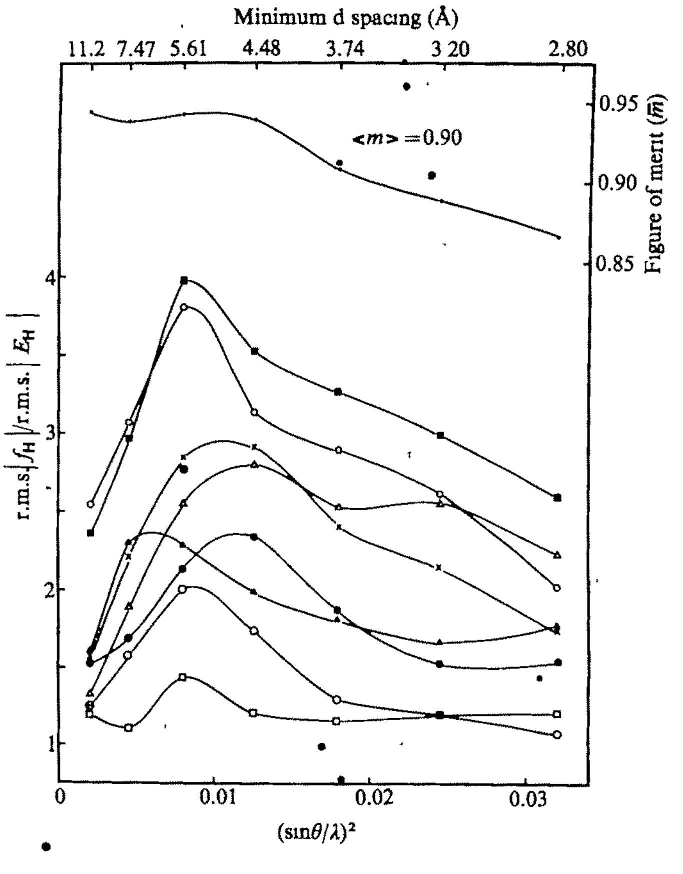
Penicillopepsin, the extracellular acid protease from *Penicillium janthinellum,* is an evolutionary homologue of pig pepsin and chymosin[9] as judged from a comparison of partial sequences. In addition, its specificity and catalytic mechanism are very similar to those of pig pepsin[10]. An aspartic acid residue important in the catalytic mechanism has been identified in a sequence which is nearly identical to one of the active site sequences of pig pepsin[9,11].

We present here the first high resolution structure of an acid protease in which the complete polypeptide chain can be traced unambiguously. The studies of the structures of the various acid proteases that are currently under way will demonstrate whether or not all these enzymes are homologous and belong to a single enzyme family such as the alkaline serine proteases[12–16]. Similarities and differences in their structures should also help to delineate specific mechanisms and substrate specificities. Our description of penicillopepsin at 2.8-Å resolution shows features which are likely to be common to many enzymes in this family.

Crystallography

Preliminary data for penicillopepsin crystals (monoclinic, space group C2, cell dimensions, $a = 97.38(8)$, $b = 46.62(3)$, $c = 65.39(6)$ Å, $\beta = 115.4(1)°$) from 2.5 M Li_2SO_4, 0.1 M sodium acetate, *p*H 4.4 were reported before[17]. A low resolution structure at 6 Å has also been described[18]. We used data collection and processing techniques described in the structural studies of the B protease from *Streptomyces*

Fig. 1 Phasing power of the eight heavy-atom derivatives used for the MIR phase determination of penicillopepsin. The ratio of r.m.s. $|f_H|$ to r.m.s. $|E_H|$ and the figure of merit ($\bar{m}$) are plotted as functions of $\sin^2\theta/\lambda^2$. ○, Uranyl acetate; △, $Pt(NH_3)_2Cl_2$; x double derivative (Pt + U); ●, mersalyl; □, K_2HgI_4; ■, $K_3UO_2F_5$; ▲, phenylmercuric acetate; ⊙, $IrBr_3$.



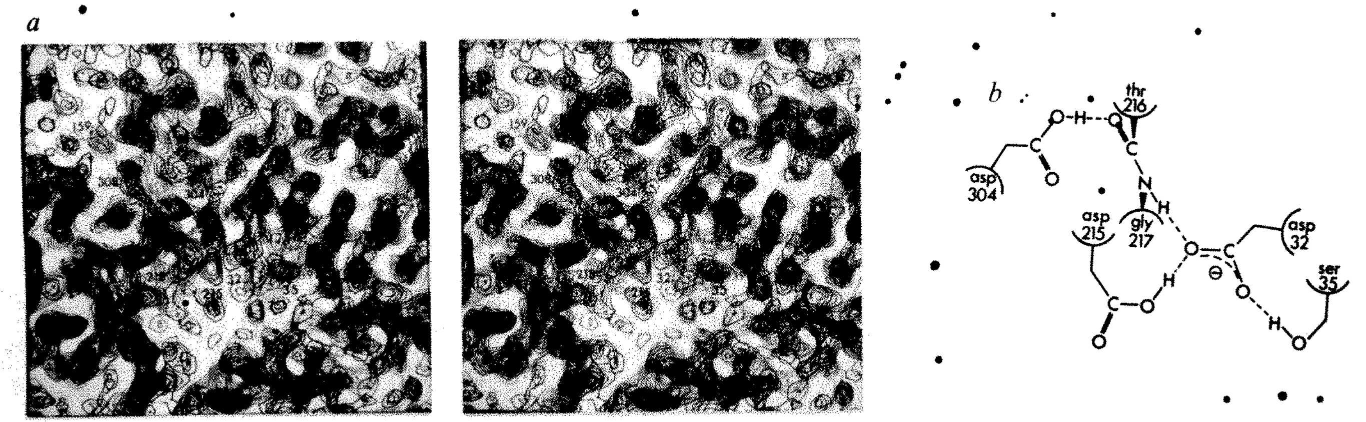


Fig 2 *a*, Stereoview of 10 sections (1-Å spacing) of the electron density map of penicillopepsin in the region of the catalytic site. The sequence numbers (see Fig. 3) are placed close to the side chains in this figure. The close contact of the carboxyl groups of Asp-32 and Asp-215 is in the central portion of the figure and the extended substrate binding groove lies below (in this figure) the active centre region. *b*, A tentative interpretation of the electron density in the vicinity of the active site of penicillopepsin. The carboxyl groups of Asp-32 and Asp-215 are approximately coplanar and share a proton as shown. Asp-32 is involved with two additional hydrogen-bond interactions, one to Ser-35, the other to the main chain NH of Gly-217. Asp-304 is an internally buried side chain and is involved with a hydrogen bonding interaction to the main chain C = O of Thr-216.

griseus[15,19]. The crystals of penicillopepsin were sufficiently stable to radiation damage in the X-ray beam to allow the collection of the complete 2.8-Å sphere of data (6,700 independent reflections) from a single crystal of the native enzyme and each isomorphous heavy atom derivative. The maximum loss in intensity of the monitor reflections was between 3 and 13% for the various crystals.

Eight heavy-atom derivatives were used to determine the phase angles for the reflections from the native crystals. The heavy-atom binding sites were identified either on difference Patterson maps or cross-phased Fourier maps which made use of the protein phases available from the 6-Å work[18]. Refinement of the heavy atom parameters was by the method of least-squares. For two derivatives, K_2HgI_4 and $IrBr_3$, the final heavy-atom model included two planar trigonal groupings of the HgI_3^- ion and $IrBr_3$. All heavy atom parameters, occupancies, temperature factors and positional parameters, behaved extremely well during the course of the least-squares adjustments with alternating cycles of protein phase angle determination. Table 1 shows the refinement statistics. Figure 1 shows the distribution of the ratio of heavy-atom scattering power (f_H) to lack of closure error (E_H) and of the mean figure of merit ($\bar{m}$) in ranges of $\sin^2\theta/\lambda^2$. The overall mean figure of merit for all observed data to 2.8-Å resolution was 0.90. It is clear from Fig. 1 and Table 1 that all eight heavy-atom derivatives provided useful phasing information to 2.8-Å resolution. The electron density map was computed from the 6,127 (91.4% of total) 'best' phases[20] with the measured native protein structure factor amplitudes. The high quality of the map may be judged from Fig. 2 by an examination of several sections computed in the region of the molecule containing the putative active site (Asp-32, Asp-215 in the pig pepsin numbering[5]).

Table 1 Heavy atom refinement summary

Derivative	Soaking time (d)	No. of sites*	Range A† (electrons)	Range B‡ (Å^2)	R_c§
1 mM $UO_2(C_2H_3O_2)_2$	7	3	11.5–22.6	6.9–18.4	0.512
5 mM $Pt(NH_3)_2Cl_2$	7	2	11.4–43.8	11.4–22.6	0.501
1 mM Pt + 1 mM UA	14	4	8.7–21.2	7.4–17.1	0.581
Mersalyl (saturated)	3	7	5.7–28.4	11.6–25.6	0.587
0.5 mM K_2HgI_4	3	5	5.4–27.6	5.3–20.7	0.626
5 mM $K_3UO_2F_5$	21	4	6.7–31.8	10.9–17.8	0.503
Phenylmercuric acetate (saturated)	7	7	6.6–42.7	9.1–17.9	0.569
2.5 mM $IrBr_3$	4	6	4.6–37.4	3.7–43.5	0.653

*Both the K_2HgI_4 and $IrBr_3$ derivatives had two sites which consisted of trigonal moieties (of HgI_3^- and $IrBr_3$, respectively).

†A is the site occupancy on an approximately absolute scale.

‡B is the isotropic temperature factor coefficient.

§$R_c = \Sigma||F_{PH} - F_P| - |f_H||/\Sigma|F_{PH} - F_P|$ summed over the centric data only.

Amino acid sequence

When the 2.8-Å resolution electron density map was computed, the primary structure was available in 16 fragments ranging in length from 3 to 112 amino acids[9]. In addition, there was tentative evidence for four overlaps. The map and the partial sequence data were used in conjunction to place 14 of the fragments in their proper order and to produce the sequence of penicillopepsin shown in Fig. 3. For two regions, 247–264 and 291–302, there was considerable difficulty in correlating sequence data with the electron density distribution. Residues 260–263 are consistent with the sequence of fragment PP6 in ref. 9. Residues 247–259 are consistent with much of fragment PP11 with the exception of the pentapeptide 249–253. In addition, the position of Cys-250 was not confirmed in fragment PP11. We have left residues 249–253 in brackets but the electron density in this region is consistent with the assignment of residues we have made based on the size, shape and spatial surroundings of these side chains. There is no doubt about the assignment of Cys-250 which is involved in the disulphide bridge 250–283. Eight residues from 295–302 satisfactorily account for the electron density in that region of the map and correspond in part to the C-terminal portion of fragment PP12 (ref. 9). Although residue 299 was chemically identified as Phe we have assigned Tyr to this residue based on the electron density associated with the side chain and the fact that a dipeptide Tyr–Leu was obtained in relatively high yield (11%) from a thermolytic digest.

Figure 3 also shows a possible alignment of the penicillopepsin sequence with that of pig pepsin[5]. A final alignment must await comparison to the tertiary structure of pepsin. The sequence information in Fig. 3 was used as input to A. McLachlan's comparison program[21] which showed 11 well defined regions of high homology (see also Fig. 4). The two regions of highest homology are those in the neighbourhood of the two active site aspartic acid residues (residues 29–42 and 212–221). The relatively high degree of sequence identity (32%) suggests that the tertiary structures of these two enzymes should be very similar with differences in conformation associated mainly with surface loops as has been

Fig. 3 Comparison of tentative penicillopepsin (Pen) sequence with porcine pepsin (Pep). Amino acid residues enclosed by solid lines are those regions of highest homology when compared with McLachlan's[21] sequence comparison program. Tentative sequence identity with pig pepsin: 102 residues = 31.7%. The single letter code for the amino acids is given in ref. 46. For penicillopepsin, the order of the fragments from chemical sequencing[9] with the residue numbers in this table is as follows: N-terminal fragment (−4 to 111); PP3 (111 to 121); PP7 (122 to 125); PP1 (126 to 138); PP2 (139 to 150); central fragment (151 to 197); PP5 (198 to 207); DAN (211 to 220); PP4 (221 to 231); PP10 (232 to 246); PP11 (247 to 259); PP6 (260 to 263); PP12 (265 to 299); X-ray map (300 to 302); C-terminal fragment (303 to 327). Fragments PP8 and PP9 (nine residues) have not been used in this sequence. There is a major discrepancy between the chemical sequence of PP11 and the electron density map. Sequence numbering is that of porcine pepsin[5]. The identification of residues enclosed in parentheses comes mainly from the electron density and not from chemical sequencing and therefore these regions are tentative.

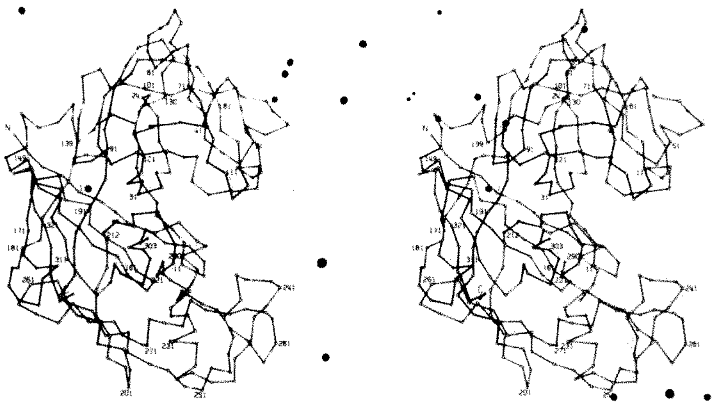

Fig. 4 Stereo-drawing of the main polypeptide chain in penicillopepsin. The circles represent α-carbon positions and only every tenth residue has been numbered (corresponding to the numbering of pig pepsin[5]). The regions of high amino-acid sequence homology (see Fig. 3) are drawn in dark lines. The bilobal feature of the molecule is evident; the active site is located in the groove that separates the two lobes.

observed in comparison of the bacterial serine proteases with the pancreatic enzymes[15,16,22,23].

Polypeptide chain conformation

The folding of the polypeptide chain of penicillopepsin is shown diagrammatically in Fig. 4. The overall dimensions of the molecule are approximately 65 × 49 × 39 Å and this asymmetric shape agrees with the dimensions reported for the low resolution studies of two other acid proteases[7,8]. The molecule is distinctly bilobal with an extended hydrophobic interior in the shape of a croissant. The two lobes are separated by a deep cleft which is approximately perpendicular to the 65-Å molecular length. Buried in the interior of this groove, but accessible to solvent, are the two catalytically important residues Asp-32 and Asp-215. The larger of the two lobes (upper part of Fig. 4) is made up of residues −4 to 171; the smaller lobe is composed of the C-terminal part of the chain.

The largest mixed β-sheet structure observed in globular protein structures is found in penicillopepsin and it consists of 18 strands of polypeptide chain. Figure 5 shows this sheet structure diagrammatically and we have described it according to the convention proposed by Richardson[24]. Not only is this the largest β-sheet observed in globular proteins but it also contains two cross-overs (±5X) that have not been observed previously[24]. This sheet starts at one end of the molecule (strand e is located in the uppermost portion of Fig. 4) and twists in the usual anti-clockwise fashion by 540° before reaching the final strand o. The central 10 strands are all anti-parallel, and the strands containing the active site aspartic acid residues (strands c and m) both have neighbouring parallel strands which are partly buried in the hydrophobic interior of the molecule. The topology of this sheet produces the croissant-shaped hydrophobic interior and there are 12 'hairpin' turns that are all located on the enzyme's surface.

Those stretches of polypeptide chain which adopt a helical conformation are 58–62, 137–141, 225–235 and 303-309. The single disulphide bridge in the molecule, Cys-250 to Cys-283 is located on the extremity of the smaller lobe (bottom right of Fig. 4). It is curious that this feature which seems to contribute little towards the overall stability of the structure is so highly conserved in acid proteases[5,9,25]. Porcine pepsin has two additional disulphide bridges, 45–50 and 206–210. The corresponding residues of penicillopepsin, although not cysteines, are sufficiently close to be connected by a disulphide bridge.

Catalytic site

Chemical studies of acid proteases, and the pH dependence of the catalytic rate constants of substrate hydrolysis implicate two carboxyl groups in the catalytic event; one in the protonated form, and the other in the unprotonated form[26]. The inactivation of porcine pepsin and penicillopepsin by diazoacetylphenylalanine ethyl ester[27] and diazoacetylnorleucine ethyl ester[11] (DAN) identified Asp-215 (Fig. 3) as one of the catalytic residues. The inactivation of porcine pepsin by 1,2-epoxy-3(p-nitrophenoxy)propane (EPNP) showed that Asp-32 was probably the other catalytic residue[28]. EPNP also inactivates penicillopepsin[29], although it has not been possible to isolate the labelled peptide. We assume that the site of reaction with EPNP is the same as that in pig pepsin because the electron density map (Fig. 2) shows clearly that the two carboxyl groups of Asp-32 and Asp-215 are in intimate contact. In addition, Asp-32 is in a sequence of five amino acids that are identical in the seven acid proteases examined[30].

Asp-32 is in strand c (Fig. 5 and legend) which is anti-parallel to neighbouring strand m which contains Asp-215. Both of these strands have neighbouring parallel strands h and p, respectively. Figure 3 shows the high degree of sequence homology for these two pairs of strands and the conformation of the chain in these pairs is very similar; both strand c and strand m have a sharp bend at the two glycine residues 34 and 217. There does not seem to be main chain hydrogen bonding between strands c and m, however there is clearly hydrogen bonding of Thr-33 side chain to the main chain between Ala-214 and Asp-215 and a corresponding interaction of the side chain of Thr-216 with main chain between Phe-31 and Asp-32. Both strands h and p are internal strands, which is usually the case for parallel β structure[24].

Maleic acid has two carboxyl groups which interact[31] and the pK$_a$ values of these groups are 1.83 and 6.07

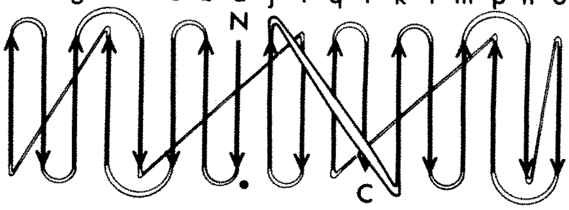

Fig. 5 Diagrammatic representation of the 18-stranded mixed β-pleated sheet structure. This diagram does not display surface topology which can be seen in Fig. 4. Strands of polypeptide chain are labelled a–r from the N to C terminus. The residue numbers at the start and end of each strand are: a (−2 → 8), b (11 → 18), c (25 → 33), d (36 → 41), e (62 → 66), f (84 → 87), g (98 → 104), h (118 → 124), i (150 → 156), j (161 → 168), k (179 → 186), l (189 → 199), m (202 → 216), n (218 → 224), o (286 → 295), p (298 → 303), q (309 → 316), r (319 → 325). The sequence of connection types according to the convention of Richardson[24] is −1, −1, −2, −3X, +1, +2, +5X, −1, +4X, +1, +1, +2, +1X, −2, −5X, +1.

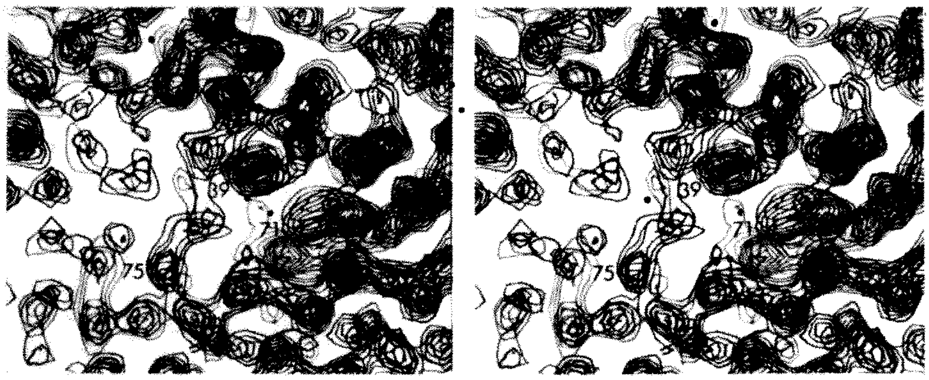

Fig. 6 Seven sections (1-Å spacing) of the electron density map in the region of Trp-39, Trp-71 and Tyr-75. The stacking of the rings of Trp-39 and Trp-71 is shown and the edge of Trp-39 is in contact with the solvent channel of the substrate-binding groove.

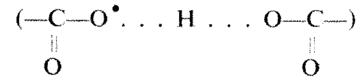
(ref. 32). Both maleic acid and the maleate monoanion[33,34] have a proton shared between two oxygen atoms



$$(\text{—}\underset{\underset{\text{O}}{\|}}{\text{C}}\text{—O}^{\bullet}\ldots\text{H}\ldots\text{O—}\underset{\underset{\text{O}}{\|}}{\text{C}}\text{—})$$

The interaction of the carboxyl groups of Asp-32 and Asp-215 probably occurs through a similar sharing of a proton. The proximity of these groups could satisfy the requirement for a protonated and an unprotonated group[26]. The pH-dependence of the DNA-reaction with Asp-215 (refs 27, 35) and the EPNP-reaction with Asp-32 (refs 29, 36), suggests that in the conditions of the modification reactions, Asp-215 has a higher pK_a ($\sim$4.5) than that of Asp-32 ($\sim$1.5). The two carboxyl groups as seen in the present crystal structure are not necessarily in the same ionisation state because there are neighbouring side and main chains which interact with the carboxyl groups in a non-symmetric manner. Various hydrogen bonding interactions occur with the Asp-32 carboxyl group which is the first carboxyl group to be deprotonated on raising the pH above 1. The oxygen, of the carboxylate group, which is hydrogen bonded to Asp-215 also interacts with main chain between Thr-216 and Gly-217; the internally buried carboxyl group of Asp-304 interacts with the opposite side of this peptide bond (see Fig. 2). Ser-35 is hydrogen bonded to the other carboxylate oxygen of Asp-32, either directly or through a solvent bridge. There are no equivalent interactions seen for Asp-215 although the side chain of Thr-218 is nearby. In addition, there is an ion-pair (Lys-308 with Asp-11) in the vicinity of Asp-304 and a conformational change brought about by rotation of the carboxyl group of Asp-304 around its $C\alpha$–$C\beta$ bond could change the ion-pair to one between Lys-308 and Asp-304. The positive charge of Lys-308 in penicillopepsin is conserved in the mammalian enzymes by having an arginine residue at this position in pepsin and chymosin[37]. The implications of these interactions which involve conserved residues in all the acid protease sequences thus far determined[30,37] must await detailed model building of penicillopepsin and a comparison with other high resolution protease structures.

Binding groove

Although we have no direct evidence in the form of difference electron density maps of inhibitor or substrate analog binding, we postulate that the deep groove which separates the two lobes of the molecule is the extended substrate binding site common to acid proteases[10,26,38]. There are three reasons for this proposal. (1) The two active site aspartic acid residues are located inside the groove and towards one end of it. (2) There is a cluster of three aromatic residues which are very close to the surface of the groove and are located in the larger lobe at distances between 8 and 13 Å from the active site. Trp-39 and Trp-71 have their ring systems stacked and one edge of Trp-39 is in contact with the solvent channel of the groove (see Fig. 6) Tyrosine-75 is also located in this region and is in contact with solvent. Chemical studies with the peptide Leu-Gly-Leu have shown that it binds to penicillopepsin, activates the hydrolysis of Leu–Tyr–NH$_2$, inhibits the penicillopepsin activation of trypsinogen and produces changes in three of the transition bands (290, 286 and 276 nm) of the CD spectrum of penicillopepsin[39]. We suggest that the binding of Leu–Gly–Leu and other activator peptides[10] in the groove perturbs Trp-39, Trp-71 (the bands at 290 and 286 nm) and Tyr-75 (276 nm) and that this perturbation on binding causes the circular dichroism spectral changes. There is only one other tryptophan residue, Trp-190, and its circular dichroism band (293 nm) does not change when activator peptides are bound to penicillopepsin. Trp-190 is buried in the hydrophobic core, inaccessible to solvent and removed from the active site region. (3) The deep groove observed in the low-resolution study of the acid protease from *R. chinensis*[7] is the site of binding of inhibitors to this enzyme. As the other acid proteases have a cleft in the molecule, it is probable that the feature we observe is the extended substrate binding cleft.

Enzymatic studies have led to estimates of the total length of the substrate binding groove of seven[40] to eight or nine amino acid residues[41]. For a fully extended substrate chain this would correspond to a length of 26–32 Å. In penicillopepsin we have estimated the length of the binding site on the N-terminal side of the scissile bond (secondary site A and primary site S$_1$ as defined by Takahashi and Hofmann[42]) and found it to be equivalent in length to a tetra or pentapeptide[43] (14–18 Å). From the length of the groove estimated on the model ($\sim$30 Å) and the circular dichroism evidence, we conclude that Leu–Gly–Leu binds in the secondary site A (ref. 43) and that this site is located in the deeper and longer part of the groove (to the right of the catalytic site in Fig. 4).

Comparison with other acid proteases

The amino acid sequence comparison in Fig. 3 shows regions of extensive homology between penicillopepsin and porcine pepsin. The overall shape and dimensions of penicillopepsin are very similar to those of the acid proteases of *R. chinensis*[7] and *E. parasitica*[8]. Insufficient information is available for a detailed comparison with the 2.7-Å structure of pig pepsin[6], but the reported tracing of the path of the polypeptide chain of pepsin[6] shows no homology to the structure we report here. Although Fruton[10] has suggested that pepsin and carboxypeptidase A have similar enzymatic mechanisms, the tertiary structure of penicillopepsin is distinctly different to that of carboxypeptidase A, which has an extensive arrangement of 8 strands in mixed parallel and anti-parallel β-sheet conformation[44]. We have compared, visually, the polypeptide chain folding of penicillopepsin reported here to those of the acid proteases from *R. chinensis* and *E. parasitica*. The three structures are in close agreement, strengthening the argument that the porcine pepsin structure will be found to be similar.

We thank Mr S. R. Jones for preparation of penicillopepsin and for crystal growing, Dr G. Lenhert for his system of programs for the FACS-1 diffractometer[45], and Dr M. G. Rossman for the phasing program used. This work was funded by the MRC of Canada.

letters to nature

A conspicuous globule in the Southern Coalsack

THE Southern Coalsack is the finest dark nebula in the Southern Milky Way. At the Royal Observatory, Edinburgh, in October 1976, we studied two photographs taken with the SRC 1.2-m Schmidt telescope (a Unit of the Royal Observatory, Edinburgh) at Siding Spring Observatory, Australia. Centred at α (1975) = 12h 45min, δ (1975) = −63°01′, they show the whole of the Coalsack in all its beauty. The blue plate (Fig. 1) was a 60-min exposure on a hydrogen-sensitised IIIaJ plate, taken through a 2-mm Schott GG395 filter; the near-infrared plate was a 60-min exposure on a water-hypersensitised IN plate, taken through a 4-mm RG715 filter. These plates were taken as part of a more comprehensive study of the Southern Coalsack; this note represents a pilot study of how much can be learned by simple star-counting techniques. Visual inspection of these plates confirms the earlier conclusions[1–3] that the Southern Coalsack is basically a thin obscuring sheet with an average total visual absorption $A_v = 1.2$ mags. Rodgers[1] derived the distance from the Sun to the Coalsack to be 175 pc.

A globule is a roundish, sharply bounded dark nebula with an angular diameter of a few minutes of arc, seen projected as a 'Loch im Himmel' (William Herschel) against a star-rich background. The present pair of Schmidt photographs show a large number of potential globules. A general catalogue is being compiled of globules identified on SRC Schmidt plates of the Southern Milky Way. (This search is being undertaken at Siding Spring by Drs W. M. Goss, R. Manchester, T. G. Hawarden, A. J. Longmore and I. J. Danziger.)

Westerlund was the first to draw attention to the numerous globules in the Southern Coalsack. His original conclusions have been confirmed and extended by Tapia[4]. The most obscured (star-poor) regions in Tapia's Survey are the regions Tapia I and Tapia III. In our survey we have catalogued 27 globules and patches of dense obscuration associated with the Coalsack, some of which are identified in Fig. 1. The first six objects in our catalogue are the globules listed in Table III of Tapia's paper. The densest and most nearly perfect of these globules is the second one in Tapia's list, located at α(1975) = 12 h 30.0 min, δ(1975) = 63°37′ in the region Tapia III. It has an angular diameter of about 6 arc min (0.3 pc). We will refer to this as globule 2.

A comprehensive study of these globules awaits *inter alia* the establishment of standard magnitude sequences in B, V, R and I, to $V = 22$. Useful information on globule 2 has been obtained, however, from inspection of the two available plates. At the suggestion of Dr R. D. Cannon, and with the assistance of Mr R. D. Eberst (both of the Royal Observatory, Edinburgh) a modified Zeiss Blink Comparator has been used to make a fairly complete study of the optical properties of globule 2 by applying simple star-counting methods. The comparator has been modified by J. M. Allen to incorporate a closed circuit TV system similar to that designed and built by J. G. Bolton at ANRAO, Parkes, N.S.W. In addition to the blink facility, the images on a pair of plates may be viewed on the TV monitor simultaneously or separately, side by side or superimposed, or in split-screen modes, by using the appropriate 'wipe' or 'fader' facilities. In the present case the infrared and the blue plates were inspected in a nearly superimposed mode, with the infrared images appearing as black dots and the blue images as white dots in the TV display (Fig. 2).

Beyond the outer limits of globule 2 each star shows both red and blue images, generally right up to the rather sharp outer edge of the globule at about 3 arc min from its centre, measured on the blue (J) plate. In the annulus lying between 3 and 1.6 arc min from the centre of the globule, 37 stars have red images without blue companions, and only four stars in this annulus have faint blue images. There are no stars visible in either colour within 1.6 arc min of the globule centre. The star counts were done from polaroid photographs of the TV display. These simple observations show that the dust in globule 2 is highly concentrated towards its centre. Similar counts were made in a comparison field in a star-rich region 17 arc min south of globule 2. In this field 186 stars had images on the infrared plate, and of these 170 stars also appeared on the blue plate, in an annulus of radii 1.6 and 3 arc min.

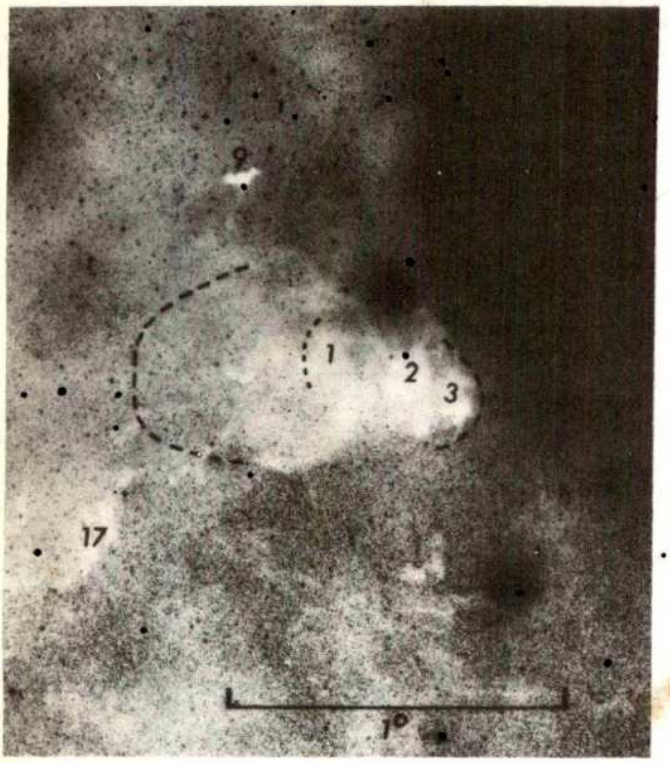

Fig. 1 Part of the Southern Coalsack, reproduced from a deep IIIaJ plate taken with the U.K. 1.2-m Schmidt telescope at Siding Spring. Globules 1, 2 and 3 in Tapia's list are numbered. α Crucis is shown on the right (west) of the print. The long-dashed curve indicates the approximate boundary of the HI absorption observed by Kerr *et al.*[8], and the short-dashed curve shows the eastern boundary of the formaldehyde absorption observed by Brooks *et al.*[9].

An approximate minimum dust mass for globule 2 can easily be derived from the star counts using the methods described by Bok, Cordwell and Cromwell[5] and in the doctoral thesis of Dickman[6]. We base our calculations on the log $A(m)$ against m curves in the blue and near infrared shown by Tapia[4]. These curves were derived from stars between the 12th and 16th magnitude, but the limiting magnitude of the blue Schmidt plate is at least B]22. Star-count data to 21.0 mag (ref. 7) indicate that the slopes to be used in our calculations should be approximately two-thirds of those derived by Tapia. Comparisons of the near-infrared star counts in the annulus round the globule 2 and in a comparable area in the comparison field yield a value of the average absorption in the near infrared (about 8,500 Å) $A_I = 2.7$ mag. Corresponding values for A_B and A_V are $A_B = 6.5$ mag, $A_V = 5.0$ mag. The value of A_B is roughly confirmed by the presence of four stars in the annulus which have faint blue images. This is about the number we would expect for $A_B = 6.6$ mag. The values quoted apply strictly only to the annulus between 1.6 and 3 arc min from the centre of the globule.

A minimum dust mass for the entire globule can be obtained by applying the above values to the whole of the globule. The mass thus derived underestimates the total contribution from the core, for which we know only that A_V and A_B must be greater than the values given above for the outer ring. The derived minimum dust mass is $0.05M_\odot$. Using a factor 200 to proceed from the dust mass to the total mass of dust and gas (presumably mostly molecular hydrogen, H_2), we derive an approximate minimum mass of $10M_\odot$ for globule 2. This is a minimal value since we have not been able to penetrate the 1.6-arc min diameter core of this globule, which may be quite massive, possibly as high as $25M_\odot$. The estimate of the minimum total mass should be halved, however, if the dust to gas ratio in this region is assumed to be 1 : 100. We note that the total absorption A_V enters linearly into the formulae from which the total mass is derived.

Kerr, Hawarden and Bowers[8] searched for HI self-absorption in 19 regions in the Coalsack, and found it only in the region of globule 1, 2 and 3. The neutral hydrogen peaks over globules 1 and 2 and tails off for 35 arc min east of globule 1. In the outer edges of the HI distribution the optical absorption is much lower than in other regions where no HI absorption was seen. Brooks, Sinclair and Manefield[9] have observed the distribution of OH 1,667-MHz emission and formaldehyde 4,830-MHz absorption over the complex. The OH distribution resembles the HI distribution (and hence the optical absorption distribution shown in Fig. 1) while the formaldehyde was detected only in the regions of highest dust density, outside of which it falls off steeply on all sides. Sinclair and Brooks[10] estimated the diameter of the formaldehyde cloud in globule 2 to be 8 arc min, very similar to the optical diameter found from our photographs of globule 2 and its close neighbours.

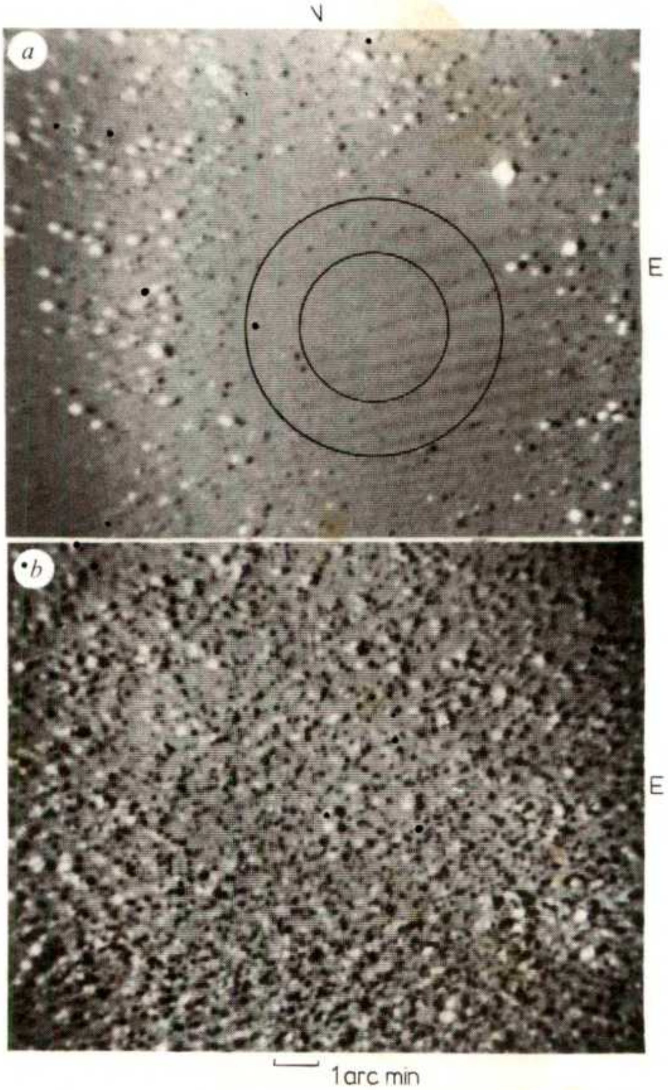

Fig. 2 TV monitor display of *a* globule 2, and *b* the comparison field. Images from the blue plate are shown in white; images from the near infrared plate are shown in black.

Radio observations are beginning to yield much additional information on the physical conditions in the complex around globule 2. A team from Queen Mary College, London[11], have used the 3.9-m Anglo–Australian telescope to observe the 2.6-mm line of CO at six points. Their preliminary results show that the CO emission also peaks over globule 2, for which they derive a mass of several solar masses and kinetic temperatures between 6 and 16 K. Dickman's results for globules accessible from northern latitudes would suggest probable numbers of ^{13}CO molecules in globule 2 of between $N_{13} = 10^{16}$ and $N_{13} = 2 \times 10^{16}$. His formula for the mass of the molecular hydrogen in g cm^{-2} is: N_{mass} (g cm^{-2})

$= 2 \times 10^{-18} \times N_{13}$. From the widths of the lines in the radio spectrum it should also be possible to derive the velocity dispersion of the CO molecules and any rotation of the globule, if present, should be detectable to within 0.1–0.2 km s^{-1}.

The studies of globules by Martin and Barrett[12] and by Tucker *et al.*[13] show that globules are most likely to be gravitationally bound and in a state of collapse. The smaller ones among the large globules, such as Barnard 335, have radii of the order of 0.3 pc and masses of about 25 $M_\odot$. Larger objects in this class, such as Barnard 5, have radii of the order of 1.2 pc and masses as high as 800 $M_\odot$. Globule 2 ranks as being smaller and a little less massive than Barnard 335. The smaller ones will probably collapse into single or more likely multiple stars, whereas those of higher masses may collapse into modest star clusters. Globule 2, as well as most other globules in the Southern Coalsack, is probably on the verge of collapsing into a single or multiple star. The time required for collapse into a protostar (or a modest protocluster) is probably < 1 Myr.

We thank the staff of the UK Schmidt Telescope Unit for providing the plates used in this study.

Periodic fadings in VHF radio-satellite transmissions during the solar eclipse on 23 October 1976

THE localised time-dependent cooling action of the lunar shadow during an eclipse may generate gravity waves at ionospheric heights[1,2]. The bow wave thus formed would be detected at great distances from the eclipse path. Experimental data in the northern hemisphere from the eclipse on 7 March 1970, indicated the presence of gravity waves in the F-region, deduced from the incoherent backscatter technique[3], vertical incidence soundings[4], and recordings of the Faraday rotation angle of VHF transmissions from geostationary satellites[5]. The detected travelling ionospheric disturbance (TID) had the horizontal phase velocity of 400 m s^{-1} (ref. 4) and 620 ± 120 m s^{-1} (ref. 5). TID was reported to travel north to south[4], or 279 ± 25° east of north[5]. We report here our observations of large-magnitude periodic fadings during the eclipse of 23 October 1976, which indicate that the eclipse is associated with generation of wave disturbance affecting radio-satellite transmissions in the upper VHF. The waves had a 40-km wavelength, and propagated from north to south with a velocity of 556 m s^{-1}.

It seems that no experiment has been conducted on the effect of the solar eclipse on the amplitude of radio transmissions from non-synchronous satellites. This was mainly due to the limited number of orbiting satellites used in previous scintillation studies. Thus, the probability of coincidence of an eclipse and a satellite pass was small. Our results are based on amplitude recordings of VHF radio signals from six U.S. Navy Navigational Satellites (NNSS) transmitting at a frequency of 149.988 MHz, and D2-B satellite (catalogue No. 8332) transmitting at a frequency of 136.740 MHz. NNSS and D2-B had orbit inclinations of 90 and 37°, respectively. The recording station was at Brisbane (27.5°S, 152.9°E geog. lat. and long., and 37.2°S invar. lat.).

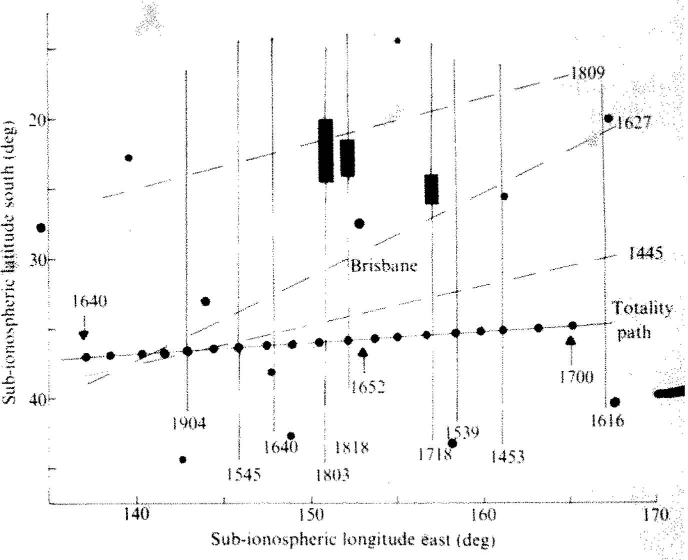

Fig.1 Sub-ionospheric orbits of NNSS (—) and D2-B (– – –) satellites during the solar eclipse on 23 October 1976. The first periodic fadings (vertical bar) were recorded during a NNSS pass at 1718 LT after the time of the closest approach of totality at 1652 LT. Arrows show the central positions of the eclipse at different local times.

The path of eclipse totality on 23 October 1976, ran south of the Australian continent between about 1600 and 1700 LT (150° EST). It was possible to record a relatively large number of satellite passes during the eclipse period, using radio transmissions from the seven orbiting satellites. Figure 1 shows the sub-ionospheric orbits for NNSS and D2-B at 400-km altitude. The satellite passes at 1445, 1453, 1539, 1545, 1616, 1627 and 1640 LT (times of the predicted nearest approaches) did not show any scintillation activity. A NNSS pass at 1718 LT revealed pronounced periodic fluctuations of a large magnitude (3 dB peak-to-peak) superimposed over normal, slow variations in amplitude (Fig. 2). The disturbed region was north of Brisbane (vertical bar in Fig. 1). Assuming that the disturbance occurred at the point of closest approach of totality at 1652 LT, the velocity of propagation of the waves is 556 m s^{-1}.

The following NNSS passes at 1803 and 1818 LT indicated the presence of periodic fadings of an unusually large magnitude (5 dB peak-to-peak in Fig. 2), confined to the region further north of Brisbane (Fig. 1). The periodic fadings were absent during a pass at 1904 LT. A D2-B pass at 1809 LT from south-west to north-east did not reveal any periodic fluctuations (Fig. 1), indicating that the wave-front was directed more towards the geographic north than east–west, since radio fadings are enhanced in the direction of the steep ionisation gradient generated by the passage of a periodic disturbance. It should be also noted that the largest periodic fadings were recorded about the time when the eclipse terminated. This may be associated with the enhancement of TIDs at the end of the eclipse due to an interference effect of the waves generated at various positions of the totality. The possibility of such enhancement was suggested in association with the eclipse on 7 March 1970 (ref. 1).

The disturbances shown in Fig. 2 had a typical period of about 10 s, which corresponds to a 40-km wavelength at ionospheric heights. This is considerably smaller than the wavelengths found from the ionospheric experiments conducted during the 1970 eclipse. For example, the total electron measurements[5] indicated a 20-min period of the disturbance, which corresponds to a wavelength of about 700 km. This difference may be due to the various spectral characteristics of the techniques used for detection of ionospheric fluctuations; the total electron and satellite scintillation methods tend to indicate long and short scale sizes of the disturbance, respectively. From this, it seems that the eclipse generates TIDs with a number of wavelengths ranging from about 40 to 700 km.

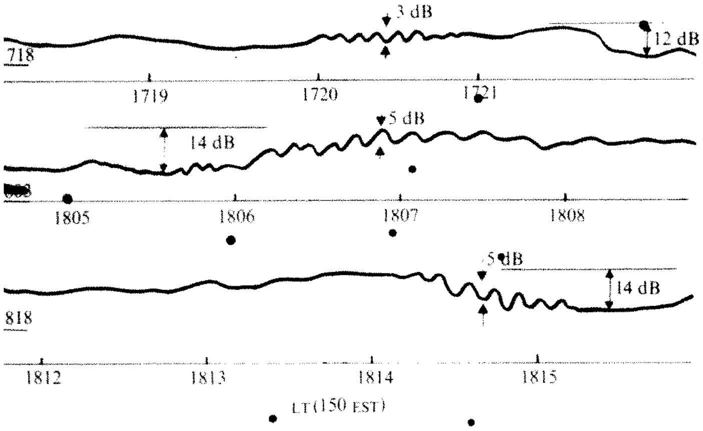

Fig. 2 Amplitude structures of periodic fadings in VHF radio-satellite transmissions during the eclipse period.

The distinct and prolonged periodic fadings (Fig. 2) are an unusual feature of the radio-satellite experiment conducted over several years at Brisbane. Amplitude records obtained from 150 satellite passes in October, 1976, indicated the presence of periodic fadings in 3% of passes. The periodic fadings recorded at other times than the eclipse period had a less well-defined quasi-sinusoidal structure and their magnitude was $\leqslant 3$ dB peak–peak. Also, their duration was limited to one satellite pass only, unlike the events shown in Figs 1 and 2, which were recorded during three consecutive satellite passes.

Electrons and positive ions in an auroral arc

Two new types of British sounding rocket, a Skylark 12 and a Fulmar, were launched from Andøya in northern Norway, on 21 November 1976, in an experiment to study the particle streams and plasma waves associated with an auroral arc. We report here the first results obtained from channel multipliers and electrostatic analysers carried on the Skylark 12 (designation SL 1422) to detect electrons in the range 0.5–25 keV, and positive ions of 0.5–25 keV per unit charge. We believe that the results are unique and constitute the first detailed comparison of positively- and negatively-charged particles in the region of an auroral arc. They have been made possible by the combined advantages of high altitude (715 km), which enables ions to be studied before absorption in the atmosphere, long range (780 km), which allows a complete traversal of an auroral structure, and new analysers, which extend the dynamic range of measurement.

Spectrograms of positive ions and electrons taken from near the middle of the flight are shown in Fig. 1. In this period the rocket, travelling northwards, left the diffuse aurora to the south of the arc to enter at 265 s the intense stream of electrons that produced the luminous east–west curtain of the visible arc. The period shown also encompasses the rocket's emergence at 360 s into a region of sub-visual aurora to the north of the arc.

We note first that the arc is characterised by relatively high electron intensities and energy spectra with a pronounced peak whose position varies within the arc between 2 and 9 keV. We note also the marked anticorrelation between electron and ion intensities during the transition between the diffuse aurora and the arc. The anticorrelation does not persist far into the arc: between 305 and 330 s, although there is little obvious change in the electron intensity, the ion intensity rises to form a spectrum with a broad peak around 6 keV, a minimum near 2 keV, and a tail rising towards low energies. This ion spectrum is unlike those measured between 150 and 250 s which are approximately Maxwellian with a most probable energy of 10 keV. To the north of the arc after 360 s the most probable energy of the ions is 3 keV, and the electron spectrum has a power-law form with intensities decreasing towards higher energies. (Unfortunately, in the presence of unremoved telemetry noise, only some of these features are readily discernible in the black-and-white spectogram of Fig. 1.)

We offer the following preliminary interpretation of these results based on conclusions drawn from earlier lower-altitude flights about the mechanism for electron acceleration in auroral arcs[1,2]. To the south of the arc we suppose the electrons and ions to be scattered without significant acceleration from their source plasma, the plasma sheet of the magnetosphere, where electron and ion temperatures correspond to 2 and 10 keV, respectively. The particles forming the arc are from the same source, but in this case the electrons are accelerated during precipitation by the equivalent of a potential difference that fluctuates rapidly about a most probable value indicated by the position of the peak in the spectrum. The fluctuations are invoked[1,2] to account for the breadth of the peak on the low-energy side; the breadth on the high-energy side is simply a consequence of the finite temperature of the source plasma. Ions, being subject to the same potential differences, are retarded and reduced in intensity when electrons are accelerated. This would account for the anticorrelation near the southern border of the arc. We suggest that the increase in ion intensities near the centre of the arc, where electrons still seem to be accelerated, is an example of an occurrence predicted earlier[3], namely, that at times the effective potential difference could fluctuate enough to reverse in sign temporarily and apparently accelerate ions and electrons simultaneously. The peak in the ion spectrum, being sharper than that of the Maxwellian spectra to the south, is consistent with acceleration taking place at this time. The facts that the ion peak is broader than the electron peak and the ion intensity is less enhanced than the

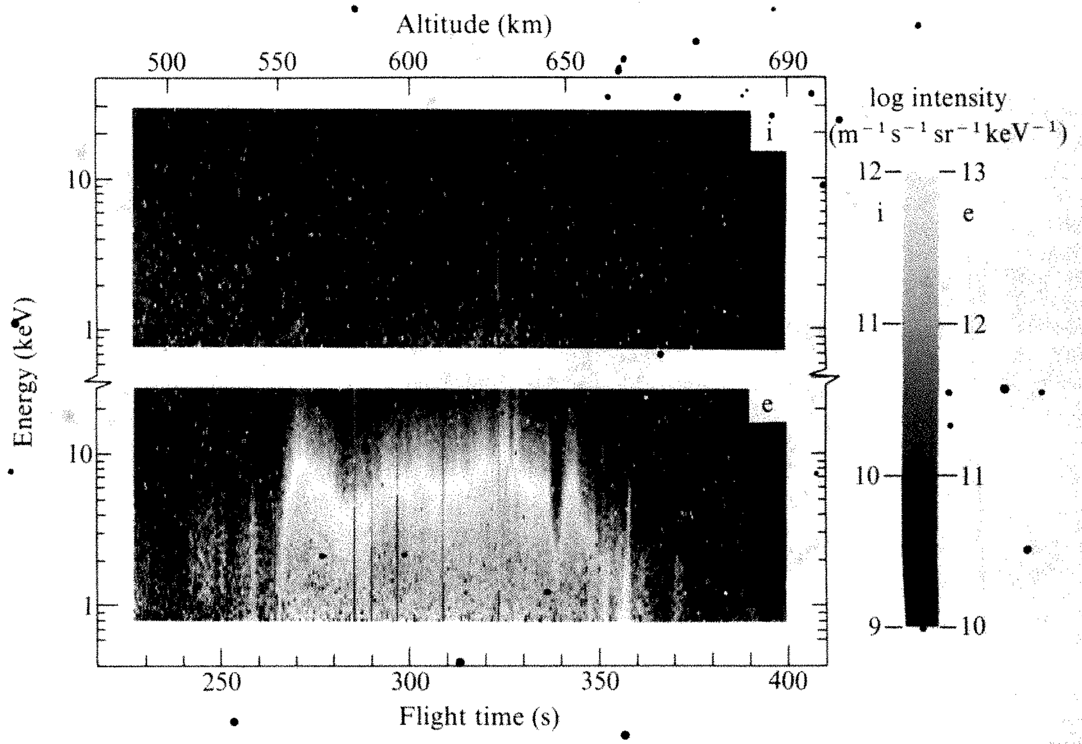

Fig. 1 Positive-ion (i) and electron (e) spectrograms from SL 1422 launched at 2115 UT on 21 November 1976. The intensities were measured at pitch angles in the range 30–40°.

electron intensity indicate a broader distribution of energy gain for the acceleration of positively-charged particles. North of the arc the electrons and ions are of lower energy than those to the south, and the electron spectra are different in form. This supports the suggestion made previously, based on shorter-range flights[4,5], that auroral arcs are phenomena occurring at the boundary between the plasma sheet and high-latitude magnetotail regions of the magnetosphere.

Speckle image reconstruction of solar features

SPECKLE imaging is a process which permits recovery of diffraction limited resolution from atmospherically degraded astronomical images. We describe here the application of this new process to the reconstruction of solar surface features with resolution approaching the telescope limit, despite severe atmospheric blurring in the original data.

Speckle imaging has evolved from speckle interferometry, which has been used to measure stellar diameters[1] and binary stars[2] to an angular resolution of 0.025 arc s and has yielded evidence of sub-arc s surface detail when applied to solar images[3,4]. In speckle interferometry only image autocorrelations are obtained, restricting information recovery to centrosymmetric detail. In speckle imaging, true diffraction limited images of extended objects can be reconstructed without requirement of a reference star in the field.

The data-taking requirements are identical for both imaging and interferometry: a series of short exposure, narrow pass-band, highly magnified images are recorded on film. For most low light level astronomical objects, an image intensified camera is used, though for solar work no intensifier is required. The conventional procedure for processing speckle interferometry data is to Fourier transform individual images and sum their power spectra. In the imaging process, the phase in the Fourier transform of each frame is encoded in the form of point-to-point phase differences. This is performed in two dimensions by calculating the shifted complex product of the transform. The results for each frame are summed, yielding averaged quantities $\langle A(u,v)\rangle$, in the form

$$\begin{aligned}\langle A_u(u,v)\rangle &= \langle I(u,v)\, I^*(u+\Delta u,v)\rangle \\ \langle A_v(u,v)\rangle &= \langle I(u,v)\, I^*(u,v+\Delta v)\rangle\end{aligned} \qquad (1)$$

where $I(u,v)$ is the image Fourier transform and the two averages encode the phase in the u and v directions, respectively. The shifts, Δu and Δv, must be small compared to the resolution element in the object transform.

Each of the components in equation (1) can be expanded in the form

$$\begin{aligned}\langle A(u,v)\rangle \simeq & |O(u,v)|^2 \exp\{i[\Phi(u,v)-\Phi(u+\Delta u,v)]\}\times \\ & \times\langle |T(u,v)|^2 \exp\{i[\Psi(u,v)-\Psi(u+\Delta u,v)]\}\rangle\end{aligned} \qquad (2)$$

where $O(u,v)$ is the object Fourier transform, $T(u,v)$ is the atmospheric transfer function, and $\Phi(u,v)$ and $\Psi(u,v)$ are the phase in the object transform and the atmospheric transfer function, respectively.

The transfer function term in equation (2) has an expected value whose phase approaches zero (since the atmospheric phase fluctuations are a stochastic, zero mean process) and whose amplitude approaches the diffraction limited transfer function usually obtained in conventional speckle interferometry. For reconstruction, the relative phase at any point in the transform is calculated by summing the phase differences between that point and an arbitrary reference point over a multiplicity of paths, which greatly reduces the effects of noise

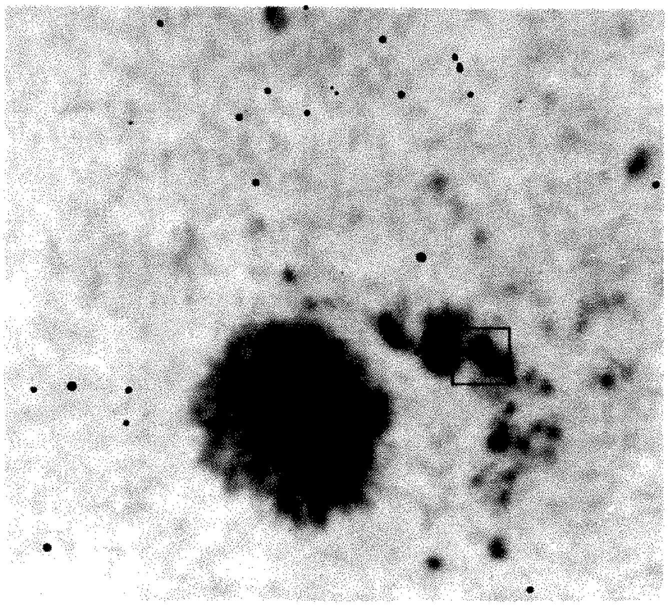

Fig. 1 Photograph of the Sun showing the region processed.

and bad data points. Finally, the output image is obtained by Fourier inversion of the resulting phase and amplitude distribution. This procedure is based on an algorithm suggested by Knox and Thompson[5] and developed and demonstrated for two-dimensional extended, continuous tone objects with simulated atmospheric degradation by Nisenson *et al.*[6]. This process is unrelated to the technique reported by Lynds *et al.*[7], which is applicable only to small objects, close to the telescope diffraction limit in extent. It is also unrelated to the large class of image-processing algorithms in which an inverse impulse response is estimated and applied to restoration of the image.

The photographs processed in this experiment were obtained from Dr J. W. Harvey of Kitt Peak National Observatory and were taken at the 24-inch vacuum solar telescope. The passband was 10 nm centred on 500 nm and the exposure time was $\sim 1/100$ s. At the magnification used, the telescope diffraction limit occurs at a spatial frequency of about 35 lines per mm, well within the transfer characteristics of the Kodak 5460 film. Thirty-two frames were suitable for processing. Figure 1 is a typical frame covering a 2-min square field. Only the indicated 8 × 8-arc-s area, which included a dark feature, was processed. Note the presence of irregular fringe-like interference features in part of the image. These vary randomly from frame to frame, and are coherent phenomena induced by atmospheric turbulence.

On each frame the subarea was scanned and digitised as a 128 × 128 array centred on a selected feature. A 128 × 128 array was chosen to allow two samples per resolution element and to restrict the processed region to an area smaller than the expected isoplanatic patch size. The isoplanatic patch is determined by the angle over which the atmospheric point spread function remains highly correlated.

The digitised frames were then processed as we have described. Each frame was digitally Fourier transformed using an FFT algorithm and, after phase coding, the transforms were added together and the phase reconstruction algorithm applied. The phase and amplitude distributions derived from the averaging process are then retransformed to obtain an image.

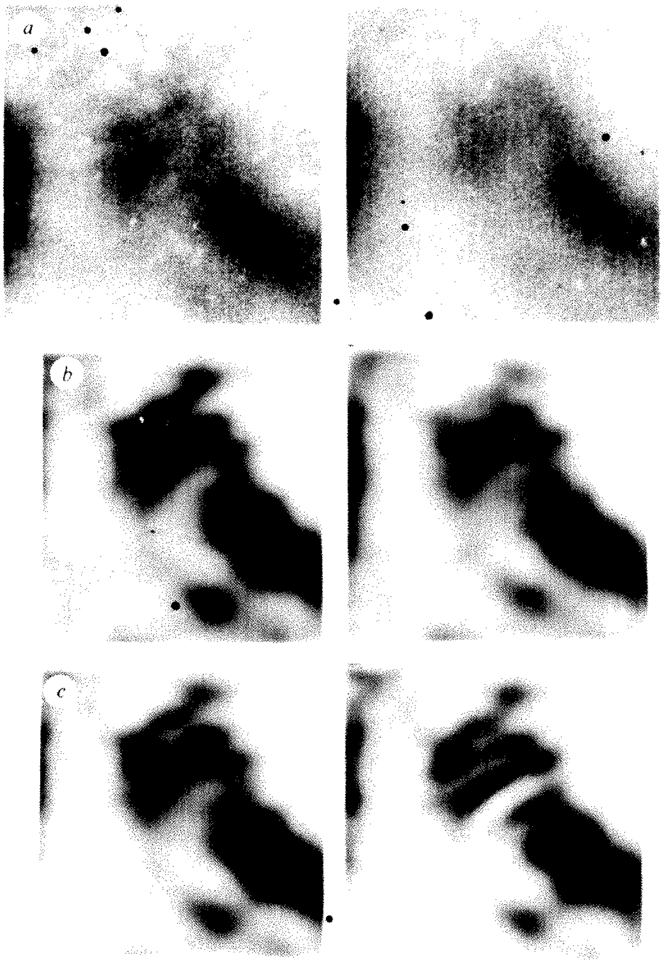
Figure 2 includes two typical input frames after scanning and redisplay. The seeing limit varies from frame to frame and from region to region in the full field (see Fig. 1); however, the average is about 2 arc s, which is 12 times the telescope diffraction limit.

Separate reconstructions produced from 4, 8, 12, 16, 24 and 32 frames show development of small features with progressively increasing sharpness. Reconstructions produced from sequences of frames selected to be free of defects were also nearly identical to those obtained without selection. Figure 2*b* shows two independent 12-frame reconstructions, demonstrating that the essential features are real. Figure 2*c* shows 24-frame and 32-frame reconstructions. The resolution in the final processed image is better than 0.4 arc s and some features such as the bright lanes in the filamentary structure near the centre of the image may be closer to 0.2 arc s, the telescope limit. The resolution (0.4 arc s) is comparable with that obtained in the Stratoscope balloon experiments.

Processing a smaller subarea may have the effect of increasing the rate of convergence to a diffraction limited image if isoplanatism is a problem. The size of the isoplanatic region for solar observations can only be estimated, and a processed area as large as 8 × 8 arc s may not quite converge to the diffraction limit with only 32 frames.

The processed subarea contains a feature which, from the large scale photograph, would be described as a medium-sized pore. In the reconstruction, the region near the centre of the frame breaks up into a number of dark, parallel, elongated features reminiscent of penumbral structure, while the region below it retains the appearance of a typical pore. The penumbra-like structure is approximately radial to a large nearby spot although it is not connected to it. At least two features looking like very small pores approximately 0.7 and 1.0 arc s in size are detached from the primary structure except for a dark lane. Other dark lanes are evident in the picture, the longest extending about 3 arc s.

Fig. 2 *a*, Two typical unprocessed frames (8 × 8 arc s) used in producing the reconstructions after scanning and redisplay; *b*, two reconstructions produced from independent 12-frame subsets of the data; *c*, 24-frame (left) and 32-frame (right) reconstructions. Resolution is approximately 2.0 arc s in the unprocessed frames and approximately 0.4 arc s in the processed frames.



The lighter regions of the reconstruction show evidence of photospheric granulation. This is particularly interesting because there is virtually no evidence of this structure in the original digitised frames, partly because of the limited dynamic range of the scanning instrument, which was set to scan optimally the spot region. The original negatives of the reconstructions show that the entire photospheric region is covered by granules, the smallest of which are less than 0.5 arc s in diameter.

To obtain wide field reconstructions, individual isoplanatic regions must be processed independently and combined in a mosaic. This is a lengthy process that requires large amounts of computer and scanner time. To solve this problem, an optical processor that performs an analog of the digital process is now being developed[8]. Optical processing allows encoding of the phase and direct summation of the individual transforms. The output of the processor is a single frame that is scanned and digitised for computer reconstruction of the final image. With this system, a number of contiguous isoplanatic regions can be processed in parallel, yielding images of relatively large areas at once.

In conclusion, we would like to point out that the ultimate resolution of the process is the diffraction limit of the telescope, independent of the actual seeing conditions. Data taken on the 60-inch solar telescope at Kitt Peak, for example, could display features down to 1/15 arc s, and this can be extrapolated to even larger apertures.

Long term solar activity forecasting using high-resolution time spectral analysis

SOLAR activity as measured by sunspot number has been carefully observed since 1749. It seems to have an 11-yr cycle which has been identified as a 22-yr magnetic period with every other 11-yr cycle having a reversed average solar magnetic field. As the amplitude and frequency of the cycle varies slowly with time it has become a point of interest to determine if sunspot activity variation is regular and constant over long periods of time. If it is constant, then it should be possible to make predictions based on historical observations. I show here that the monthly sunspot record (1749–1975) is represented by a Fourier Series, using the spectral analysis method of A. Paul. By evaluating the series, a forecast indicates that the next solar cycle began in December 1976, and will peak above 100 near 1982.

Eddy[1] has pointed out that solar activity may have been greatly different during the Maunder Minimum (a period of very low sunspot activity between 1645 and 1695) than has been generally assumed. For example, Schove[2] relied upon the assumption of nine cycles per century to identify solar maxima back to the fifth century BC. Eddy discounted Schove's estimates of the solar maxima magnitudes during the 1600s as systematically high, noting that the magnitudes were sometimes based on "auroral counts and other unspecified data". Eddy stated "the present cycle of activity may be unusual if not transitory".

On the other hand, Wolff[3] discussed physical processes within the Sun from which it is reasonable to expect long-term persistence of discrete line spectra in the sunspot activity record. He has developed a rigid and differential rotation model whose modes have beat frequencies which are mathematically related to each other. Using only two adjustable frequencies in the model, he predicted 20 of the 25 periodicities observed in the sunspot data by Cole[4] and Currie[5]. The longest period found by Wolff is 178 yr. He considered the difference between the value of 178.0 yr and the 190-yr period found by Cole[4] to be insignificant since the uncertainty[3] in an estimate of a frequency present in a record of length T is commonly given as $\pm 1/(4T)$. Cohen and Lintz[6] have used a 179-yr periodicity, with several other periodicities, to produce a prediction of solar activity to the year 2050. (Of course, an extrapolation of their model backwards in time would not produce the Maunder Minimum, particularly since they use a d.c. component of 47.4 smoothed sunspots in their model.)

Several methods for analysing spectra have been applied to the sunspot record. Cole used the fast Fourier transform (FFT) to analyse the autocorrelation function and the solar cycle phase data of Schove and obtained the power spectral density as a smooth continuous function of frequency. Both Cohen and Lintz, as well as Currie, used the maximum entropy method (MEM) to find the smooth continuous power density function. The FFT and MEM methods estimate the frequency of a suspected spectral line at the point of peak power.

I re-examine here the sunspot record from 1749 to 1975 using a high-resolution spectral analysis to determine the frequencies of the periodicities, and the amplitude and phase of each line. The analysis is performed with 2724 monthly sunspot values given by Vitinskii[7] and by *Solar Geophysical Data*. The algebraic sign of alternate cycles' sunspot numbers is negative to conform to an assumed 22-yr magnetic reversal cycle.

My analysis is an extension of a method developed by A. Paul[8], which is a very accurate and sensitive method for determining frequencies, amplitudes and phases of unknown lines in a spectrum consisting of both broadband noise and discrete lines. Paul's method differs from conventional FFT methods in that it does not assume that frequencies will be uniformly spaced. The time shift theorem ($\Delta\varphi = 2\pi f \Delta t$) is used to determine the unknown frequencies from the change of phase between the periodogram analysis of segments of the data separated in time.

My analysis uses the additional step of subtracting the waveform corresponding to the approximately known lines in the data, following by iteratively solving for closely spaced lines. The analysis applied to the sunspot record obtains resolution of closely spaced lines having a beat period ($1/\Delta f$) of $1{,}045 \pm 200$ yr. The accuracy of each frequency is more a function of the white noise within the filter bandwidth used in the analysis than of the record length. In this case, the frequency uncertainty is estimated to be $\pm 1/(20T)$ rather than the commonly quoted $\pm 1/(4T)$. The success of the line resolution just mentioned results from the signal-to-noise ratio (line amplitude to Gaussian noise within the bandwidth) of about 25 : 1.

The model is composed of more than 40 lines (Fig. 1) which were determined using more than 100 iterative solutions for one line at a time with all the other lines subtracted from the data. The s.d. of the residuals is 17.0 (unsmoothed monthly sunspots), which is an indication of white noise. Assuming it is uniformly distributed in frequency, the noise within the bandwidth near each line is about 0.6. This has been confirmed by spectral analysis of the residuals. The effect of the noise is difficult to determine; however, the noise certainly degrades the accuracy of the line parameters.

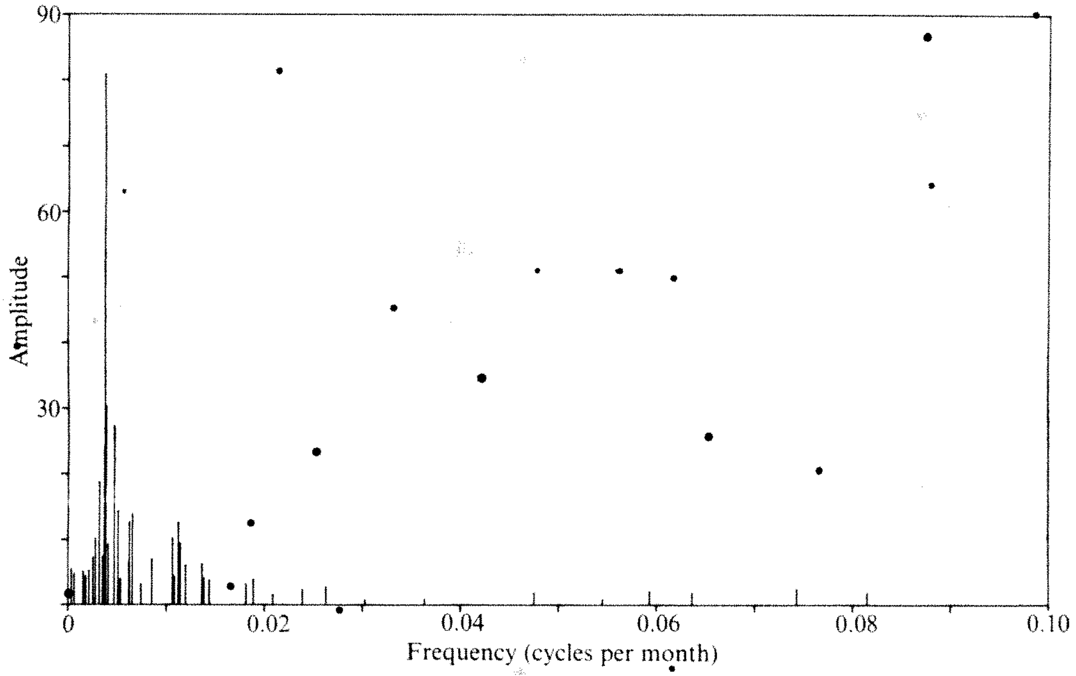

Fig. 1 Spectral lines determined from 227 yr of sunspot data.

The summed Fourier series corresponding to the lines in the model is plotted with the monthly data record in Fig. 2. The series is evaluated beyond the data record at both ends to provide a forecast of future and an aftcast of past solar cycles. Note the striking agreement between the model and observations made between 1740 and 1975.

The fact that the summed series fails to fit the data as accurately in the first and last cycles as in the central cycles may be an artefact of the data window or it may indicate changes in the physical processes of the Sun, for example, changes in the oscillation mode excitations. Figure 3 extends the model sunspot numbers back to 1000 AD and compares with the ^{14}C level given by Suess[9]. The model fails to reproduce the Maunder Minimum, but does show a 1000-yr period envelope, as discussed by Eddy. The closely spaced lines with periods of 21.62, 22.12 and 22.55 yr form a triplet with a beat period of about 1045 yr, having maxima (1112 and 2155 AD) during the same centuries as mentioned by Eddy (about 1175) but a minimum (1724 AD) later than Eddy's (1500–1714 AD). The triplet's minimum is not midway between the adjacent maxima due to the particular phase relationships between the three lines.

Although these results are purely empirical, amounting to data fitting, the stability of the solution and the

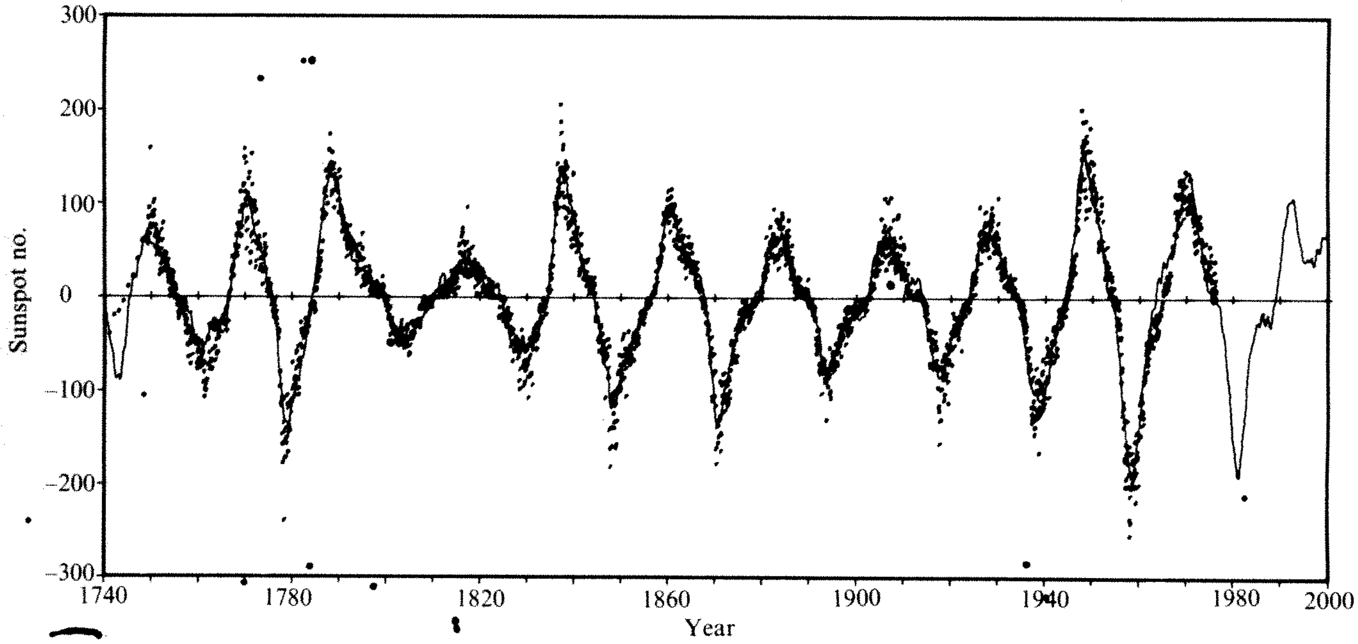

Fig. 2 Observed monthly sunspot numbers (●) and Fourier series model (smooth curve).

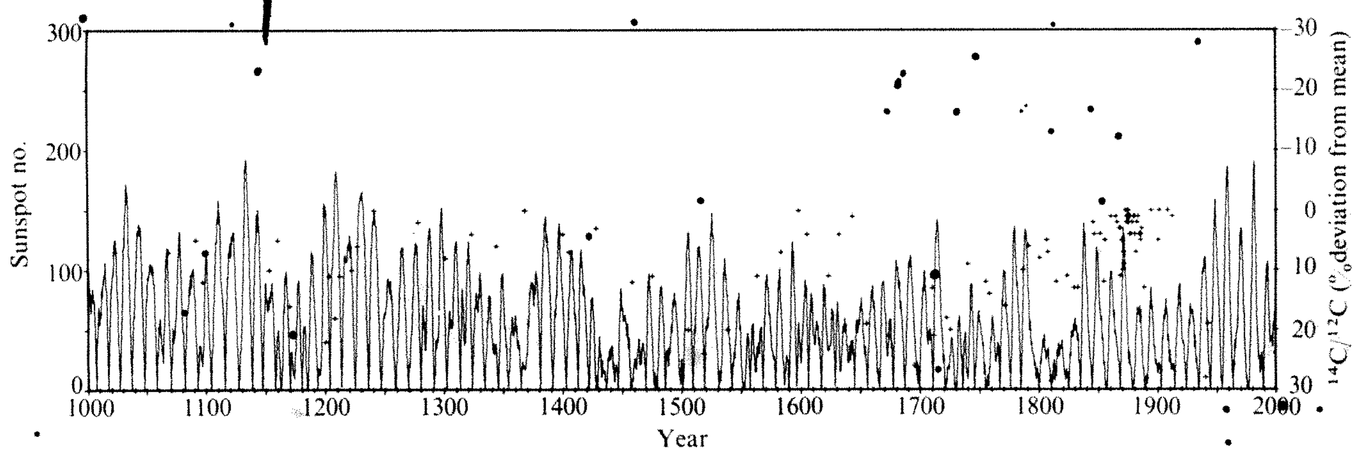

Fig. 3 Fourier Series sunspot model (smooth curve) and ^{14}C : ^{12}C ratio (+, using an inverted scale).

accuracy of the predictions may be an indication of whether Wolff's mode model is correct. My results show that there are lines in the sunspot record as indicated in Wolff's theory. The modes are long-lived, but may persist for centuries instead of millennia. This latter conclusion can be drawn if we attribute the spectral line model's failure to display correctly the Maunder Minimum to changes in physical processes in the Sun.

One area of possible improvement in the analysis is in the choice of data to represent solar activity. Eddy, Wolff and others have used sunspots, which have been counted for a long time. The noise level in the sunspot data (s.d. of 17) is about as expected, however, considering that sunspot groups are arbitrarily assigned a value of ten spots. Another index of solar activity, such as sunspot area or magnetic field intensity, may be a better quantitative measure. Seventy-five yr of high-quality data might yield better results than spectral analysis of 200 yr of lesser quality data.

The fit (Fig. 2) to the sunspot record between 1750 and 1975 is good enough to merit a forecast a few years into the future. Using the zero crossing as an indicator, the model predicts that the next solar cycle began in December 1976. Several authors[4,6,10] have predicted a low sunspot activity level during the next cycle (number 21) with a peak near 50–60. My analysis predicts a larger peak between 130 and 200 during 1981 or 1982. It will be interesting to watch the Sun during the next few years to find out for how long the spectral lines of the model are valid.

I thank Michael Gannis for preparing the figures, Kirby Spalding, Ilan Rothmuller and Esther Hill for their help in preparing this paper, and Paul Argo for providing a test case for analysis which aided in evaluating the effects of noise on unknown lines. This work was supported by US NELC and NAVAIR.

The advancing front of a spreading liquid

A WETTING liquid makes a zero contact angle to a solid, and a drop will spread completely over the surface. There are two stages in the spreading process[1,2]. Initially, the advancing front is pushed from behind by the hydrostatic head of the liquid. As the drop thins out this becomes unimportant and the front is pulled along by the unbalanced surface forces near the perimeter. The shape of the advancing front is not easy to observe without special lighting. In addition, for most liquids it cannot be seen unless precautions are taken to minimise evaporation. I report here microscopic observations which show that the advancing front has a remarkable structure. The moving front does not retain the shape of the original drop. Instead, depending on the liquid, it either assumes a scalloped periodic structure or else moves by a series of random advances, resembling the locomotion of an amoeba, but still with some approximate periodicity.

Figure 1 shows the advancing front for absolute ethyl alcohol spreading on the surface of aluminium that had been evaporated on a glass substrate. (Lighting and precautions for minimising evaporation are described in the legend.) A thin layer of liquid, 1,000–2,000 Å thick, moved ahead of the drop by as much as 1 mm. The drop followed, making a contact angle of about 0.1° to the precursor layer, as determined from the spacing of interference fringes. The front of the thin layer maintained a periodic, almost sinusoidal form as it advanced. This mechanism of spreading seems to be quite general. Similar results were found for a variety of liquids spreading on aluminium–isopropyl alcohol, *n*-heptane, toluene, *n*-octane (all reagent grade) and dimethyl silicone oil (molecular weight 340).

These liquids are all volatile and vapour transport may be an important part of the mechanism by which they spread. Observations were also made of the spreading of a non-volatile liquid, a high molecular weight hydrocarbon-substituted silicone oil, General Electric SF-1147 (mean molecular weight 2,000). It is so non-volatile at room temperature that effects of vapour transport are almost certainly absent. Measurement of the rate of evaporation in vacuum showed that less than one monolayer of molecules evaporates per day at room temperature. In air the evaporation would be even slower. The oil spreads on the surface of evaporated gold. The shape of the advancing front is shown in Fig. 2. Here the spreading was considerably slower than for alcohol due to the difference in viscosities (0.5 P for the oil and 0.014 P for ethyl alcohol). As the liquid spread, convex bulges develop at seemingly random points along the perimeter of the original round drop. These then move ahead and smaller protuberances develop. Though there was considerable randomness, it seems that there is an approximate periodicity here, as before with the alcohol. Again the front advanced far ahead of the bulk of the drop and, after several hours, covered all, or nearly all, of the solid surface.

These observations show that the spreading of a liquid on a solid is a complicated process. Typically, a thin layer moves out away from the rest of the drop, pulled by the unbalanced surface forces near the perimeter. This feature has been noted before[3] from observations of the drop profiles of spreading polymers. The periodic structure indicates an instability. This may be related to the Rayleigh–Taylor instability[4,5] that arises when two immiscible fluids are stratified with the denser fluid above. The Marangoni effect[6] also gives rise to instabilities but it depends on substantial variations of temperature or composition within the fluid, neither of which seems to be present here.

The following simplified picture may contain some of the correct physics. Consider the unbalanced surface force $\Delta\gamma$ at the liquid front

$$\Delta\gamma = \gamma_{\mathrm{SV}} - \gamma_{\mathrm{SL}} - \gamma_{\mathrm{LV}} \qquad (1)$$

The components are the familiar interfacial free energies for the solid–vapour, solid–liquid, and liquid–vapour interfaces. The force acts on the liquid near the interface and pulls it out over the unwetted surface of the solid. Its magnitude is proportional to the length of the liquid–solid–vapour line. In a part of the film of thickness, z, assume that, due to some local inhomogeneity of the solid surface, the front develops a semicircular convex bulge of radius R. The total force pulling outward on the semicircle is $\pi R\Delta\gamma$, whereas before the bulge developed, the force on the same liquid was only $2R\Delta\gamma$. The accelerating force is growing more rapidly than the resisting viscous force and there is a tendency for the front to become as convoluted as possible to take advantage of this. The counter-force is the excess pressure, $\Delta p = \gamma_{\mathrm{LV}}/R$, exerted by a convex curved surface. The pressure, Δp, is exerted over an area πRz and acts to oppose the tendency toward greater convolution. The two opposing tendencies balance when

$$\pi R\Delta\gamma = \pi Rz\gamma_{\mathrm{LV}}/R \qquad (2)$$

This then determines the stable radius of curvature for the undulations in the advancing front

$$R = z\gamma_{\mathrm{LV}}/\Delta\gamma \qquad (3)$$

If this is correct then it may be possible to make a direct measurement of $\Delta\gamma$ since all the other quantities in the equation can be measured.

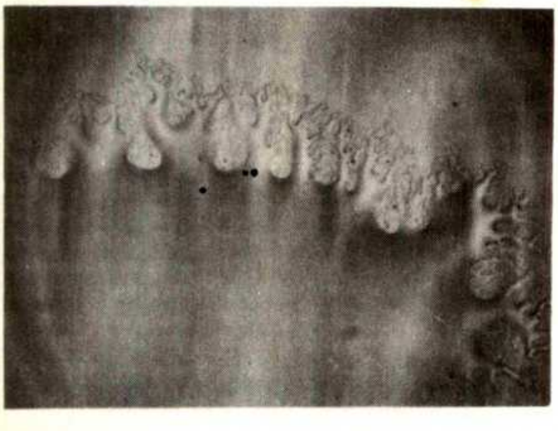

Fig. 1 Advancing front for a drop of ethyl alcohol spreading on the surface of evaporated aluminium. To minimise evaporation the experiment was performed in a cylindrical glass container covered by a glass plate. The bottom of the container was filled with alcohol and the substrate mounted about 1 cm above the surface of the liquid. To apply the spreading drop, the cover was moved aside just far enough to insert a long dropper that reaches nearly to the substrate surface. A drop of about 10^{-3} cm^3 of liquid was dispensed on to the surface and the cover replaced. The drop then spread and the thin advancing front remained stable for many minutes. Vertical illumination with nearly monochromatic light at 5,830 Å was reflected from the metal of the substrate to give interference fringes indicating the thickness of the oil. Successive fringes correspond to a thickness difference of 2,100 Å. The three pictures are for different times after the application of the drop. *a*, 30 s; *b*, 60 s; *c*, 200 s. At *c* the thickness of the advancing front is about 1,000 Å.

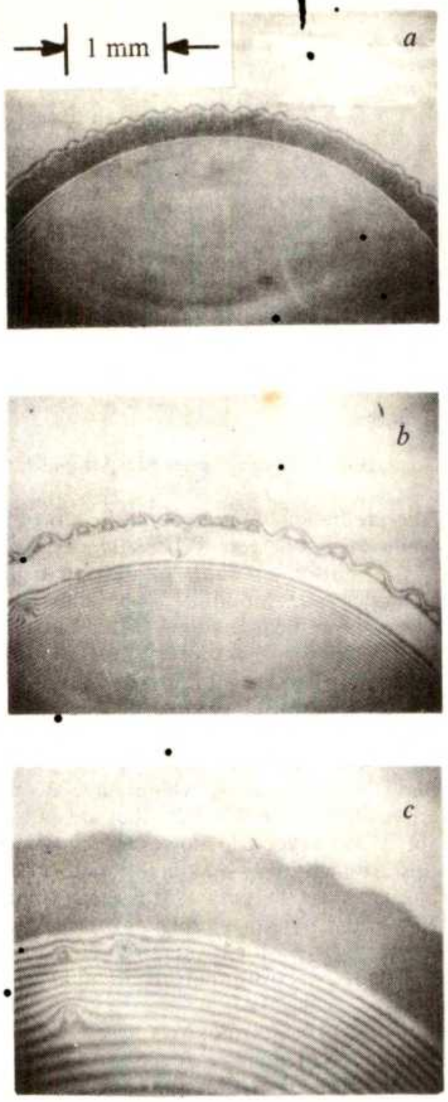

Fig. 2 Advancing front of silicone oil 5 min after application.

I thank B. Halon and D. M. Hoffman for preparing the substrates used in this work.

Silane triols of high stability in aqueous solution

ORGANO-SILICON compounds containing silanol groups are highly reactive, undergoing acid- or base-catalysed condensation to form siloxanes even in the presence of surface acid or base, the condensation being more facile in the order

$$\equiv\mathrm{SiOH} < =\mathrm{Si(OH)_2} < -\mathrm{Si(OH)_3}$$

By the use of plastic, quartz or washed borosilicate glass apparatus, several alkyl and aryl silanols and silane diols have been isolated[1–3]. But only aromatic silane triols (R $Si(OH)_3$) have been isolated[3], the corresponding alkyl derivatives being known only as transient species in solution. We report here that certain organo-silane triols display outstanding stability in aqueous solution.

The rate of condensation and polymerisation of silicic acid and organo-silanol derivatives in aqueous solution can be reduced by the addition of polar molecules such as ethers, alcohols and amines and of polymers containing similar groups[4]. The retardation is believed to be due to association through hydrogen bonding between silanol groups and the polar additive. Thus, polyethylene glycols retard the condensation of silicic acid, although inevitably, polymerisation proceeds to the point of gelation or the separation of colloidal silica.

We have prepared silane triols (I–IV), $R.Si(OH)_3$, in which R is an ether-containing moiety, by hydride insertion of the appropriate halo or alkoxy-silane into the allyl ethers of methoxy ethanol, methyl ethylene glycol, methyl trigol and so on, followed by hydrolysis

$CH_3O(CH_2CH_2O)\ CH_2CH_2CH_2Si(OH)_3$ (I)
$CH_3O(CH_2CH_2O)_2\ CH_2CH_2CH_2Si(OH)_3$ (II)
$CH_3O(CH_2CH_2O)_3\ CH_2CH_2CH_2Si(OH)_3$ (III)
$CH_3O(CH_2CH_2O)_{6-7}\ CH_2CH_2CH_2Si(OH)_3$ (IV)

The behaviour of the parent trichloro silyl derivatives of (I–IV) on contact with water revealed notable differences from simple alkyl halosilanes such as CH_3SiCl_3. The latter in water undergoes rapid hydrolysis with evolution of HCl, generation of heat and the rapid precipitation of a gel—essentially methylated silica gel This process is little affected by the presence in the water of, for example, $CH_3O(CH_2CH_2O)_3CH_2CH_2OH$. By contrast, the ether-containing compounds dissolve to give clear solutions for which, in spite of the low pH and raised temperature, low levels of polymerisation are indicated by cryoscopy, cloud point and ^{29}Si nuclear magnetic resonance (NMR).

Fig. 1 Number average molecular weights (cryoscopy) of compound (III).

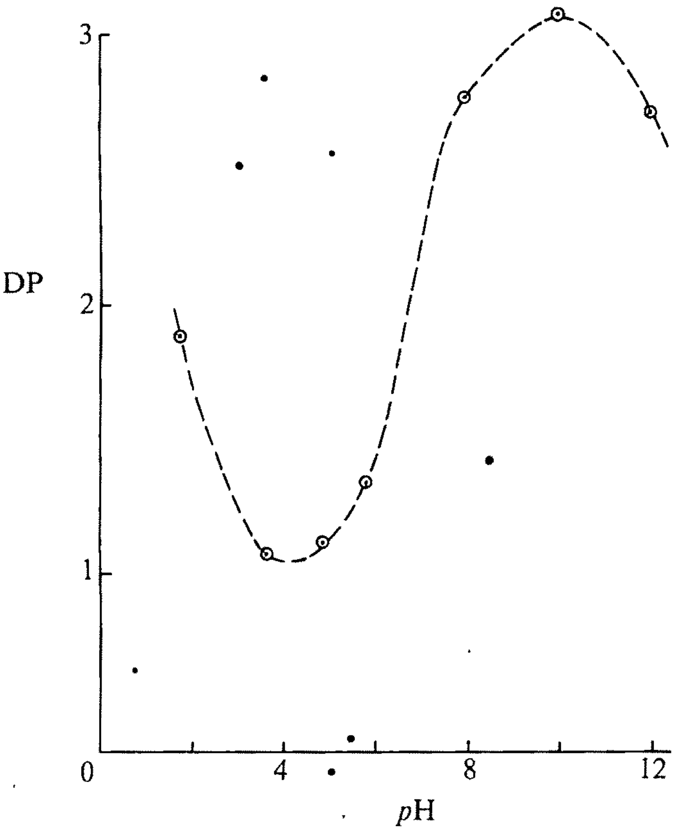

Table 1 Influence of number of ethylene oxide units on stability

Silane triol		Equilibrium DP in 5% (w/w) solution		
		pH 1	pH 5	pH 8
$CH_3O(CH_2CH_2O)CH_2CH_2CH_2Si(OH)_3$	(I)	7.2	2.4	7.1
$CH_3O(CH_2CH_2O)_2CH_2CH_2CH_2Si(OH)_3$	(II)	—	1.9	—
$CH_3O(CH_2CH_2O)_3CH_2CH_2CH_2Si(OH)_3$	(III)	1.9	1.1	3.4
$CH_3O(CH_2CH_2O)_{6-7}CH_2CH_2CH_2Si(OH)_3$	(IV)	2.9	1.1	1.6

DP, degree of polymerisation.

Figure 1 shows the number average molecular weights (cryoscopy) of (III) in 5% (w/w) aqueous solutions as a function of pH within the range 2–12 (after several days equilibration) when the highest degree of polymerisation found was only about 3.

The equilibrium molecular weights for (I–IV) (5% in water) at various pH values (Table 1) clearly illustrate that (I) and (II) are more susceptible to polymerisation than (III) and (IV), which contain the more ether groups.

The cloud point of a 5% solution of (III) did not change from the original value following 4.5 h of heating at 92 °C, whereas that of a 5% solution of (I) or (II) showed a reduction, indicating an increase of molecular weight.

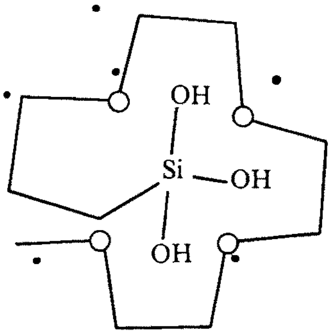

Fig. 2 Possible configuration to give stability.

The essentially monomeric nature of (III) in water was confirmed by ^{29}Si NMR. At pH 5–6 a 5% (w/w) solution contained only a trace of dimer while a 50% (w/w) solution still contained 75% monomer and only 25% dimer with no oligomers. An aqueous solution of $CH_3O(CH_2CH_2O)_3CH_2CH_2CH_2Si(OH)_3$ (III) evaporated to dryness gave a clear, viscous, water-soluble oil with a degree of polymerisation (cryoscopy) of about 7. ^{29}Si NMR showed this oil to contain no monomer or dimer and to undergo slow depolymerisation in water over several weeks.

The results suggest that by incorporating an ethylene oxide function by means of an Si–C bond into a silane triol, high solution stability can be attained. At pH 5, for example, at which the polymerisation of a silane triol is minimal and hydrogen bond formation near-optimal, the equilibrium degree of polymerisation reaches unity when four ether-oxygen atoms are involved. This stability could arise from the fact that the oligomers are soluble and hence, equilibrium would be in favour of depolymerisation. Compounds (I–IV), however, are all adequately soluble for this to apply and yet degree of polymerisation becomes unity only with (III).

This suggests that stability arises from full shielding of the silanol groups by intramolecular hydrogen bonding with the ether-oxygen atoms A possible configuration (ignoring interposed water molecules) is shown schematically in Fig. 2. A stable, associated pair can also be envisaged in which the silane triol head group of each molecule is embedded in the ethylene oxide chain of the other.

Palaeomagnetic field intensity variation recorded in a Brunhes epoch deep-sea sediment core

DEEP-SEA sediments have been shown to possess a natural remanent magnetisation (NRM) that often can be attributed to the statistical alignment of detrital magnetic grains in the Earth's magnetic field at or shortly after the time of their deposition[1,2]. In favourable circumstances this remanence can be interpreted as a record of palaeomagnetic field behaviour[3,4] In the study reported here we have attempted to describe relative variations in palaeomagnetic field intensity on a time scale of 10^4–10^5 yr, during the past 700,000 yr, using the palaeomagnetic record of deep-sea sediment piston core RC10-167 (33°2′N, 150°23′E), which has an exceptionally thick section of sediment deposited during the Brunhes normal polarity epoch[5] (Fig. 1). After subtracting the stratigraphic contribution of several distinct volcanic ash layers interspersed with the otherwise uniform pelagic sediment[6], we calculate an average deposition rate of 2.1 cm kyr^{-1} between the adjusted level (1,470 cm) of the Brunhes–Matuyama boundary (t=700,000 yr) and the top of the core, assumed t=0 yr. A 2-cm thick sample, representing about 1,000 yr of deposition, was taken at an average interval of 3.3 cm (representing about 1,600 yr). This sampling placed a theoretical limit of 3,000–4,000 yr on the period of a resolvable sinusoidal variation.

Progressive alternating field (AF) demagnetisation of the NRM in 12 pilot samples showed consistent directions of magnetisation, to within 10° of the initial value, with demagnetisation up to 400 Oe. The mean remanent inclination after 150-Oe AF is 51.2°, close to the expected dipole inclination (52.4°) for the core site latitude. The median demagnetising field (MDF; peak AF required to remove half the initial remanence) is high and relatively uniform, averaging 270±40 Oe (s.d.). The total magnetic coercivity distribution was investigated by progressive AF demagnetisation of an anhysteretic remanent magnetisation (ARM; imparted in a 1.0-Oe direct field coaxial with a 1,000-Oe AF) and an isothermal remanent magnetisation (IRM; imparted in a 1,000-Oe direct field). The average MDF values for the 12 specimens are 230±15 Oe for ARM and 170±25 Oe for IRM.

On the basis of these experiments we conclude that: (1) the NRM has a high magnetic stability with little contribution from unstable magnetic components; (2) the small scatter in MDF values for NRM, ARM and IRM shows that the magnetic coercivity spectrum is quite uniform over the length of the core; (3) the high stabilities of remanence and the relative stabilities of ARM and IRM[7] are indicative of fine-grained magnetic carriers; (4) the coercivity spectrum of NRM is more closely approximated by ARM than by IRM in this sediment.

We assume that the magnetisation acquisition process was the same at each stratigraphic level in the sediment and that the intensity of NRM is only a function of palaeofield strength and the magnetic mineral concentration. The variation with stratigraphic level in the sediment (hence age) of NRM intensity, normalised to take into account fluctuations in magnetic mineral concentration, then might provide a record of relative variations in palaeomagnetic field intensity. We do not deal explicitly with the still poorly understood details of the magnetisation acquisition process in the sediment, and so absolute values of palaeofield strength are not obtained directly by this method. A similar approach has been used to describe palaeofield intensity variations across magnetic polarity transitions in deep-sea sediment cores[8,9].

Because of our conclusion (4) above, we have chosen to use the intensity of ARM as a relative measure of the quantity of magnetic mineral carrying the NRM. The variation with depth in this core of ARM, however, is similar to that of initial susceptibility (Fig 1). Together they provide an internally consistent record of fluctuating magnetic mineral concentration. This correspondence supports our inference of a coercivity spectrum that is uniform over the core length since the magnitude of ARM and initial susceptibility each are affected preferentially by different magnetic grain size ranges. By assuming that over this sediment core the intensity of NRM is uniformly and directly proportional to the strength of the magnetising field[1,10] and to magnetic mineral content as measured by ARM[11], the ratio of NRM/ARM should be directly proportional to palaeofield strength alone. In practice, we have used the ratio after partial demagnetisation of each remanence in 150-Oe AF, to remove any possible unstable magnetic components.

A plot of the ratio of NRM/ARM (partially demagnetised) in the Brunhes section of core RC10-167 is shown in Fig. 2. The data have been interpolated linearly to 512 equally-spaced values (from the 448 samples measured), giving an interpolated interval of 2.9 cm (or about 1,400 yr). This was done to facilitate further analysis of the data. The ratio of NRM/ARM has a variation of as much as 100%, but more typically about 50%, about a mean value of 0.10 in the core. The record is nearly stationary as the linear trend is only −0.0036 for 1,470 cm (or 700,000 yr). Visually, three wavelength components seem to dominate the record. a broad baseline fluctuation with an apparent wavelength of about half the record length, a variation with an apparent wavelength of about 1 m which gives the record its dominant character, and last, a short wavelength component that seems to ride on the longer wavelength variations.

A power spectrum analysis was performed on this record to identify better any periodic components. Power spectra were estimated using a direct (fast Fourier transform) method with a cosine-rectangular window, and finally smoothed with a three-point Hanning filter[12] (Fig. 2). We observe an initial falloff in power to a wavelength of approximately 25 cm beyond which the spectrum is flatter and approximates the spectrum of white noise. This change in overall slope in the power spectrum may be a function of the remanence acquisition mechanism in these sediments, the periodic content of geomagnetic intensity variations or a combination of these. For example, deep-sea sediments may not acquire a stable remanence at the instant of deposition but rather at, or more importantly, over some depth below the sediment–water interface[1,2]. The record of palaeomagnetic field variations with periodicity of the order of the time in which stable remanent magnetisation is acquired will tend to be obscured. On the other hand,

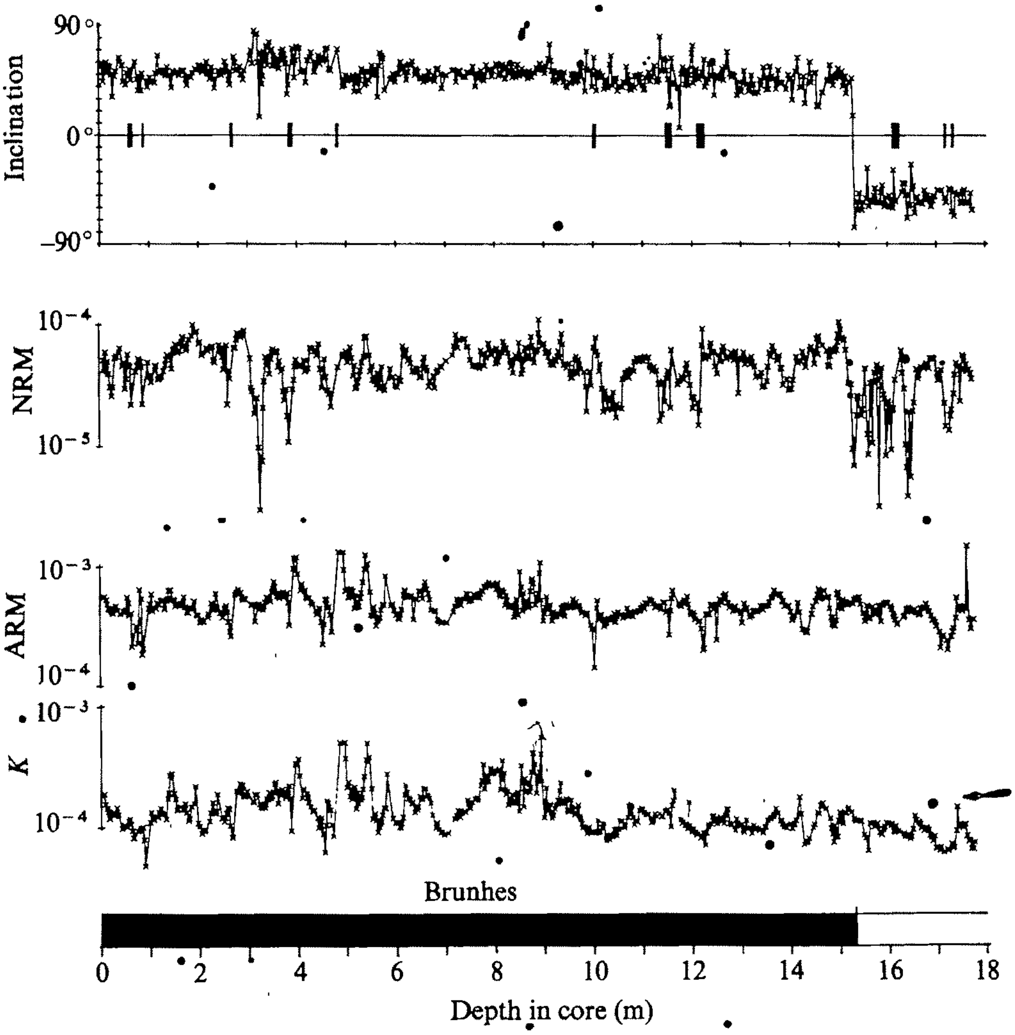

Fig. 1 Inclination direction and intensity of natural remanent magnetism (NRM) against depth in deep-sea sediment core RC10-167. Change in sign of inclination at 15.3-m depth is interpreted as the Brunhes–Matuyama magnetic reversal boundary[5]. Solid bars on axis of inclination plot are the positions of volcanic ash layers[6]. Also shown is the intensity of ARM and the bulk susceptibility (k). The direction and intensity of NRM and the intensity of ARM are after AF demagnetisation in 150 Oe. Magnetisation units are in c.g.s. g^{-1}.

sediment cores with higher deposition rates will need to be studied to determine the contribution of geomagnetic field intensity variations to the shorter wavelength (less than about 12,000 yr) portion of the spectrum

The power spectrum is dominated by periodic components with wavelengths of several metres and greater, and a component that forms a more coherent peak centred at a wavelength of about 90 cm. We hesitate to ascribe the longer wavelength variation in NRM/ARM to that of palaeomagnetic field intensity. Our record is too short to evaluate such an apparent long period variation and it may reflect some long term lithological or diagenetic control on the remanent magnetism of the sediment that was not effectively normalised by the procedures used. On the other hand, because of its better defined and persistant character in the record, we feel more confident in interpreting the 90-cm wavelength variation in NRM/ARM as a previously undescribed component of secular variation of palaeointensity. Its apparent period is about 43,000 yr.

A bandpass filter centred on this wavelength (Fig. 3) shows that this component has about a 30% variation about its mean value, an amplitude of magnitude similar to that obtained for palaeointensity variation[13]. We note, however, that our interpreted palaeointensity variation has a period about four times greater than previous estimates[14]. This apparent discrepancy may be due to an inadequate definition of variations in the relatively short archaeomagnetic record on which previous estimates of palaeointensity periodicity have been made. On the other hand, it may simply reflect a more complicated variation in palaeointensity than previously suspected. The cause of this discrepancy is difficult to resolve, particularly because our record seems to lack sufficient resolution to detect the shorter periodicity of palaeointensity variation (about 10,000 yr) estimated from the archaeomagnetic record.

The long period and relatively large amplitude of the inferred 43,000-yr palaeointensity variation suggest that it is due primarily to a secular variation in the strength of the main dipole field, and consequently must reflect processes within the Earth's core associated with its generation. Malkus[15] has proposed that the geomagnetic dynamo may be driven by forces arising from the precession of the Earth's rotational axis. The efficacy of this energy source in driving the geomagnetic dynamo has been questioned by some[16,17] while others[15,18] maintain that it is the basic driving mechanism (although convection may play some part). The Earth's rotational axis precesses about the normal to ecliptic with a period of about 21,000 yr. The angle between the rotational axis and the normal to the ecliptic (the obliquity), however, does not stay constant but varies between approximately 22.1° and 24.5°, with an average period city of about 41,000 yr (ref. 19). The precessional force on the core can be expected to vary with the obliquity. If precession has a role in driving the geomagnetic dynamo, some sympathetic variation with obliquity might be expected in the Earth's magnetic field. We suggest that the apparent 54,000-yr variation in palaeointensity recorded in RC10-167 is near to the periodicity of obliquity, and reflects the modulation of a precessionally-driven dynamo by changes in the obliquity.

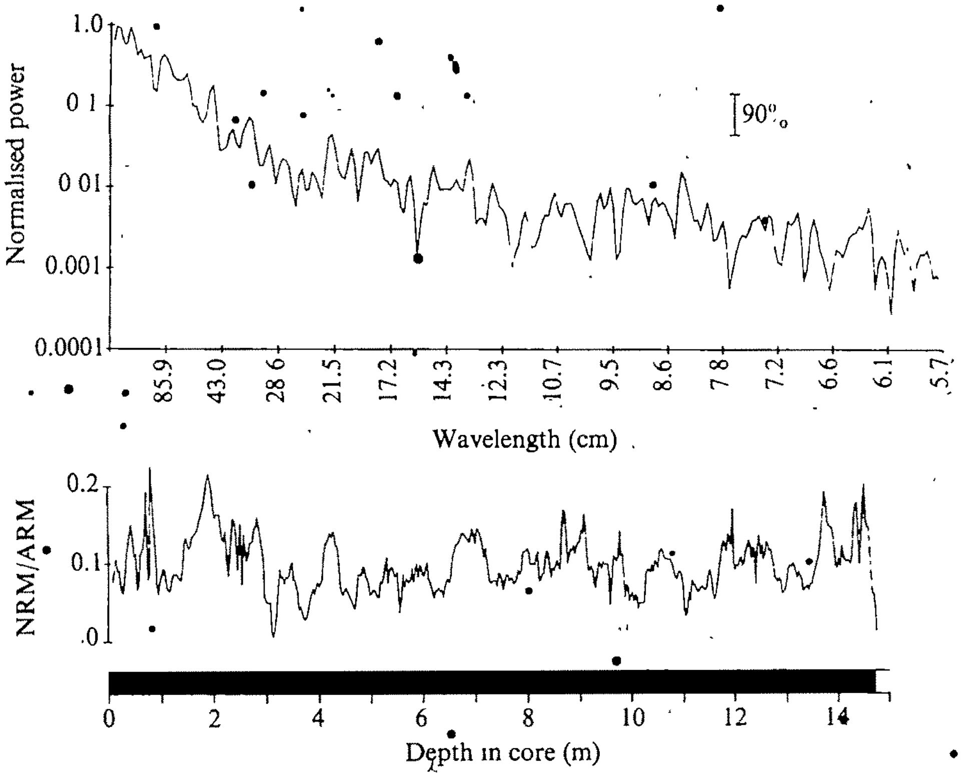

Fig. 2 Lower trace shows the ratio NRM/ARM, against ash-free depth in core RC10-167. The initial set of 448 sample measurements has been interpolated linearly to produce 512 equally-spaced values. Upper trace shows power spectrum of NRM/ARM variation record shown in lower trace, using the fast Fourier transform with a cosine-rectangular window. Estimates of power spectra were smoothed further by a three-point weighted (Hanning) filter. The solid bar is an estimate for the 90% confidence interval

Although the magnitude of precessional force may vary by only less than 10% between times of maximum and minimum obliquity[20], much less than the variation in palaeointensity observed here, the relationship between the magnitude of precessional force and the field generated may not be simple. It is possible that some critical amount of energy is required to sustain dynamo action, as found in laboratory dynamo models[21]. Near this critical value, relatively small variations in contributing forces, such as precession, may have pronounced effects in the magnitude of the generated magnetic field. Figure 3 shows the variation with time in the Earth's obliquity[19] and in inferred geomagnetic palaeointensity as recorded in core RC10-167, assuming a linear time scale between the top of the core and the level of the Brunhes–Matuyama boundary. There seems to be a good correspondence in the expected sense between the palaeointensity and obliquity variations over this time, with obliquity maxima apparently preceeding the inferred intensity maxima by about 5,000 yr.

There is no statistical compulsion to accept at the 90%

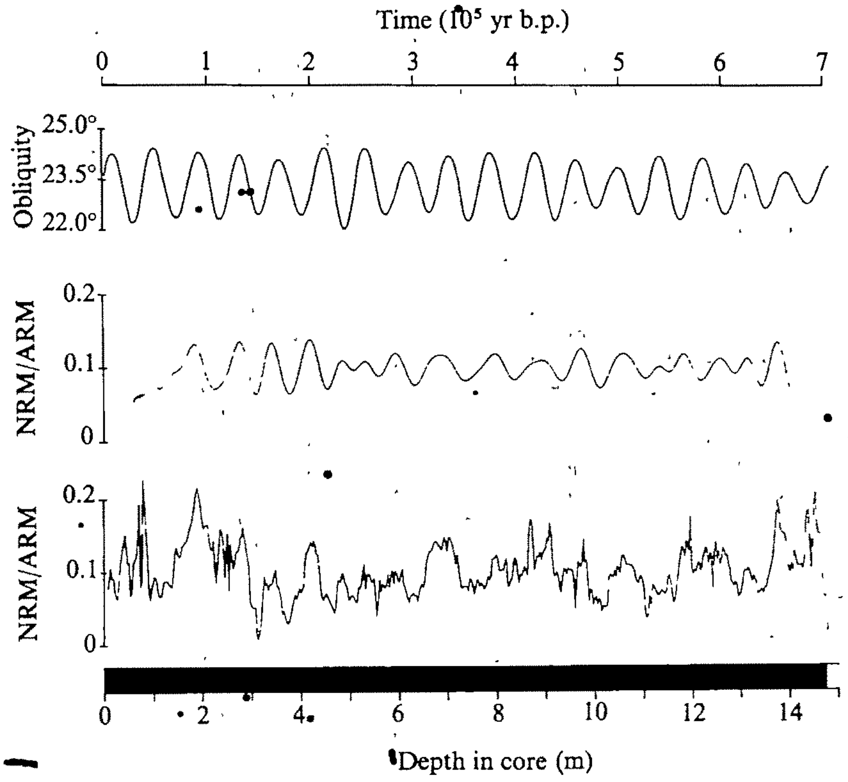

Fig. 3 The variation of NRM/ARM in core RC10-167 (bottom) and the same record (middle) filtered with a cosine-tapered band-pass centred at a wavelength of 90 cm The time scale is based on the assumption of a uniform deposition rate (volcanic ash layers excluded) between the top of the core ($t = 0$ yr) and the level of the Brunhes–Matuyama magnetic reversal boundary ($t = 700{,}000$ yr). Also shown (top) is the variation with time in the Earth's obliquity from ref. 19.

confidence level the existence of the 43,000-yr period in the NRM/ARM record on the basis of its power spectral density alone. We have some confidence in its reality, however, on the strength of two arguments—the apparent phase coherence with the variation in the Earth's obliquity and the knowledge that such a correlation is not physically absurd We recognise, however, that results from a single sediment core should be viewed with caution, especially when a global phenomenon is invoked in explanation. It is possible that the inferred palaeointensity variation in this core reflects a more local palaeomagnetic field behaviour or a physical property of the sediment, in spite of the magnitude and internal consistency of the observed NRM/ARM variation. Other periodicities of palaeofield intensity may also be involved These may be difficult to identify with certainty in this core because of the limited record length available to characterise any longer period variations, and because of the restriction imposed by the sampling interval and sediment deposition rate in resolving with confidence any shorter period variations. Nevertheless, we feel that the data described here provide sufficient basis for serious consideration of a 43,000-yr variation in the palaeomagnetic field intensity during the past 700,000 yr. Confirmation of the existence of such a variation is being sought in a deep-sea sediment core of different lithology and geographically remote from RC10-167. We point out, however, that of approximately 1,000 cores that we have studied palaeomagnetically from the L-DGO core collection, RC10-167, is unique in having the longest complete record of the Brunhes normal magnetic epoch

If the apparent correlation between variation in geomagnetic palaeointensity and the Earth's obliquity is substantiated by further work, several implications are apparent. First, it would provide evidence that forces arising from the Earth's precession contribute to driving the geomagnetic dynamo Second, there is now good evidence that long term climatic variations have been controlled, at least in part, by the Earth's orbital parameters[22] Therefore, a correspondence between some component of climatic change and variations in the Earth's magnetic field can be expected, due to a possible common mechanism

K. McCamy provided helpful comments, W. Lowrie and W L Donn read the manuscript and D. Lafferty made the measurements. This research was supported by the NSF.

Growth of *Pinus pumila* and climate fluctuation in Japan

Tree-ring analysis shows a relationship between annual ring growth and climatic changes in the United States[1–3] and in the Scandinavian countries[4] We have measured annual growth in terms of elongation of the terminal shoot of dwarf pine, *Pinus pumila* (Pallas) Regel, which is common in the alpine zone of Japan and eastern Siberia. This tree was used as the indications of annual growth are clearer than in other plants The ages of branches used for measurement are 50–200 yr, although dating at >100 yr is difficult We discuss here the relationship between the fluctuation in annual elongation of dwarf pine and climatic changes in Japan or in higher latitude of Northern Hemisphere

Elongation of the terminal bud of *Pinus pumila* starts in early June and terminates in late July The buds do not elongate further in the following years. Thus annual elongations of the past years are measurable and the number of years so indicated agrees with the number of annual rings at the node. Annual elongation of the main shoot of the pine was measured on trees in many locations of the alpine zone of Japan There was uniformity of annual variations in elongation among most of populations of different locations (Figs 1 and 2) Such a uniformity was even observed between the populations of Mt Hakusan and Mt

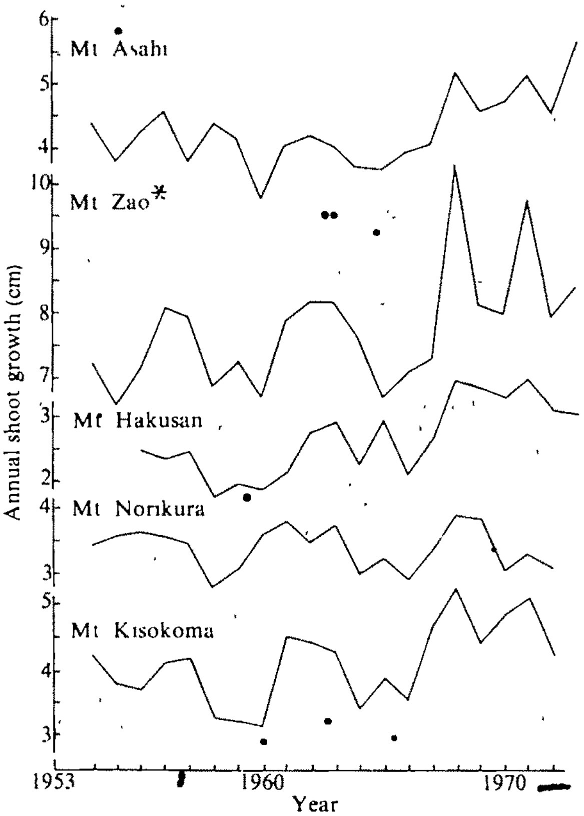

Fig. 1 Annual shoot growth of *Pinus pumila* in five stands of the alpine zone of Japan. Values for shoot growth are means of 60–20 plants The stands are shown in Fig. 2. Correlation coefficient between each two stands. Mt Kisokoma–Mt Norikura, $r = 0.396$; Mt Kisokoma–Mt Hakusan, $r = 0.873$; Mt Kisokoma–Mt Zao, $r = 0.785$; Mt Kisokoma–Mt Asahi, $r = 0.701$; Mt Norikura–Mt Hakusan, $r = 0.362$; Mt Norikura–Mt Zao, $r = 0.325$; Mt Norikura–Mt Asahi, $r = 0.072$; Mt Hakusan–Mt Zao, $r = 0.733$; Mt Hakusan–Mt Asahi, $r = 0.674$; Mt Zao–Mt Asahi, $r = 0.768$. *Hybrid population of *P. pumila* and *P. parviflora*.

Asahi, though these two mountains are about 950 km apart. This result suggests that the growth of the pine is affected by climatic factors that predominate over a wide region of Japan.

Annual elongation of the pine of Mt Kisokoma correlated positively with the total sunshine in June, July and August of the previous year, and/or with the mean temperature of June, July and August of the previous year (Fig. 3). There is presumably some dependence of growth on rain or snowfall Correlation between growth and sunshine, however, is apparent even if effects of rainfall are ignored.

There are many reports on climatic changes of the Earth[5–7]. We measured the annual elongation of the old pine (about 200 yr old) at Mt Norikura going back to 1890, and its fluctuation was compared with the data on fluctuation of temperature around the world shown by G. S. Callendar (Fig. 4). In Fig. 4, the temperature of sub-arctic zones around 1890–1900 is shown as low and that around 1940–1950 as high; elongation of the shoot was small around 1900–1910, and large around 1940–1950. Thus fluctuation in elongation varies with temperature in the sub-arctic (60–73 °N) with a slight time lag. This coincidence with temperature fluctuation in the sub-arctic zone rather than in Japan is of note. A similar relationship was seen in other population of *Pinus pumila* with other data of temperature fluctuation in the Northern Hemisphere (data of J. M. Mitchell). Thus the growth of the pine in the alpine zone of Japan accurately reflects the fluctuation of temperature in the Northern Hemisphere, especially in the sub-arctic zone.

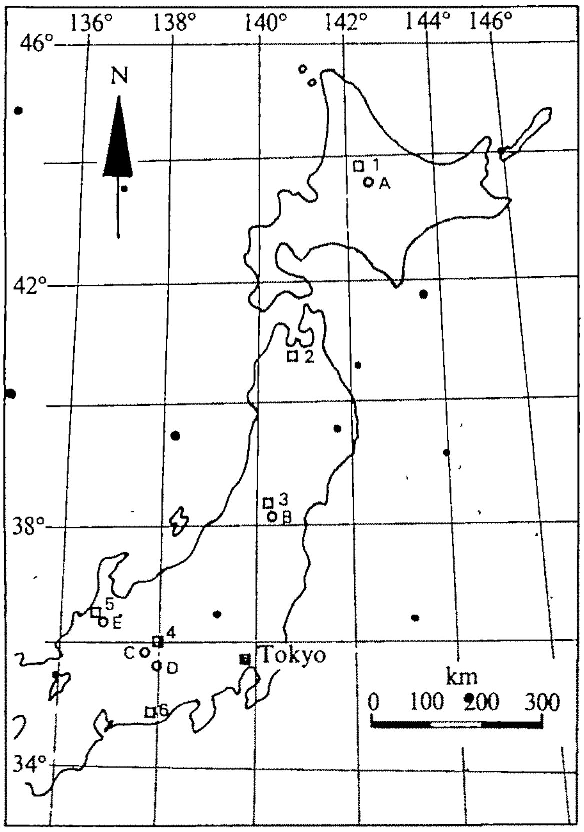

Fig. 2 The location of the sample stands of *P. pumila* and the meteorological stations where climatic data was collected. A, Mt Asahi; B, Mt Zao; C, Mt Norikura; D, Mt Kisokoma; E, Mt Hakusan; 1, Asahikawa; 2, Aomori; 3, Yamagata; 4, Matsumoto; 5, Kanazawa and 6, Hamamatsu.

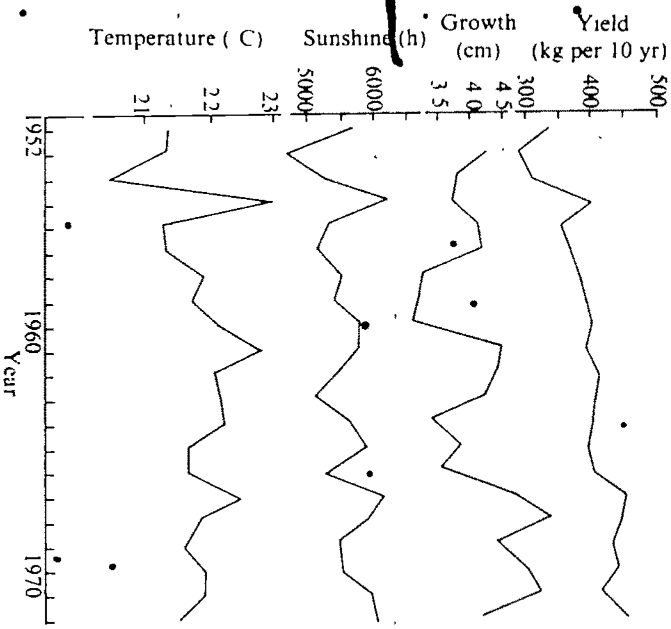

Fig. 3 Fluctuation of annual shoot growth of *Pinus pumila* of Mt Kisokoma in Japan and fluctuation of temperature (mean of June, July and August at six stations) and sunshine (sum of June, July and August at six stations) and mean rice yield per acre in Japan[8,9]. Each value of shoot growth is the mean of 40 plants. The six meteorological stations are shown in Fig. 2. Correlation and regression coefficients: (1) Temperature of previous year (x)–shoot growth (y), $r = 0.291$, $Y(\text{cm}) = 0.303x(°\text{C}) + 2.538$. (2) Sunshine of previous year (x)–shoot growth (y), $r = 0.407$, $Y(\text{cm}) = 0.001x(\text{h}) + 0.726$. (3) Rice yield previous year (x)–shoot growth (y), $r = 0.518$, $Y(\text{cm}) = 0.007x(\text{kg per 10 a}) + 1.306$. (4) Sunshine ($x$)–temperature ($y$), $r = 0.636$, $Y(°\text{C}) = 0.001x(\text{h}) + 17.080$. (5) Sunshine ($x$)–rice yield ($y$), $r = 0.685$, $Y(\text{kg per 10 a}) = 0.072x(\text{h}) - 7.714$. (6) Temperature ($x$)–rice yield ($y$), $r = 0.552$, $Y(\text{kg per 10 a}) = 43.207x(°\text{C}) - 549.355$.

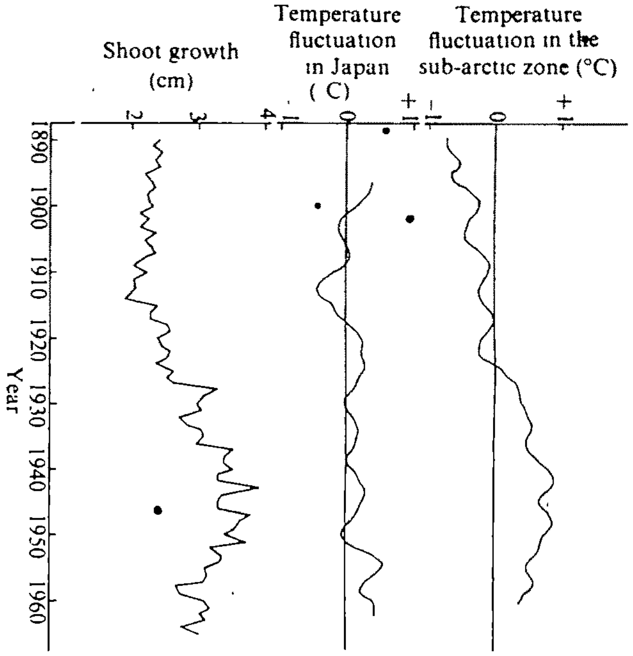

Fig. 4 Fluctuation of annual shoot growth of *Pinus pumila* of Mt Norikura in Japan and fluctuation of temperature in Japan and the sub-arctic (60–73°N) zone Values of shoot growth are the means of 33 plants. Climatic data from G. S Callendar[6]. Correlation coefficient and regression equations: (1) Temperature in the sub-arctic zone (x)–pine growth in Mt Norikura (y), $r = 0.835$, $Y(\text{cm}) = 0.895x(°\text{C}) + 2.616$. (2) Temperature in Japan (x)–pine growth in Mt Norikura (y), $r = 0.396$, $Y(\text{cm}) = 0.982x(°\text{C}) + 2.687$. (3) Temperature in the sub-arctic zone (x)–temperature in Japan (y), $r = 0.298$, $Y(°\text{C}) = 0.144x(°\text{C}) + 0.048$.

Chemistry

CATSIMPOOLAS, Nicholas (edited by) Isoelectric Focusing Pp xii+265 ISBN-0-12-163950-9 (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $23 50, £16 70

EICHHOLZ, Geoffrey G Environmental Aspects of Nuclear Power Pp xx+683 ISBN-0-250-40138-X (Ann Arbor, Michigan Ann Arbor Science Publishers, Inc, Chichester John Wiley and Sons, Ltd, 1976) £19 50 $30 25

GALUS, Z Fundamentals of Electrochemical Analysis Translation editor G F Reynolds (Ellis Horwood Series in Analytical Chemistry) Pp xviii+520 ISBN-85312-036-6 (Chichester Ellis Horwood, Ltd, Warsaw PWN—Polish Scientific Publishers, New York Halsted Press, a Division of John Wiley and Sons, Inc, 1976) £23 50, $44 65

GROSS, R W F, and BOTT, J F (edited by) Handbook of Chemical Lasers Pp x+744 ISBN-0-471-32804-9 (New York and London Wiley-Interscience, John Wiley and Sons, 1976) £31, $49

JONES, J Bryan, SIH, Charles J, and PERLMAN, D (edited by) Applications of Biochemical Systems in Organic Chemistry, Part 1 (Techniques of Chemistry, Vol 10) Pp xii+505 ISBN-0-471-93267-1 (New York and London Wiley-Interscience, John Wiley and Sons, 1976) £24 25, $39

JONES, J Bryan, SIH, Charles, I, and PERLMAN, D (edited by) Applications of Biochemical Systems in Organic Chemistry, Part 2 (Techniques of Chemistry, Vol 10) Pp xii+506-1065 ISBN-0-471-93270-1 (New York and London Wiley-Interscience, John Wiley and Sons, 1976) £26 65, $42.50

KATRITZKY, A R, and BOULTON, A J (edited by) Advances in Heterocyclic Chemistry, Vol 20 Pp ix+324 ISBN-0-12-020620-X (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976.) $33 50, £23 80

KERKER, Milton (edited by) Colloid and Interface Science Vol 2 Aerosols, Emulsions, and Surfactants Pp xx+481 ISBN-0-12-404502-2 (v 2) $21, £14 90 Vol 3 Adsorption, Catalysis, Solid Surfaces, Wetting, Surface Tension, and Water Pp xx+548 ISBN-0-12-404503-0 (v 3) $22 50, £15 95 Vol 4 Hydrosols and Rheology Pp xviii+587 ISBN-0-12-404504-9 (v 4) Vol 5 Biocolloids, Polymers, Monolayers, Membranes, and General Papers Pp xvi+507 ISBN-0-12-404595-7 (v 5) $22, £15 60 (Proceedings of the International Conference on Colloids and Surfaces—50th Colloid and Surface Science Symposium, held at San Juan, Puerto Rico, on June 21-25, 1976) (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich Publishers, 1976)

KIER, Lemont B, and HALL, Lowell H Molecular Connectivity in Chemistry and Drug Research (Medicinal Chemistry a Series of Monographs) Pp xiii+257, ISBN-0-12-406560-0 (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $27, L19 20

KOROLKOVOS, Andrejus, and BURCKHALTER, Joseph H Essentials of Medicinal Chemistry Pp vii+697 ISBN-0-471-12325-0 (New York and London Wiley-Interscience, John Wiley and Sons, 1976) £17 40, $29 95

LEHMAN, Thomas A, and BURSEY, Maurice M Ion Cyclotron Resonance Spectrometry Pp xi+230 ISBN-0-471-12530-X (New York and London Wiley-Interscience, John Wiley and Sons, 1976) £17, $27 30

LEWIS, Marc S, and WEISS, George H (edited by) Proceedings of the Conference, Fifty Years of the Ultracentrifuge, Bethesda, Maryland, February 24-26, 1975 Pp 286 ISBN-0-7204-0511-4 (Amsterdam, New York and Oxford North-Holland Publishing Company, 1976) Dfl 115, $45 95

LOEWENTHAL, R E, and MARAIS, G v R Carbonate Chemistry of Aquatic Systems Theory and Application Pp xi+433 ISBN-0-250-40141-X (Ann Arbor, Michigan Ann Arbor Science Publishers, Inc, Chichester John Wiley and Sons, Ltd, 1976) £16, $24 75

MOSKOVITS, Martin, and OZIN, Geoffrey A (edited by) Cryochemistry Pp xi+532 ISBN-0-471-61870-5 (New York and London Wiley-Interscience, John Wiley and Sons, 1976) £25 85, $39

PEARCE John, and GLYNN, Erica Stereochemistry An Introductory Programme with Models Pp 171+cut-out kit ISBN-0-471-67467-2 (London and New York John Wiley and Sons, 1976) £2 75, $5

PECSOK, Robert L, SHIELDS, L Donald, CAIRNS, Thomas and McWILLIAM, Ian G Modern Methods of Chemical Analysis Second edition Pp xviii+573 ISBN-0-471-67662-4 (New York and London John Wiley and Sons, 1976) $21 50, £13 50

PULLMAN, Bernard, and PARR, Robert (edited by) The New World of Quantum Chemistry (Proceedings of the Second International Congress of Quantum Chemistry held at New Orleans, U S A, April 19-24, 1976 International Academy of Quantum Molecular Science) Pp viii+356 ISBN-90-277-0762-6 (Dordrecht and Boston, Mass D Reidel Publishing Company, 1976) Dfl 75, $29

REMBAUM, Alan, and SEGÉGNY, Eric (edited by) Polyelectrolytes and Their Applications (Charged and Reactive Polymers, Vol 2) Pp viii+343 ISBN-90-277-0561-5 (Dordrecht and Boston, Mass D Reidel Publishing Company, 1975) Dfl 115, $39 50

SÉLÉGNY, Eric (edited by) Charged Gels and Membranes, Part 1 (Charged and Reactive Polymers, Vol 3) Pp xviii+305 ISBN-90-277-0665-4 (Dordrecht and Boston, Mass D Reidel Publishing Company, 1976) Dfl 105, $39

SENNING, A (edited by) Topics in Sulfur Chemistry, Vol 1 Pp vii+223 ISBN-3-135261-01-8 (Stuttgart Georg Thieme Publishers 1976) DM98

SHAFIZADEH Fred, ŠARKANEN, Kyosti V, and TILLMAN, David A (edited by) Thermal Uses of Properties of Carbohydrates and Lignins (Symposium, 172, National Meeting of the American Chemical Society, San Francisco, September, 1976) Pp xi+320 ISBN-0-12-637750-2 (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $15, £10 65

SHEN, Mitchel (edited by) Plasma Chemistry of Polymers Pp x+281 ISBN-0-8247-6511-7 (New York and Basel Marcel Dekker, Inc, 1976) SFrs 98)

SILVER, Brian L Irreducible Tensor Methods an Introduction for Chemists (Physical Chemistry, a Series of Monographs, Vol 36) Pp xvii+226 ISBN-0-12-643650-9 (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $26 50, £18 80

WICHTERLE, Ivan, LINEK, Jan, and HALA, Eduard Vapour-Liquid Equilibrium Data Bibliography, Supplement 1 Pp vii+333 ISBN-0-444-41161-5 (Amsterdam, Oxford and New York Elsevier Scientific Publishing Company, 1976) Dfl 100, $39 95

ZLATKIS, A, and KAISER, R E (edited by) HPTLC-High Performance Thin-Layer Chromatography (*Journal of Chromatography* Library, Vol 9) Pp 240 ISBN-0-444-41525-4 (Amsterdam, Oxford and New York Elsevier Scientific Publishing Company, Bad Durkheim Institute of Chromatography, 1977) Dfl 100, $43 95

Technology

ALCOCK, C B Principles of Pyrometallurgy Pp xiii+348 ISBN-0-12-049850-3 (London and New York Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) £8 80, $19 25

BASILE, Paul S (edited by) Energy Demand Studies Major Consuming Countries—Analyses of 1972 Demand and Projections of 1985 Demand (First Technical Report of the Workshop on Alternative Energy Strategies) Pp xiv+553. ISBN-0-262-23076-3 (Cambridge, Mass and London The MIT Press, 1976) $20

BASILE, Paul S (edited by) Energy Demand Studies Major Consuming Countries—Analyses of 1972 Demand and Projections of 1985 Demand (First Technical Report of the Workshop on Alternative Energy Strategies (WAES) Pp.xiv+551. ISBN-0-262-23076-3 (Cambridge, Mass and London The MIT Press, 1976) £15

CHEN, C H (edited by) Pattern Recognition and Artificial Intelligence. (Proceedings of the Joint Workshop held at Hyannis, Massachusetts, June 1-3, 1976.) Pp ix+621 ISBN-0-12-170950-7 (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $28.50, £20 25

CHIGIER, N A (edited by) Pollution Formation and Destruction in Flames (Progress in Energy and Combustion Science, Vol 1) Pp 219 ISBN-0-08-020307-8 (Oxford and New York Pergamon Press, 1976) £25, $50

FOUST, O J (edited by) Sodium-NaK Engineering Handbook Vol 2 Sodium Flow, Heat Transfer, Intermediate Heat Exchangers, and Steam Generators Pp xii−390 ISBN-0-677-03030-4 (New York, London and Paris Gordon and Breach, Science Publishers, 1976) £17

FRANKLIN, Raoul N Plasma Phenomena in Gas Discharges (Oxford Engineering Science Series) Pp ix+249 ISBN-0-19-856113-X (Oxford Clarendon Press, London Oxford University Press, 1976) £15 net (Pub 30 Dec '76)

FULLER, A J Baden Worked Examples in Engineering Field Theory (Pergamon International Library of Science, Technology, Engineering and Social Studies: Applied Electricity and Electronics Division) Pp x+321. ISBN-0-08-018142-2. (Oxford and New York Pergamon Press, 1976) Hardback £10 $20, Flexi £5 $10.

GREVE, Tim, Lied, Finn, and TANDBERG, Eril (edited by) The Impact of Space Science on Mankind (Nobel Foundation Symposium) Pp ix+125 ISBN-0-306-33701-0 (New York and London Plenum Press, 1976) $23 40

LOMNITZ, C, and ROSENBLUETH, E (edited by) Seismic Risk and Engineering Decisions (Developments in Geotechnical Engineering, 15) Pp.ix+425 ISBN-0-444-41495-0 (Amsterdam, Oxford and New York Elsevier Scientific Publishing Company, 1976) Dfl 115, $45 95

MONTGOMERY, Douglas C Design and Analysis of Experiments Pp xiv+418. ISBN-0-471-61421-1. (New York and London John Wiley and Sons, 1976) £13 50, $21 50

MURTHY, S N B (edited by) In association with OSBORN, J R, BARROWS, A W, and WARD, J R Aerodynamics of Base Combustion (Progress in Astronautics and Aeronautics, Vol 40 (Technical papers from the Workshop on Aerodynamics of Base Combustion, May 1974, subsequently revised for this volume) Pp xiv−521 ISBN-0-915928-04-3 (New York American Institute of Aeronautics and Astronautics, Cambridge, Mass and London The MIT Press, 1976) $35

ORTEGA, James M (edited by) Computer Science and Scientific Computing (Proceedings of the Third ICASE Conference on Scientific Computing, Williamsburg, Virginia, April 1 and 2, 1976) Pp x+306 ISBN-0-12-528540-X (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $15 50, £9 45

ROSEN, Alan (edited by) Spacecraft Charging by Magnetospheric Plasmas (Progress in Astronautics and Aeronautics, Vol 47 Technical papers selected from the AIAA/AGU Symposium, June 1975, subsequently revised for this volume) Pp xii+291 ISBN-0-915928-11-6 (New York American Institute of Aeronautics and Astronautics, Cambridge, Mass and London The MIT Press, 1976) $28

ROTBLAT, J (edited by) Nuclear Reactors To Breed or not to Breed (A Pugwash Debate on Fast Breeder Reactors held at the Royal Society, London, on 28 September 1976 under the chairmanship of Sir Alec Merrison.) Pp 124 ISBN-0-85066-117-X (London Taylor and Francis, Ltd, 1977) £1 net

SCHMIDT, William G, and LaVEAN, Gilbert E (edited by) Communications Satellite Developments Technology (Progress in Astronautics and Aeronautics, Vol 42 Technical papers selected from the AIAA 5th Conference, subsequently revised for this volume) Pp xv+419 ISBN-0-915928-06-X (New York American Institute of Aeronautics and Astronautics, Cambridge, Mass and London The MIT Press, 1976)

SCHWARTZ, Ira R (edited by) Assisted by NAGAMATSU, Henry T, and STRAHLE, Warren C Aeroacoustics Fan Noise and Control, Duct Acoustics; Rotor Noise Pp xx[illegible]+634 ISBN-0-915928-09-4 (v 1) Aeroacoustics Stol Noise, Airframe and Airfoil Noise Pp xxxiv+443 ISBN-0-915928-08-6 (v 1) Aeroacoustics. Acoustic Wave Propagation, Aircraft Noise Prediction, Aeroacoustic Instrumentation Pp xxxiv+305 ISBN-0-925928-10-8 (v 1) (Progress in Astronautics and Aeronautics, Volumes 44, 45 and 46 Technical papers from AIAA 2nd Aero-Acoustics Conference, March 1975, subsequently revised for these volumes) (New York American Institute of Aeronautics and Astronautics, Cambridge Mass. and London The MIT Press, 1976)

TIEN, John K, and ANSELL, George S (edited by) Alloy and Microstructural Design (Materials Science and Technology) Pp xii+429 ISBN-0-12-690850-8 (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $39 50, £28 05

La VEAN, Gilbert, E, and SCHMIDT, William G (edited by) Communications Satellites Development Systems (Progress in Astronautics and Aeronautics, Vol 41. Technical papers selected from the AIAA 5th Conference, April 1974, subsequently revised for this volume) Pp xv+334 ISBN-0-915928-05-1 (New York American Institute of Aeronautics and Astronautics, Cambridge, Mass and London The MIT Press, 1976)

WHITT, Frank Rowland, and WILSON, David Gordon Bicycling Science Ergonomics and Mechanics Pp xiii+247 ISBN-0-262-23068-2. (Cambridge, Mass. and London The MIT Press, 1976) $4 95

YIH, Chia-Shun (edited by) Advances in Applied Mechanics, Vol 16 Pp xi+433 ISBN-0-12-002016-5 (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $39 50, £28 05

Earth Sciences

BAILEY, D K, and MACDONALD, R (edited by) The Evolution of the Crystalline Rocks Pp ix+484 ISBN-0-12-073450-8 (London and New York Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) £16, $35

BLYTH, F G H Geological Maps and Their Interpretation Pp 48 ISBN-0-7131-2568-3 (London Edward Arnold (Publishers), Ltd, 1976) £1 75 net

BURTON, J D, and LISS, P S (edited by) Estuarine Chemistry Pp xii+229 ISBN-0-12-147350-3 (London and New York Academic Press a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) £8, $17 50

CAMERON, Barry (edited by) Geology of Southeastern New England (A Guidebook with Articles, Bibliographies, and Field Guides for FieldTrips to the Boston Area and Vicinity) Pp 513 (Boston New England Intercollegiate Geological Conference, 1976) $8 Order from Dr Barry Cameron, Department of Geology, Boston University, Boston, MA 02215, USA

CAREY, S Warren The Expanding Earth (Developments in Geotectonics, 10.) Pp x+488 ISBN-0-444-41485-1 (Amsterdam, Oxford and New York Elsevier Scientific Publishing Company, 1976) Dfl 86, $34 50

MANTELL, C L, and MANTELL, A M Our Fragile Water Planet An Introduction to the Earth Sciences Pp ix+221. ISBN-0-306-30877-0 (New York and London Plenum Press, 1976)

RILEY, J P, and CHESTER, R (edited by) Chemical Oceanography, Vol. 6. Second edition Pp xiv+414 ISBN-0-12-588606-3 (London and New York Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) £14, $30 65

STIEGELER, Stella E A Dictionary of Earth Sciences Pp 301 ISBN-0-333-19435-7 (London and Basingstoke The Macmillan Press, Ltd, 1976) £5.95 net.

STIEGELER, Stella E A (edited by) Dictionary of Earth Sciences Pp 301. ISBN-0-333-19435-7 (London and Basingstoke The Macmillan Press, Ltd, 1976) £5 95 net

SUMMERSON, Charles H (edited by) Sorby on Sedimentology a Collection of Papers from 1851-1908 by Henry Clifton Sorby (Geological Milestones, Vol 1) Pp ii+225 (Miami, Florida The Comparative Sedimentology Laboratory, Division of Marine Geology and Geophysics, University of Miami, 1976)

SUMNER, J S Principles of Induced Polarization for Geophysical Exploration (Developments in Economic Geology, 5) Pp xiv+277 ISBN-0-444-41481-9. (Amsterdam, Oxford and New York Elsevier Scientific Publishing Company, 1976) Dfl 70, $27 95

WOOD, B J , and FRASER, D. G Elementary Thermodynamics for Geologists Pp xiii+303. ISBN-0-19-859927-7, (Oxford and London Oxford University Press, 1976) Boards £6 net, Paper £2 95 net.

Biological Sciences

ABBOTT, Isabella A., and HOLLENBERG, George J. Marine Algae of California Pp xii+827 ISBN-0-8047-0867-3. (Stanford, California Stanford University Press, 1976) $22.50

AINSWORTH, G. C. Introduction to the History of Mycology. Pp xi+359 ISBN-0-521-21013-5 (Cambridge, London and New York Cambridge University Press, 1976) £11 net

ANTONIADES, Harry N (edited by) Hormones in Human Blood Detection and Assay. Pp.xvii+810 ISBN-0-674-40635-4 (Cambridge, Mass and London Harvard University Press, 1976) £37.10

BANNISTER, P. Introduction to Physiological Plant Ecology Pp ix+273 ISBN-0-632-08980-6 (Oxford and London· Blackwell Scientific Publications, 1976) £4 75

BARBER, J (edited by) The Intact Chloroplast (Topics in Photosynthesis, Vol. 1.) Pp xi+476. ISBN-0-444-41451-7 (Amsterdam, New York and Oxford: Elsevier Scientific Publishing Company, 1976) Dfl 140, $55 95

BEARS. Their Biology and Management (Papers of the Third International Conference on Bear Research and Management, Binghamton, New York, U S A., and Moscow, U S S R , June 1974) Pp 467 (IUCN Publications, New Series, No 40) (Morges, Switzerland International Union for Conservation of Nature and Natural Resources, 1976.) US$12

BJORN, L O Light and Life Pp vi+249+19 plates ISBN-0-340-04966-0 (London, Sydney, Auckland and Toronto Hodder and Stoughton, 1977) Boards £3 45, Paperback £1 75

BOHART, R. M., and MENKE, A S In collaboration with H S Court, F D Parker, E E Grissell and D P Levin. Sphecid Wasps of the World· a Generic Revision Pp ix+695 ISBN-0-520-02318-8. (Berkeley, Los Angeles and London· University of California Press, 1976.) £34

Van den BOSSCHE, H. (edited by). Biochemistry of Parasites and Host-Parasite Relationships. (Proceedings of the Second International Symposium, Beerse, Belgium, 28 June—1 July, 1976 Organized by the Janssen Research Foundation) Pp xi+664 ISBN-0-7204-0592-0 (Amsterdam, New York and Oxford North-Holland Publishing Company, 1976) Dfl 135, $53 95

BOURNE, G H , and DANIELLI, J. F (edited by) Assisted by JEON, K. W International Review of Cytology, Vol 47 Pp 377. ISBN-0-12-364347-3 (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $32 50, £23.05.

BRIDGES, B A Bacterial Reaction to Radiation. (Microbiology Series) Pp 72 ISBN-0-904095-21-5 (Shildon, Co Durham Meadowfield Press, Ltd., 1976) £2 80

BRIGGS, D , and WALTERS, S. M Plant Variation and Evolution (World University Library) Pp 256 (New York and Toronto McGraw-Hill Book Company, London Cambridge University Press, 1976.) £2 95

BURNETT, J H Fundamentals of Mycology Second edition Pp xiii+673 ISBN-0-7131-2617-5 (London. Edward Arnold (Publishers), Ltd , 1976) £27 50

CALOW, Peter Biological Machines. a Cybernetic Approach to Life. (Special Topics in Biology Series) Pp viii+134 ISBN-0-7131-2583-7. (London Edward Arnold (Publishers), Ltd , 1976) Boards £7 95, Paper £3 95

CHEVALIER, Peter A (edited by) The Heart and Circulation (Benchmark Papers in Human Physiology/8) Pp xix+385 ISBN-0-87933-229-8. (Stroudsburg, Pennsylvania Dowden, Hutchinson and Ross, Inc , 1976 Distributed by Halsted Press, a Division of John Wiley and Sons, Inc , New York and London) £20; $33.

COBLEY, Leslie S An Introduction to The Botany of Tropical Crops. Second edition Pp xvi+371 ISBN-0-582-44153-6. (London and New York Longman, 1976) £6

CURIO, Eberhard The Ethology of Predation. (Zoophysiology and Ecology, Vol 7) Pp x+250. ISBN-3-540-07720-0. (Berlin and New York Springer-Verlag, 1976.) DM72; $29 60.

DEVERALL, Brian J Defence Mechanisms of Plants (Cambridge Monographs in Experimental Biology, No 19) Pp 110 ISBN-0-521-21335-5 (Cambridge, London and New York Cambridge University Press, 1977) £5 50

DOTY, Richard L. (edited by) Mammalian Olfaction Reproductive Processes, and Behaviour. Pp xi+344 ISBN-0-12-221250-9 (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $23 50, £16 70

DUDITS, D , FARKAS, G L , and MALIGA, P. (edited by) Cell Genetics in Higher Plants. (Proceedings of an International Training Course, 5-17 July, 1976, Szeged, Hungary.) Pp.xii+251 (Budapest. Akademiai Kiado, 1976) £8 69

EVELETH, Phyllis B , and TANNER, J M Worldwide Variation in Human Growth (International Biological Programme, 8) Pp xiv+498 ISBN-0-521-20806-8 (Cambridge, London and New York Cambridge University Press, 1976) £20

FASMAN, Gerald D (edited by), Handbook of Biochemistry and Molecular Biology Proteins Third edition Vol 1 Pp.427 ISBN-0-87819-504-1 (v 1) $57 50 Vol 2, Pp 789 ISBN-0-87819-505-X (v 2) $71 75 Vol 3 Pp 633 ISBN-0-87819-510-6 (v 3) $65 50 (Cleveland, Ohio CRC Press, 1976)

FEDIGAN, Linda Maris A Study of Roles in the Arashiyama West Troop of Japanese Monkeys (*Macaca fuscata*) (Contributions to Primatology, Vol 9) Pp vii+95. ISBN-3-8055-2334-3. (Basel, London and New York S. Karger, 1976) SFR /DM49, $19

FINNEGAN, David J Bacterial Conjugation. (Patterns of Progress Microbiology Series) Pp.42 ISBN-0-900-54193-8 (Shildon, Co Durham Meadowfield Press, Ltd , 1976.) £1 90

HASSELL, Michael P. The Dynamics of Competition and Predation (The Institute of Biology's Studies in Biology, No 72) Pp 68 ISBN-0-7131-25853. (London Edward Arnold (Publishers), Ltd , 1976) Boards £2 60, Paper £1 30

HEITEFUSS, R , and WILLIAMS, P H (edited by) Physiological Plant Pathology (Encyclopaedia of Plant Physiology, New Series, Vol 4) Pp xx+890 ISBN-3-540-07557-7 (Berlin and New York Springer-Verlag, 1976) DM194, $79 60.

HOGARTH, Peter J Viviparity (Studies in Biology No 75) Pp.66 ISBN-0-7131-2593-4. (London Edward Arnold (Publishers), Ltd , 1976 Boards) £3 net, Paper £1 50 net

JAMIESON, G A , and ROBINSON, D M (edited by) Mammalian Cell Membranes Vol 3 Surface Membranes of Specific Cell Types Pp 276. ISBN-0-408-70773-9. (London and Boston, Mass Butterworths, 1977) £18

Applied Biological Sciences

ALLISON, A C. (edited by) Structure and Function of Plasma Proteins, Vol. 2 Pp.xix+419 ISBN-0-306-35082-3 (New York and London Plenum Press, 1976) $7 40.

DeANGELIS, G G. Testing and Screening for Drugs of Abuse Techniques, Issues, and Clinical Implications. Pp viii+140 ISBN-0-8247-6417-X. (New York and Basel· Marcel Dekker, Inc , 1976) SFrs 60

ARIENS, E J (edited by) Drug Design, Vol 7 (Medicinal Chemistry. a Series of Monographs) Pp xv+295 ISBN-0-12-060307-1 (New York and London· Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976.) $30; £21 30

AUDUS, L J (edited by) Herbicides Physiology, Biochemistry, Ecology Second edition. Vol. 1 Pp xxi+608 ISBN-0-12-067701-6 £19, $48 Vol 2 Pp xx+564 ISBN-0-12-067702-4 £17 50, $38 25

BACCARANI, M (guest editor) Chronic Myelois Leukemia and Blastic Crisis. (Series Haematologica, Vol 8, 4) Pp 181 ISBN-87-16-02387-0 (Copenhagen Munksgaard, 1976) D kr 100.

BALTIMORE, David, BEARN, Alexander G , JERNE, Niels K , LEWONTIN, R C , NATHANS, Daniel, and VAGELOS, P Roy The Harvey Lectures, Series 70. (Delivered under the auspices of The Harvey Society of New York, 1974-1975) Pp xiv+202. ISBN-0-12-312070-5 (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $£15, £10 65

BEVERIDGE, W I B. Influenza The Last Great Plague An Unfinished Story of Discovery Pp xii+124. ISBN-0-435-62065-7 (London Heinemann Educational Books, Ltd , 1977) £2 95

BURNET, F M Immunology, Aging, and Cancer Medical Aspects of Mutation and Selection Pp 162 ISBN-0-7167-0490-0 (San Francisco W H Freeman and Company, 1976 (Hardcover $9 95, Softcover $6 50.

BRANDLY, C A , and CORNELIUS, Charles E (edited by) BEVERIDGE, W I B (guest editor) Advances in Veterinary Science and Comparative Medicine, Vol 20. Pp xii+322. ISBN-0-12-039220-8 (New York and London Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1976) $33 50, £23 80

CAMERON, H. M , LINSELL, D A , and WARWICK, G P. (edited by) Liver Cell Cancer. Pp xv+292 ISBN-0-444-41542-4 (Amsterdam, New York and Oxford Elsevier Scientific Publishing Company, 1976) Dfl 109, $43 75

Annual fluctuation of the pine elongation in Mt Kisokoma was also compared with annual fluctuation of the mean yield per acre of rice in Japan (Fig. 3). Rice yield per acre in Japan is affected mainly by sunshine and temperature of June, July and August. A similar trend of fluctuation is seen between pine growth and rice yield per acre of the previous year.

Study of *Pinus pumila*, may thus be useful in the estimation of past environmental changes such as fluctuations of temperature and sunshine.

Strong attenuation of Rayleigh waves in Tibet

THE Tibetan Plateau, which has an average elevation of 5.0 km over 7×10^5 km^2, is the largest topographic mass above sea-level on the Earth. Because it is covered with Cretaceous limestones[1] its uplift must be Tertiary, and is probably related to the Himalayan continental collision. There is considerable debate concerning its present structure and mode of formation. Various authors have theorised that Tibet was uplifted by underthrusting of a second crustal layer[2–6]; by horizontal compression and thickening[7–9], or by low-density material in the mantle[10]. All that is known with certainty is that it is isostatically compensated[11], and covered with widespread Neogene calc-alkaline volcanic rocks[12]. The study of Rayleigh wave attenuation reported here indicates that the lowermost part of the crust is partially molten, and that uplift has been due to horizontal compression.

Because of its size, uniformity and difficult access, Tibet is most easily studied using seismic surface waves. Rayleigh waves have the advantage that they are not confused with Love waves even if horizontal refraction causes the waves to arrive from an unknown direction. Because there are no long-period stations north of Tibet, however, the attenuation cannot be measured by using two stations on one raypath. Instead, we have compared Tibetan paths with other reference paths that do not cross the plateau (Fig. 1). By normalising the wave spectra at short periods, the azimuthal factor in the source spectrum can be cancelled approximately, and the spectral differences at longer periods can be ascribed to attenuation or scattering. We chose a period of 20 s for normalisation, because it is the average spectral peak on the seven reference seismograms. This method gives only a minimum value for attenuation, but records from the nuclear explosion of October 14, 1970 at Lop Nor give similar results without any normalisation.

Data from six earthquakes (yielding 14 Tibetan paths) are shown in Fig. 2. They were obtained by digitising the long-period vertical records from WWSSN stations at Kabul, Nilore, Lahore, New Delhi, Shillong and Hong Kong. Before differencing, the raw spectra $A(\omega)$ were smoothed by the operation:

$$\overline{A}(\omega) = \frac{\int_0^\infty A(\xi) \exp\left(-50\left(\frac{\xi-\omega}{\omega}\right)^2\right) \mathrm{d}\xi}{\int_0^\infty \exp\left(-50\left(\frac{\xi-\omega}{\omega}\right)^2\right) \mathrm{d}\xi}$$

On 11 of the 14 paths across Tibet, a large reduction in the amplitude of long period (40–50 s) Rayleigh waves is evident. This cannot be due to differences in the instruments (they are identical) or in the source spectrum or path length. They must result from different velocity structures under the stations, scattering or attenuation in Tibet.

The effect of the first is probably minimal, because all stations except Kabul are on stable continental crust of about 40-km thickness[13,14]. Selective reflection of long periods at the boundaries of Tibet is probably more important. The plateau is, however, bounded by mountain ranges (Himalayas and Kun Lun) in which the crustal thickness change is spread out over more than one wavelength. For such dipping interface problems, it has been found that reflection of Love surface waves is very small[15], so we do not believe that this effect accounts for the large spectral differences. These have been interpreted as the result of attenuation, so that:

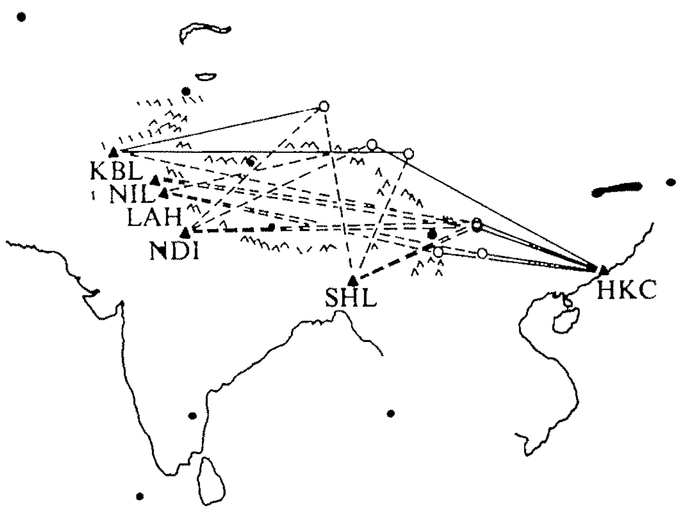

Fig. 1 Surface wave paths used to study attenuation. The Tibetan Plateau is outlined with mountain symbols; ○, earthquakes; ▲, stations, – – –, $Q_R(40) < Q_R(20)$; . . . . . ., $Q_R(40) > Q_R(20)$; ———, reference paths.

$$\min(Q_R^{-1}) = \frac{PG}{\pi\Delta} \ln\left[\frac{\overline{A}(\omega)\,\overline{A}_R(0.05)}{\overline{A}_R(\omega)\,\overline{A}(0.05)}\right]$$

where Q_R is the Rayleigh elastic quality factor, P is period, G group velocity, Δ the path length, and $A_R(\omega)$ the spectrum on the reference path.

The minimum attenuation obtained (Fig. 3) has a peak at 50-s period. The half-width of the peak is a factor of 2.8 in frequency, which is too narrow to be produced by frequency dependence of a geologically complex medium with various relaxation times, but is more likely to result from an increase of attenuation with depth, so that longer-period waves are more

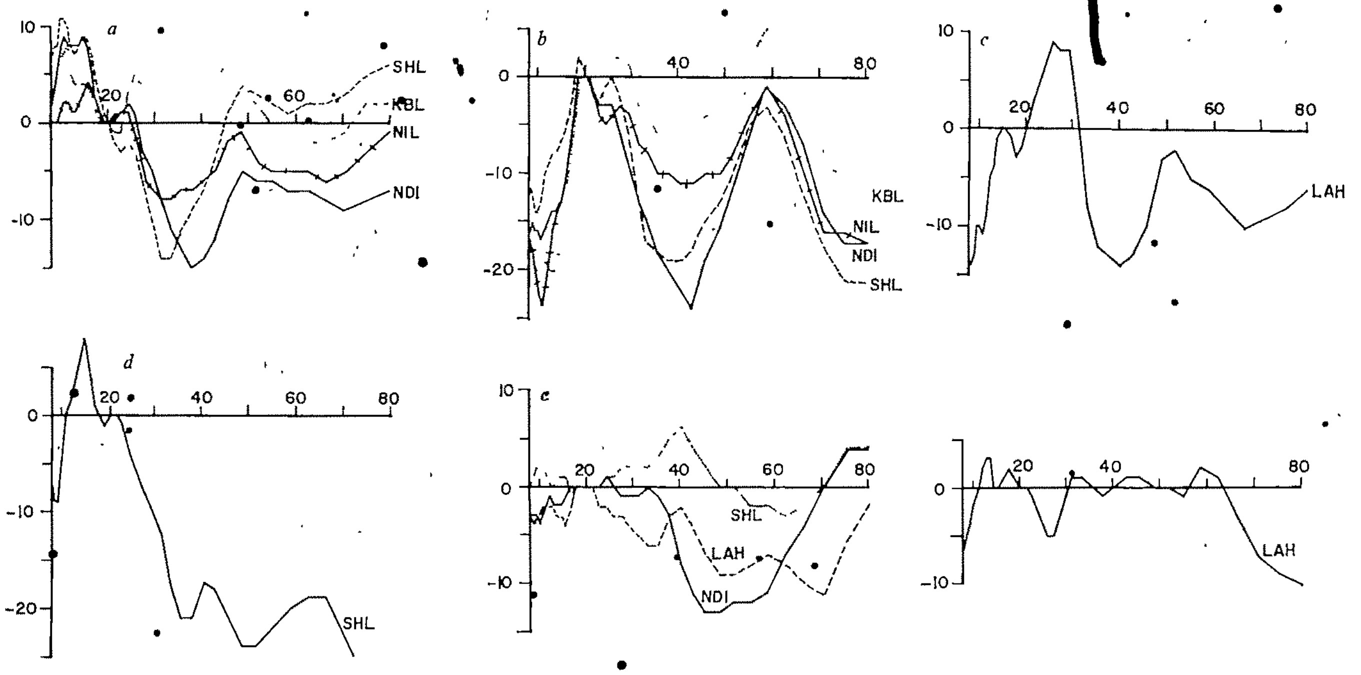

Fig. 2 Power spectrum differences in dB between Rayleigh waves crossing Tibet and those on reference paths from the same source. Period in s is given on the horizontal scale. The difference is set to zero at 20 s to normalise each curve. *a*, August 16, 1971 (1854 h), ref. HKC. *b*, August 16, 1971 (2237 h), ref. HKC *c*, February 5, 1966, ref. Fig. 3 Attenuation of Rayleigh waves determined from (*a*) nuclear test data and (*b*) all data combined. Bars show the s.d. in attenuation. ----, Single attenuating layer at 70-km depth. Attenuation goes to zero at 20-s period because of the normalisation performed.

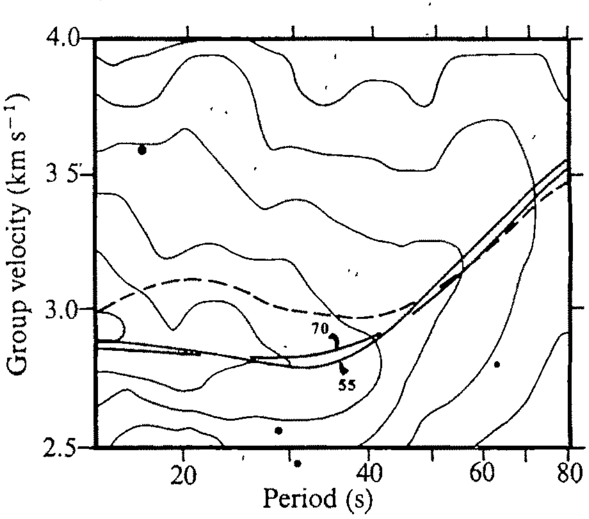
strongly affected. Assuming also that there are no purely dilatational dissipations, we can find the depth to the centre of the attenuating layer. Using an Earth velocity model compatible with observations on the group velocities of Rayleigh waves and the equations for a horizontally-layered Earth[16], we find that the best-fitting single attenuating layer would be centred at 70 km below the surface. Its 'attenuation thickness' (ratio of layer thickness to Q^{-1} for shear waves) is 2 km, that is, if the layer is 10 km thick, it has a Q of 5. Such extremely low values of Q are only found in two-phase (partially melted) rocks at such high pressures. There is, also, a suggestion of a second, deeper attenuating layer in the data (Fig. 3), which is not discussed here because it is so poorly resolved.

The geological significance of the inferred partially-molten layer depends on whether it is in the crust or the mantle. From the size of the gravity anomaly[11] we can estimate that the crust is between 55 km thick (if the mantle is as hot and light as it is beneath mid-ocean ridges) and 70 km thick (assuming a normal mantle[17]). Either of these thicknesses is compatible with the group velocity data (Fig. 4) because the lower crustal shear velocity is unknown. The velocity required in the 70-km model

Fig. 4 Rayleigh wave group velocity data from 20 paths consisting of at least 50% Tibetan Plateau. Records were analysed by spectral amplitude technique[18] and the spectral amplitudes have been summed. Total power is contoured in 5-dB intervals, and the shaded area indicates a swath within 2 dB of the local maximum. ———, Models with crustal thicknesses of 55 and 70 km. ----, Model with two normal continental crusts superposed.



(3.8 km s^{-1}) is more plausible, however, than the very low velocity required in the [illegible]5-km model (3.5 km s^{-1}). Also, the volcanics at the surface are clearly of crustal origin[8], and it is natural to associate the attenuating layer with their source region.

We conclude that Tibet has a crust of about 70-km thickness, of which the lowermost part is partially molten. The inferred high temperature of the Moho is inconsistent with the crustal-underthrusting model for the formation of Tibet[9] It is suggested that the high temperatures may predate the Himalayan continental collision, and that they may have been responsible for extensive horizontal compression in Tibet after that collision, thus explaining the anomalously thick crust. At present, Tibet overlies an asthenosphere which extends into the lower crust, precluding any long term mechanical strength. This weakness at shallow depths is responsible for the uniformity of Tibetan elevations over wide areas in the centre of an orogenic zone.

African Archaean mobile belts and granite–greenstone terrain

ARCHAEAN granite–greenstone terrains such as the west African and Rhodesian Cratons, are frequently bordered by pene-contemporaneous, long-lived, high-grade mobile belts containing granulite facies supracrustals, enderbites, granite gneisses and anorthosites. For example, in Sierra Leone[1], the granite–greenstone terrain contains low-grade supracrustal belts along NNE–SSW trends, while the discordant Kasila Group granulite facies belt trends NW–SE, and forms the coastal border of the West African Craton. A similar relationship is found between the Rhodesian and Kaapvaal Cratons, which are separated by the east–west trending Limpopo Belt[2,3] The metamorphic, structural and lithological contrasts between mobile belts and granite–greenstone terrain have been ascribed to contrasts in heat-flow regime. I attempt here to correlate field and experimental data to elucidate Archaean mobile belt–craton relationships.

Greenstone belts were probably initiated along linear 'rift-type' structural weaknesses which developed as a consequence of tensional forces within the lithosphere at right angles to their trend[4] These forces could be caused by drag from an underlying upwelling asthenosphere, as for example, in present-day axial rift zones in continental swells and mid-ocean ridges. The scale of contemporary mantl 'convection' cells and associated orogenic belts is similar to that of the mobile belts, but dwarfs the dimensions and periodicity of the Archaean greenstone belts. Experiments[5,6] show that convection leads to the formation of bimodal structural patterns; where convection cells may be primary or secondary, each having contrasting dimensions and orientations. I propose here that mobile belts represent 'super-greenstone belt' structures due to primary linear asthenospheric upwellings, whereas secondary upwellings (Richter rolls) give rise to greenstone belts, usually at a high angle to the trend of the primary structure. The initial primary upwelling divides the pre-greenstone terrain crust into two portions, separated by a zone which undergoes greenstone belt evolution that outstrips that of the relatively sluggish belts within the adjacent cratons (Fig 1) This contrast in evolution rate and scale between mobile belts and greenstone terrain is due to respective differences in heat transfer from the underlying asthenosphere

Fig. 1 Oblique view and section of an idealised granite–greenstone–mobile belt relationship.

Heat production and transfer within the Archaean asthenosphere and mesosphere was probably more than twice its present value[4], and may have involved turbulent, rather than steady-state convective cells[5]. Elder[8] has also shown that within a convecting system there is a critical lateral distance between the mobile belt and the development of secondary linear systems. In the African Archaean cratons the greenstone belts associated with the secondary cells are frequently enveloped by the deforming marginal zones of the mobile belt[2] indicating that this critical distance was small This distance is governed by the loss of heat from the upper surface of the primary cell, which is the asthenosphere–lithosphere boundary, and the thickness of the convecting asthenosphere layer. Highly efficient loss of heat to the lithosphere could have arisen by convection within its granitic layer[7], since convective diapirs of granite frequently distort the originally linear trend of the secondary cells to produce the less ordered structure typified by the 'gregarious batholith'. Elder also noticed that natural breaks occurred within the secondary cells, which could explain the longitudinal impersistency of some supracrustal belts.

The granulite facies mobile belts are characterised by linear and dome–basin tectonic styles, where extreme deformation in the linear portions limited grain growth, and produced fine-grained basic granulites and platy quartzo-feldspathic rocks. The relative movement of the bordering cratons with respect to the mobile belt, by pure and/or simple shear, is responsible for the plastic deformation in belts and the development of thrusts at their margins. The cause of the movement may be due to small angular shifts in the orientation of the bordering cratons, as they succumb to the eddy currents in the underlying turbulently convecting asthenosphere.

The high heat flow in the mobile belt may also be the key to the close spatial and temporal relationships between granulite facies rocks and layered calcic anorthosites[4]. Anorthosites occur within and adjacent to mobile belts, and are characteristically coarse-grained, even pegmatitic, suggesting intrusion of a hydrous magma into hot crust. The restricted occurrence of layered calcic anorthosites within the Archaean[4], and of most massif-type anorthosites to mobile belts of Proterozoic age, suggests that they are formed within zones of extremely high heat flow Phanerozoic anorthosites are also restricted to zones of high heat flow where lithospheric plates have[8] or are separating[9].

Ensialic Proterozoic belts[10], and those of the Pan-African, may be caused by processes similar to those of Archaean age. The post-Archaean lithosphere, however, was relatively thicker, stronger and more sedate[11], failing to allow the formation of secondary structures, so that greenstone belts did not form contemporaneously with mobile belt activity. Phanerozoic 'plate tectonics' may represent the final examples of a decaying process now only capable of producing endosialic orogens on the margins of continental lithosphere resistant to mobile belt formation.

I thank the Diamond Corporation of West Africa for finance, and R. A. Williams for discussions.

Isolation of amitrole-degrading bacteria

THE herbicide, amitrole (3-amino-1,2,4-triazole) is degraded in soil within a matter of weeks under favourable conditions[1–4]. This degradation may be microbiological since it is negligible in soils sterilised by steam[1–3,5] or chemicals[2,3]. Kaufman *et al.*[6], however, consider amitrole breakdown to be primarily due to chemical processes since amitrole-degrading organisms have never been isolated from soil. They found that degradation of amitrole continued in chemically sterilised, though not in autoclaved soil. We report here the isolation of amitrole-degrading microorganisms from soil, thus strengthening the case for microbial degradation.

Tenfold serial dilutions (from 10^{-2} to 10^{-8}) of a sandy clay loam soil were prepared in each of three media: basal medium (0.03 g K_2HPO_4, 0.01 g $MgSO_4.7H_2O$ and 30 p.p.m. amitrole, pH 7 3), medium 2 (basal medium plus 3% sucrose) and medium 3 (basal medium plus 3% sucrose, 50 p.p.m. $(NH_4)_2SO_4$, 100 p.p.m. peptone and 20 p.p.m. yeast extract). The test-tubes of inoculated media were incubated at 25 °C over 6 weeks and the amitrole content in those with visible growth was measured by Sund's method[7]. Amitrole disappeared completely in medium 2 at soil dilutions of 10^{-3} to 10^{-6} (Table 1), but no degradation could be detected in any other treatment

Pure cultures were isolated from tubes showing degradation by dilution plating on to the same medium solidified with 1.5% agar. Of 36 representative isolates reinoculated into medium 2, 10 were capable of degrading amitrole; nine of these were Gram-positive rods (*Bacillus* spp. and *Corynebacterium* spp.) and one was identified as *Pseudomonas* sp.

Table 1 Degradation of amitrole by soil samples

Soil dilution	Incubation time (weeks) 1	2	3	4	5	6
10^{-2}	–	–	–	–	–	–
10^{-3}	–	–	+	+	+	+
10^{-4}	–	–	–	+	+	+
10^{-5}	–	–	–	–	–	+
10^{-6}	–	–	–	–	–	+
10^{-7}	–	–	–	–	–	–
10^{-8}	–	–	–	–	–	–

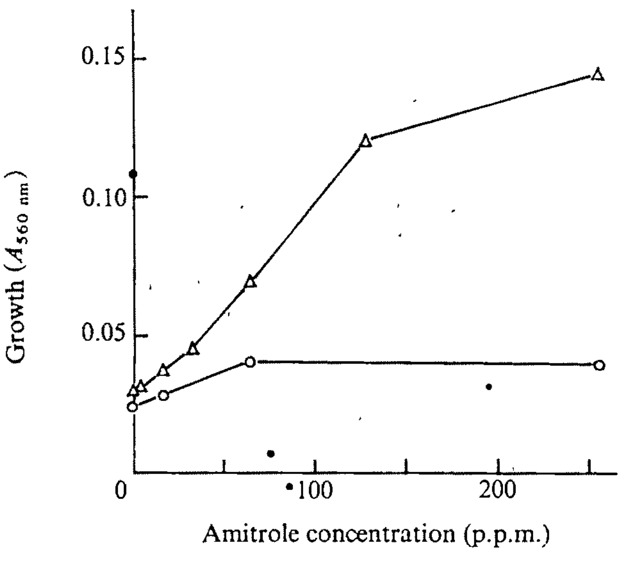
Diluted soil samples were incubated in 10-ml aliquots of medium 2 at 25 °C; –, no degradation; +, degradation.

The relationship between growth of one amitrole-degrading isolate and amitrole concentration was determined by growing the isolate in Erlenmeyer flasks of basal medium or medium 2 containing various amitrole concentrations. To prevent aerial contamination of the medium with combined nitrogen, each flask was sealed with a rubber stopper and connected with the exterior only by a U-tube containing H_2SO_4. In these conditions the isolate was unable to fix molecular nitrogen.

Growth was roughly proportional to herbicide concentration up to 256 p.p.m. amitrole in the medium with sucrose (Fig 1). There was little growth in basal medium with amitrole as the sole source of organic carbon as well as nitrogen.

The inability of other workers to isolate actively degrading organisms may have been due to their use of enrichment media with amitrole as sole source of organic carbon rather than nitrogen. It also seems that the decomposition of amitrole is inhibited in soil dilutions less than 1 in 1,000. This could be due to preferential use of other nitrogen

Fig. 1 Effect of amitrole concentration in the medium on growth of isolate Q_8 after incubation for 17 d at room temperature (20 °C average ± 6 °C). Mean of three replicates, in basal medium (○) and medium 2 (△)



sources present in soil since the presence of combined nitrogen in medium 3 prevented degradation of amitrole at any soil dilution.

We thank the Rural Credits Development Fund and the University of Sydney for financial support, and Amchem for a gift of high purity amitrole.

Frequency of heavy-metal resistance in bacteria from inpatients in Japan

IN many bacteria, resistance to heavy metals is associated with a plasmid[1–4]. R plasmids in *Escherichia coli* can determine resistance to several metallic ions such as mercury, cobalt and nickel[3], and a penicillinase plasmid mediating resistance to mercury, cadmium, arsenate, arsenite, lead and zinc has been observed in *Staphylococcus aureus*[1,2]. Mechanisms controlling bacterial resistances to mercury and cadmium are quite different although both are mediated by the same penicillinase plasmid[4]. Furthermore, microorganisms generally detoxify mercurial compounds metabolically by the formation of volatile mercury[5–9] or mercury mercaptides[10–12]. It is of interest that resistance to these heavy metals is mediated by the plasmids which determine resistance to antibiotics Most of these heavy metals are established or possible causes of environmental pollution, methyl mercury causes 'Minamata disease'[13,14] and cadmium causes 'Itai-Itai disease'[15,16] in Japan. The role of R plasmids in drug resistance has been widely studied[17–21], and extrachromosomal determinants are a main cause of the increase in numbers of drug-resistant bacteria. Studies of heavy metal resistance have attempted to establish a relationship between resistance to heavy metals and to drugs in the hospital environment[22,23] The factors selecting for these heavy-metal-resistant bacteria have not yet been identified. We believe that heavy-metal-resistant microorganisms do not arise by chance, but, that there must be selectional factors beyond mere drug resistance. One of these selectional factors may be environmental contamination by heavy metals. To investigate this possibility, we studied the frequency of drug and heavy-metal resistance in clinical isolates of *E. coli*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa* and *S. aureus*. We report here that the frequency of heavy-metal resistance in these strains was the same as, or higher than that of antibiotic resistance. Some R plasmids in *E. coli* and *K. pneumoniae* also carried a resistance to Hg.

Figure 1 shows the distribution curves of Hg, Cd, As and Pb resistances (from agar dilution tests), in 564 strains of *E coli*, 331 strains of *K. pneumoniae*, 787 strains of *P aeruginosa* and 515 strains of *S aureus*. The distribution of susceptibility to most of these heavy metals, against which a resistance developed, is bimodal. But in the case of a Cd resistance in *S aureus*, there were three groups of Cd sensitivity.

The frequency of a resistance to these heavy metals and to several drugs for the tested strains is shown in Table 1. The frequency of the heavy-metal-resistant strains was the same as, or higher than the frequency of drug-resistant strains. Many strains were resistant to heavy metals, but remained sensitive to the antibiotics (21.6% of *E. coli*, 27 2% of *K. pneumoniae*, 19.5% of *P. aeruginosa* and 8.0% of *S. aureus*).

We selected 348 strains of *E. coli* and *K. pneumoniae* resistant to Hg and examined the conjugal transferability of their resistance by using two recipients. One recipient, *E. coli* K12 ML1410-Nx, a nalidixic acid-resistant mutant and an As-sensitive segregant of *E. coli* K12, was used for the transfer of R plasmids in the first cycle. The other recipient, *E coli* JE17-Rif, isolated in our laboratory, is a rifampicin-resistant mutant and was used for the second cycle of transconjugation. Both recipients are sensitive to Hg, As, streptomycin (SM), tetracycline (TC), chloramphenicol (CM), kanamycin (KM) and gentamicin (GM) but resistant to Cd. Among 231 strains of Hg-resistant *E. coli*, 207 Hg-resistant R plasmids were isolated, and of these 195 were As resistant. Among 117 Hg resistant *K pneumoniae*, 110 R plasmids carrying an Hg resistance were also observed: 102 of these 110 R plasmids carried resistance to As. In *E. coli*, R plasmids with a resistance to R(Hg,As; SM,TC,CP,KM) were isolated most frequently, followed by R(Hg,As, SM,TC,CP), R(Hg,As, SM,KM), R(Hg,As, TC,CP) and R(Hg,As, SM,TC,KM), in that order. A similar result was obtained in *K. pneumoniae* The resistance patterns of R plasmids were similar to those of the resistant strains that were frequently isolated, showing that Hg resistance in these enterobacteria is mainly due to the presence of R plasmids (Table 2).

Transferable R plasmids carrying Hg resistance were present in

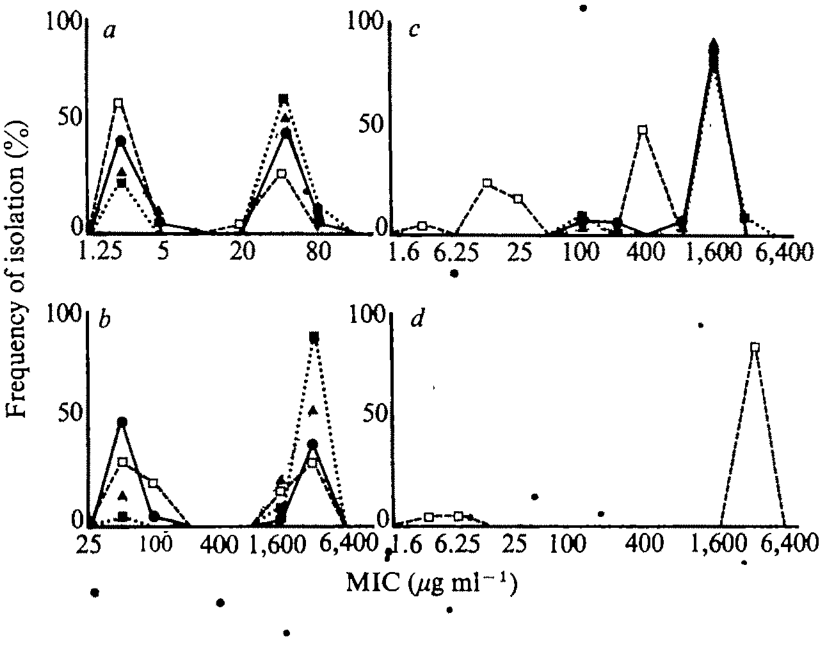

Fig. 1 The minimum inhibitory concentration (MIC) distribution curves of *a*, Hg, *b*, As, *c* Cd and *d*, Pb resistances (by agar dilution test) for 564 strains of *E. coli* (●), 331 strains of *K pneumoniae* (▲), 787 strains of *P aeruginosa* (■) and 515 strains of *S. aureus* (□). The tested strains were isolated in the Clinical Laboratory of the Jikei Hospital between 1974 and 1976 The metals, Hg, Cd, As and Pb were used as $HgCl_2$, $CdCl_2$, Na_2HAsO_4 and $Pb(CH_3COO)_2$, respectively Nutrient agar was used for the metal resistance test because $HgCl_2$ was stable in it The distribution curves of Hg, Cd and As resistances show the clear-cut distinctions between the 'sensitive' and 'resistant' populations, except that the Cd resistance in *S aureus* is divided into three groups In the case of the Pb resistance in *S. aureus*, the distribution pattern clearly revealed two peaks In *E coli*, *K. pneumoniae* and *P aeruginosa*, the distribution curves indicated that the resistance concentrations of each metal were 10 μg ml^{-1} for Hg, 400 μg ml^{-1} for Cd and 400 μg ml^{-1} for As In *S. aureus*, the resistance concentrations of Hg, As, Pb, high and intermediate Cd were 10 μg ml^{-1}, 400 μg ml^{-1}, 100 μg ml^{-1} and 10 μg ml^{-1} respectively.

†Hg $HgCl_2$, Cd $CdCl_2$, As Na_2HAsO_4, Pb $Pb(CH_3COO)_2$

‡High Cd 258 (50.1%), intermediate Cd 233 (45.2%)

§We cannot detect Pb-resistant strains since the distribution pattern of Pb resistance shows only one peak

**Streptomycin(SM), tetracycline(TC), chloramphenicol(CP), kanamycin(KM) and gentamicin(GM) were at a final concentration of 12.5 μg ml^{-1} for the selection of resistant strains in *E. coli*, *K. pneumoniae* and *S. aureus*. In *P. aeruginosa*, cultures not inhibited by 200 μg of SM, TC, CP and KM per ml or 25 μg of GM per ml were regarded as resistant to each of the drugs. In *S. aureus*, resistance concentrations of penicillin(PC), erythromycin(EM) and josamycin(JM) were 1.6 IU ml^{-1} 25 μg ml^{-1} and 25 μg ml^{-1}, respectively. ND, not determined.

most (89.6% of *E. coli* and 94.0% of *K. pneumoniae*) of the Hg-resistant isolates. It should be noted that there were three R plasmids carrying only Hg and As resistance in *K. pneumoniae*. These three R plasmids were quite stable in both *E. coli* K12 ML1410-Nx and *E. coli* JE17-Rif (Table 2). This is of interest as mercury is an environmental pollutant.

Thus, frequency of a heavy-metal resistance was the same as, or higher than, that of an antibiotic resistance, and many isolates were heavy-metal resistant but drug sensitive. We isolated 317 R plasmids with an Hg resistance from Hg-resistant *E. coli* and *K. pneumoniae* (91.1% frequency). In addition, 297 R plasmids mediated As resistance.

This work was supported by the Japanese Ministry of Education.

Permanent segmental interchange complex in the termite *Incisitermes schwarzi*

IN a cytogenetic survey of the termites of Florida, we have found two species, *Incisitermes schwarzi* (Banks) and *Kalotermes approximatus* (Snyder) (Isoptera; Kalotermitidae), that possess segmental interchange complexes as a regular feature of their breeding system. This report is concerned with the chromosomes of *I. schwarzi*, which has the most extensive complex of reciprocal translocations so far described in any animal species. The complex involves about half of the chromosome set, and is restricted to males. The occurrence of this interchange complex may be related to the social organisation of these insects, to an inbreeding habit of reproduction, or to the evolution of a mechanism of sex determination with multiple sex chromosomes.

The diploid number for both males and females is 32; the chromosome complement contains 4 or 5 acrocentric pairs, the remainder being metacentric or submetracentric. In female meiosis there are 16 bivalents; most of them are ring-shaped, indicating the presence of a terminal chiasma in each chromosome arm (Fig. 1*a*). In male meiosis in 7 of the 8 colonies studied, there were 9 bivalents plus a ring of 14 chromosomes (Fig. 1*b*). (The males of one colony had 8 bivalents plus a ring of 16 chromosomes; see Fig. 2.) All of the males from any one colony had the same chromosome configuration. The ring of 14 seems to be composed of metacentrics and submetacentrics; the chiasmata are terminal or nearly terminal. Judging from the chromosome numbers in anaphase I groups and in second meiotic divisions, disjunction from the ring in the first meiotic division seems to be regular, half of the chromosomes moving to one pole, half to the other.

The restriction of the ring to male meiosis indicates that the male is the heterogametic sex, and that the sex chromosomes are incorporated into the ring. Although we have not yet identified the sex chromosomes in this species, this interpretation is supported by the observation that the sex ratio is approximately 1 : 1 (suggesting chromosomal determination of sex), and by the finding that in the related species *K. approximatus*, where the sex chromosomes can be more easily distinguished morphologically, they are indeed part of the ring. On this interpretation the males of *I. schwarzi* may have, in addition to one 'standard' set of autosomes and an X chromosome, six interchange autosomes and a neo-Y chromosome that evolved from an original standard set and an original Y by a series of reciprocal translocations. Alternate disjunction from the ring of 14 chromosomes formed at meiosis would ensure that the interchange autosomes would always be transmitted to the progeny along with the male-determing neo-Y chromosome (Fig. 3). An alternative possibility is that the

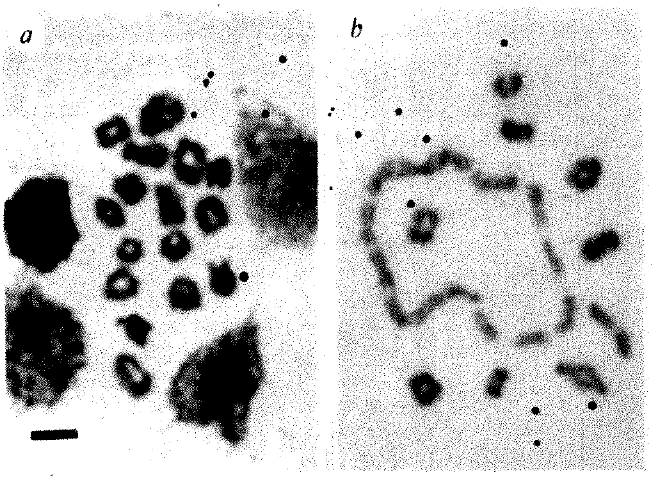

Fig. 1 Meiotic chromosomes in *I. schwarzi*. *a*, female; *b*, male. Whole termite colonies were collected from various locations in southern Florida (Fig. 2), and maintained in the laboratory on a mixture of paper towels and sawdust from termite-infested wood. Chromosome preparations were usually made within a month of collecting the colony. Gonads from winged imagoes were dissected out in 0.45% sodium citrate solution, treated for 3 min with 1.0 N HCl at about 60 °C, transferred to 45% acetic acid for 15–20 min, squashed on a slide under a coverslip, rinsed in distilled water, air-dried, and stained with Giemsa (bar, 5 μm).

Fig. 3 Diagram illustrating the hypothetical association of a neo-Y and interchange complex (shaded) with the X and the standard set of chromosomes (unshaded) in the male. *a*, Mitotic chromosomes; chromosome ends are numbered to show an example of segmental interchanges that would lead to ring formation in meiosis (*b*). The sizes of the chromosomes are arbitrary; the X and Y chromosomes have not yet been distinguished from the autosomes nor from each other in this species.

whole interchange complex is a set of multiple, male-determining, sex chromosomes.

Such extensive reciprocal translocations, ordinarily expected to lead to chromosome imbalance in gametes and lethality in zygotes, evidently form part of a balanced system that has adaptive value for the species, as in the case of the more extensive exchanges found in the plants *Oenothera* (ref. 1) and *Isotoma* (ref. 2). It is premature to speculate in detail on the genetic and evolutionary significance of the interchange complex in *I. schwarzi*, but the following comments point up some of its implications.

An important genetic consequence of the interchange complex is that its chromosomes, and the standard set with which it is associated, behave as a single linkage group in the male; the interchange complex therefore tends to reduce the genetic variability that would otherwise result from independent assortment of the chromosomes involved. Interchange complexes similar to that found in *I. schwarzi* also occur in the males of the dioecious plant *Viscum* (refs 3, 4), the beetle *Cyrsylus volkameriae* (ref. 5), some populations of the flea *Nosopsyllus fasciatus* (ref. 6), and some species of the centipede *Otocryptops* (refs 7, 8); and possibly in some females of the freshwater copepod *Diaptomus castor* (refs 9, 10). The interchange complex in each of these cases might represent an example of the evolution of a system of multiple sex-determining chromosomes; or it may have arisen by a series of translocations between the Y chromosome of a simpler sex-determining system and the autosomes, as a means of reducing variability, or of maintaining heterozygosity, in a set of autosomal genes. The genetic effect of the interchange complex in all these organisms may be related to the reduction of crossing-over that occurs in the heterogametic sex of other organisms, notably in the males of the fruit fly *Drosophila* and in the females of the silkworm *Bombyx*.

The presence of the interchange complex might be important in the evolution of sociality in these termites, similar in its reduction of genetic variability to the systems of parthenogenesis and male haploidy that characterise the other social insects, the ants, bees and wasps[11]. The colony might provide a more uniform and stable environment, so that more genetically uniform individuals would be favoured; evolution of genetic uniformity might also be a necessary condition for the coevolution of the intricate hormonal and behavioural interactions that take place among the individual members of the colony. (Note, however, that while *I. schwarzi* and *K. approximatus* both have extensive interchange complexes, other species of termites—*Termopsis angusticollis* (ref. 12), *Reticulitermes flavipes* (ref. 13), *Odontotermes redemanni* (ref. 14) and *Neotermes jouteli* (unpublished observations)—do not.)

The presence of an interchange complex in *I. schwarzi* may be the evolutionary consequence of inbreeding. The interchange complexes of *Oenothera* and *Isotoma* are associated with a self-pollinating habit of reproduction[1,2]; Darlington and La Cour[15] obtained evidence in the plant *Campanula* that selfing and inbreeding favour, at least transiently, the maintenance of interchange complexes; and Lewis and John[16] found interchange complexes in some isolated populations of roaches. In termite species in general, the reproductives that appear in the mature colony, at the time of swarming, are usually siblings. Because they are weak fliers and may not travel far from the original colony, and since in any case different colonies in an area may swarm at different times[17], new colonies in general are probably founded by two siblings from the same original colony, rather than by a male and a female from different colonies. These termites therefore may be highly inbred, and thus might provide another example of the correlation between inbreeding on the one hand and the evolution and maintenance of structural heterozygosity on the other.

Note added in proof: We have recently found a third termite species that has an interchange complex in male meiosis: *Neotermes castaneus* (Burmeister) (Kalotermitidate).

Parallel variation at an enzyme locus in sibling species of field crickets

ELECTROPHORETIC surveys of levels of heterozygosity in animal species have established that populations often contain large amounts of genetic variation at loci coding for soluble proteins[1–3]. This has led to an extended debate about the causes of such variation. In particular, two opposing views have emerged, one emphasising the importance of balancing selection in maintaining the protein variation (selectionist) and the other emphasising the importance of stochastic processes (neutralist)[4–6]. Here I examine spatial patterns of variation at a single enzyme locus in two closely related insect species. I argue that since these sympatric species not only have similar mean frequencies of particular electrophoretic variants, but also exhibit a common pattern of geographic variation, parallel selection provides the only satisfactory explanation.

As attempts to distinguish between the neutralist and selectionist hypotheses, studies of spatial patterns of variation have often proved to be ambiguous. In the absence of independent and accurate estimates of mutation rate, effective population size, gene flow or (in the case of interspecific comparisons) time since divergence, both neutralist and selectionist arguments are sufficiently flexible to explain most observed patterns of variation. Moreover, since allelic variants can have identical electrophoretic mobility, electrophoretically detectable variation may represent only a fraction of the total variation[7-10]. A single electrophoretic mobility class ('electromorph'[11]) may include many alleles with common mobility. Indeed, heterogeneity within single mobility classes has been demonstrated in several enzyme systems[10,12-14]. Recognising this possibility, recent models which consider the behaviour of slightly deleterious alleles suggest that similarity of electromorph frequencies among apparently isolated populations or species may reflect independent approximations of the same mutation–selection equilibria rather than the effects of balancing selection[11,15,16]. But the observation that electromorph frequencies vary in parallel in two sympatric species can only be explained by the latter hypothesis. Previous studies of enzyme variation in mussels[17] and fish[18] have documented possible examples of parallel response to environmental factors.

Gryllus veletis and *Gryllus pennsylvanicus* are sibling species of field crickets (Orthoptera, Gryllidae) found together in southern Canada, throughout the north-eastern United States, and south in the Appalachian Mountains to North Carolina[19-22]. They are exceedingly similar morphologically, have identical calling songs and are found in identical habitats[19,21]. They can be distinguished only on the basis of differences in their life cycles[20-25]. *G. veletis* undergoes diapause as a late instar nymph and matures in May and June. *G. pennsylvanicus* undergoes diapause in the egg stage and adults appear in late summer.

Table 1 Mean PGI electromorph frequencies in *G. veletis* and *G. pennsylvanicus*

Electromorph	*G. veletis*	*G. pennsylvanicus*
PGI^{160}	0.001	—
PGI^{135}	0.040	0.105
PGI^{125}	0.046	0.019
PGI^{100}	0.804	0.797
PGI^{65}	0.097	0 079
PGI^{25}	0.010	—
n	40	52

Each value represents the unweighted mean of electromorph frequencies in 11 populations from the eastern United States. $\bar{n}$ is the average sample size (number of individuals). Localities are described in Fig. 1. The most common electromorph is designated 100 and other electromorphs are given numbers corresponding to their relative mobilities. Crickets were frozen soon after collection and stored at −80 °C. They were thawed immediately before electrophoresis, the head and wings were removed and soluble proteins were extracted by homogenising legs, thorax and abdomen in 0.4–0.6 ml of 0.1 M Tris, 0.001 M EDTA, 5×10^{-5} M NADP, *p*H 7.0. Electrophoresis of phosphoglucose isomerase was on 12% starch gels using the discontinuous LiOH buffer of Selander *et al.*[26].

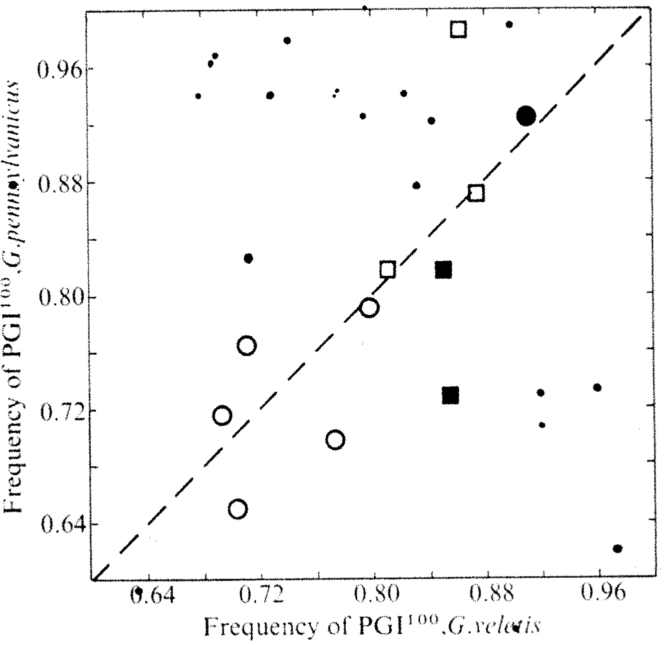

Fig. 1 Frequencies of PGI^{100} in sympatric populations of *G. veletis* and *G. pennsylvanicus*. Each point represents a single collecting locality. Some localities were sampled in 1974, others in 1975. In no case, however, have data from more than 1 yr been combined. Along the dashed line electromorph frequencies are equal in the two species. $r_s = 0.82$, $P < 0.01$. r_s is the Spearman rank correlation coefficient. Localities: ○, Tompkins Co., New York; ●, Litchfield Co., Connecticut; □, Augusta Co. and Rockbridge Co., Virginia; ■, Alleghany Co., North Carolina.

Using starch gel electrophoresis combined with histochemical staining, I examined patterns of variation at 17 loci in *G. veletis* and *G. pennsylvanicus* for evidence of parallel variation in electromorph frequency. Of these 17 loci, nine are essentially monomorphic in both species. Of the polymorphic loci, phosphoglucose isomerase (PGI) is unique in having nearly identical mean electromorph frequencies in the two species (Table 1). Analysis of PGI phenotypes in parents and offspring from single-pair matings confirm that the observed variation is genetic. Zygotic frequencies among the progeny are always consistent with segregation patterns predicted from the presumed parental genotypes (Table 2).

To test for the possibility of parallel variation at the PGI locus, I plotted the frequency of the most common electromorph, PGI^{100}, in eleven populations of *G. pennsylvanicus* against the frequency of the same electromorph in sympatric populations of *G. veletis* (Fig. 1). Samples were taken in the late spring (*G. veletis*) or late summer (*G. pennsylvanicus*) of 1974 and 1975. For each data point late instar nymphs or adults of both species were collected from identical localities. There is an obvious correlation in electromorph frequency ($r_s = 0.82$, $P < 0.01$, Spearman rank correlation coefficient). Moreover, the data points fall

Table 2 Genetic crosses of phosphoglucose isomerase variants in *G. veletis* and *G. pennsylvanicus*

			Observed (expected*) No. of each phenotype among progeny

close to the line of equal frequency; that is, the frequency of PGI^{100} tends to be the same in sympatric populations of the two species in spite of significant differences in electromorph frequency between allopatric populations of the same species. A plot of PGI^{65} frequencies in the same sympatric populations of *G. veletis* and *G. pennsylvanicus* also yields a significant correlation ($r_s = 0.66$, $P < 0.05$).

All the collecting localities (including those within the same county) are thought to represent distinct populations. Both cricket species are predominantly short-winged (more than 99% in the populations examined), and dispersal by flight is rare. Evidence from mark-recapture studies indicates that adults do not disperse very far on foot, even within areas of favourable habitat. Moreover, among populations of *G. veletis* and *G. pennsylvanicus* from Tompkins County, New York, three of five polymorphic loci in each species exhibit significant heterogeneity in electromorph frequency (my unpublished results).

Hybridisation and introgression between the two cricket species cannot be invoked to explain the data. In spite of repeated attempts, hybrid progeny have never been produced in laboratory matings[20–22,27]. Furthermore, I have found that natural populations of *G. veletis* and *G. pennsylvanicus* are fixed for different electromorphs at the phosphoglucomutase-1 locus. No heterozygotes have been detected among 266 *G. veletis* and 206 *G. pennsylvanicus* examined.

The environmental factors responsible for the observed pattern of variation have not been identified. The correlation in electromorph frequencies, however, is in large part due to parallel changes in mean electromorph frequency between crickets from different geographic areas (Fig. 1). *G. veletis* and *G. pennsylvanicus* from Tompkins County, New York, have significantly lower frequencies of PGI^{100} than populations from the mountains of Virginia. Crickets from Litchfield County, Connecticut, have distinctly higher frequencies of that electromorph. Superimposed on the regional pattern is considerable local variation. Although possibly due to selection, local variation may also result from random differentiation in relatively small populations with low interpopulation dispersal rates.

Two important questions remain unanswered. First, do the PGI^{100} and PGI^{65} electromorphs represent single allelic variants or are they heterogeneous assemblages of variants with common electrophoretic mobility? Second, does the PGI locus itself respond to environmental selection or is the observed pattern of variation the result of selection at a closely linked locus? If PGI^{100} and PGI^{65} represent classes of alleles with common mobility, then parallel variation may imply greater functional similarity of allozymes within a single mobility class than between classes. On the other hand, if PGI^{100} and PGI^{65} each represent a single allele, then linkage alone can explain the parallel variation if recombination frequencies between the PGI locus and the locus under selection are very small (because disequilibrium must have persisted in both species since their divergence). Answers to these questions must await detailed structural and functional characterisation of individual electromorphs.

This work was supported by grants from the Theodore Roosevelt Memorial Fund of the American Museum of Natural History and the E. I. DuPont de Nemours Co., as well as by NSF grants to Peter F. Brussard, in whose laboratory this work was done. P. F. Brussard, S. A. Levin, R. J. MacIntyre and a reviewer made helpful comments on the manuscript.

Possible role for acetylcholine in aggregation centre spacing in *Polysphondylium violaceum*

WHILE ridding my laboratory of an invasion of flies, I tested the toxicity of an organophosphate insecticide, 2,2-dichlorovinyldimethylphosphate (DDVP), against the growth and development of *Polysphondylium violaceum* strain PvD 7206. Plate cultures of the slime mould exposed to the vapours of a pest strip containing the insecticide seemed to grow and develop normally in most respects, but showed a startling increase in the number of aggregation centres and sorocarps formed. I report here the results of preliminary investigations on the basis for this phenomenon.

A major biochemical effect of the organophosphates is inhibition of cholinesterase and/or other serine-esterases by phosphorylation of serine at the active site. DDVP seems to be a direct inhibitor, acting without prior metabolic conversion by the organism[2]. The effect of exposure to the pesticide strip could be most nearly duplicated by exposing postvegetative cells deposited on membrane filters to filter pads saturated with a solution of 3×10^{-1} M DDVP (Fig. 1*a*, *b*). Concentrations below 1×10^{-4} M were not effective; concentrations above 5×10^{-3} M inhibited aggregation. It should be noted that the exposure conditions are not precisely equivalent. Cells exposed to the pesticide strip are under continuous assault from the vapours, whereas DDVP on filters is at maximum concentration only at the beginning of the exposure period. The compound is volatile and may evaporate from the filter surface. It is also subject to attack by phosphatases[2] and may be actively degraded by the slime mould.

The choice of PvD 7206 (ref. 1) for the initial assay of the DDVP effect proved to be fortunate. In dense plate cultures this strain aggregates with some reluctance; confluent cultures form extensive tortuous streams, but may produce only a few decisive centres and large branched sorocarps. Exposure to DDVP vapours increases the number of centres produced in these conditions nearly 100-fold. Other stocks of *P. violaceum*, for example, PvD 7209 (ref. 1), normally aggregate avidly, producing hundreds of sorocarps, and the effect of DDVP is less spectacular. In populations of postvegetative amoebae allowed to develop on filters, there is little difference in the response of the two strains to DDVP; the number of centres is increased 2- to 4-fold in either case. The low frequency of centre emergence seen in confluent cultures of PvD 7206 may indicate that this strain is unusually sensitive to the centre-

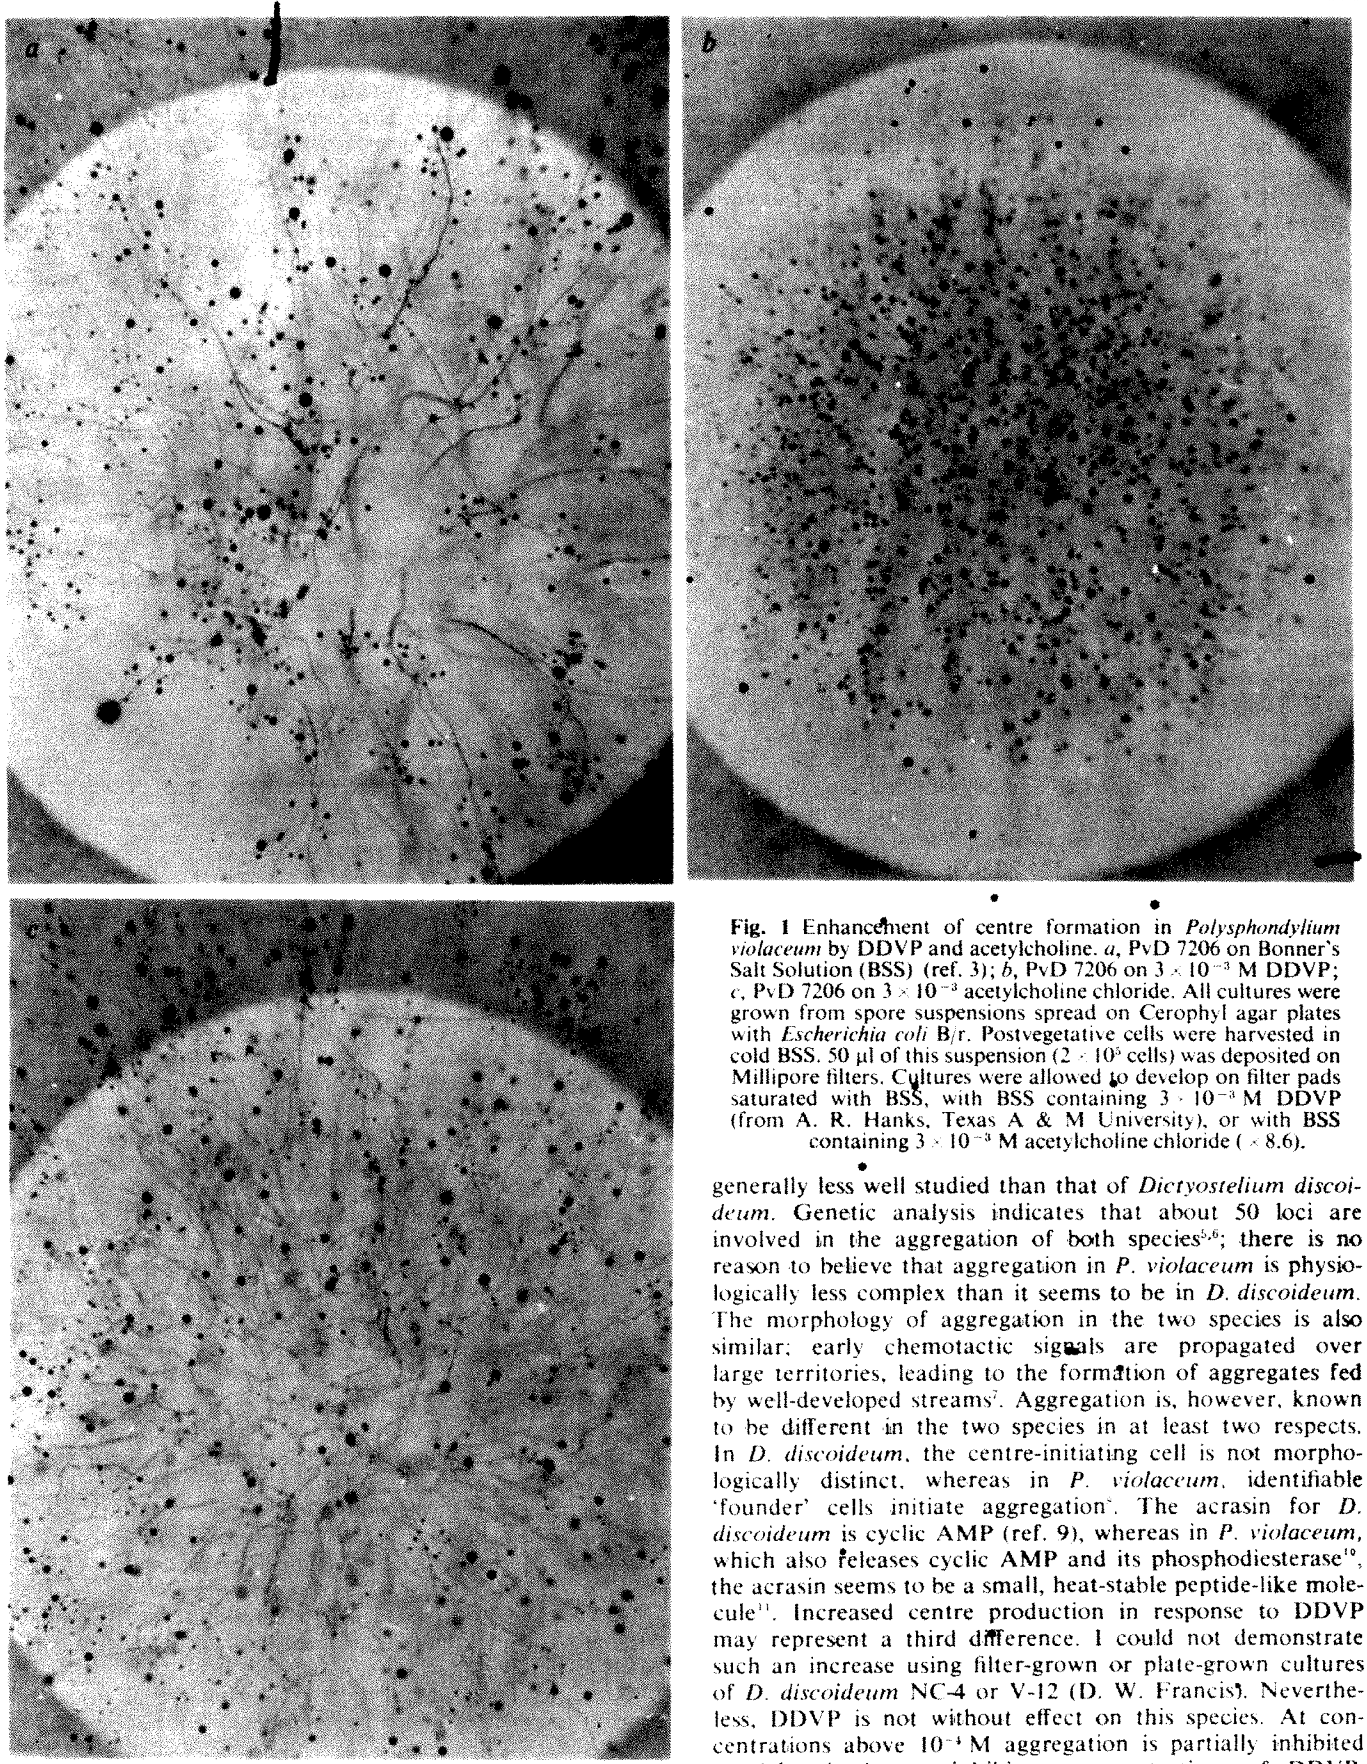

Fig. 1 Enhancement of centre formation in *Polysphondylium violaceum* by DDVP and acetylcholine. *a*, PvD 7206 on Bonner's Salt Solution (BSS) (ref. 3); *b*, PvD 7206 on 3×10^{-3} M DDVP; *c*, PvD 7206 on 3×10^{-3} acetylcholine chloride. All cultures were grown from spore suspensions spread on Cerophyl agar plates with *Escherichia coli* B/r. Postvegetative cells were harvested in cold BSS. 50 μl of this suspension (2×10^5 cells) was deposited on Millipore filters. Cultures were allowed to develop on filter pads saturated with BSS, with BSS containing 3×10^{-3} M DDVP (from A. R. Hanks, Texas A & M University), or with BSS containing 3×10^{-3} M acetylcholine chloride (× 8.6).

inhibiting mechanism involved in spacing in this species. Inhibition of centre formation by a diffusible substance emanating from previously established centres has been demonstrated in *P. violaceum*[4], but the inhibitor has not been identified.

The physiology of aggregation in *P. violaceum* is generally less well studied than that of *Dictyostelium discoideum*. Genetic analysis indicates that about 50 loci are involved in the aggregation of both species[5,6]; there is no reason to believe that aggregation in *P. violaceum* is physiologically less complex than it seems to be in *D. discoideum*. The morphology of aggregation in the two species is also similar; early chemotactic signals are propagated over large territories, leading to the formation of aggregates fed by well-developed streams[7]. Aggregation is, however, known to be different in the two species in at least two respects. In *D. discoideum*, the centre-initiating cell is not morphologically distinct, whereas in *P. violaceum*, identifiable 'founder' cells initiate aggregation[8]. The acrasin for *D. discoideum* is cyclic AMP (ref. 9), whereas in *P. violaceum*, which also releases cyclic AMP and its phosphodiesterase[10], the acrasin seems to be a small, heat-stable peptide-like molecule[11]. Increased centre production in response to DDVP may represent a third difference. I could not demonstrate such an increase using filter-grown or plate-grown cultures of *D. discoideum* NC-4 or V-12 (D. W. Francis). Nevertheless, DDVP is not without effect on this species. At concentrations above 10^{-4} M aggregation is partially inhibited or delayed. At non-inhibitory concentrations of DDVP, centre and slug formation seem normal, but at culmination the slug tip regresses, the sorogens become club-shaped and may arrest without further differentiation or produce sorocarps with relatively short stalks. Slug migration is also suppressed. Hanks (personal communication) has noted that another organophosphate, malathion, both accelerates aggregation and increases the number of centres formed in submerged populations of *D. discoideum* Ax-2. Whether this represents a response similar to that of *P. violaceum* to DDVP has not been established. It may be a unique consequence of the use of malathion, the difference in assay conditions, or the use of Ax-2; other idiosyncratic responses of the axenic strains have been noted[12]. Some organophosphates may, by acting as phosphate donors competitive with ATP, intervene in the membrane phosphorylation that precedes and has been reported to accelerate aggregation in *D. discoideum* (ref. 13).

The increased centre production by *P. violaceum* in the presence of DDVP suggests that cholinesterase or another serine-esterase is instrumental in determining the size of the aggregation territory in this species. The possible existence of a cholinergic communication system in this cellular slime mould is appealing in view of the role of acetylcholine in synaptic transmission, and the suggestion of McMahon[14] that neurotransmitters may function as developmental regulators. Preliminary evidence that the DDVP effect is at least in part a consequence of interference with a cholinergic mechanism is summarised in Table 1. Organophosphate inhibition of cholinesterase might be expected to facilitate an increase in the concentration of acetylcholine. Postvegetative cells of *P. violaceum* 7206 exposed to exogenous acetylcholine (3×10^{-3} M) showed an increase in centre production similar to that seen with DDVP. Culmination of these centres may, however, be incomplete, as the number of sorocarps produced seems to be intermediate (Fig. 1*c*); acetylcholine-treated populations produce more sorocarps than control populations, but fewer sorocarps than DDVP-treated populations. Atropine, an acetylcholine antagonist, reduces or inhibits centre formation. Eserine, a known inhibitor of cholinesterase, also stimulates centre formation, although its effect is less striking than that of DDVP. The difference may reside in their mode of action; eserine binds reversibly to cholinesterase, while the dimethyl phosphate of DDVP is covalently attached to the enzyme[2]. DDVP may also have effects other than those related to cholinesterase inhibition. These observations suggest that acetylcholine reduces territory size in *P. violaceum* and that cholinesterase increases it. Further speculation about the mechanism of this activity and its relationship to cyclic nucleotide metabolism and the ionic fluxes of aggregation should be reserved until the elements of a cholinergic system are isolated and unequivocally identified. *P. violaceum* synthesises several DDVP-sensitive enzymes with esterase activity (Clark, McCoy, and Whitmore, unpublished observations); an effort to associate one or more of these enzymes with the centre-increasing effect of DDVP, and to identify a cholinesterase among them, has been initiated.

Table 1 Effect of various additives on centre production of *P. violaceum*

Additive	Relative no. of centres formed
BSS	1.0
DDVP	
3×10^{-3} M	4.0
1×10^{-3} M	2.5
Acetylcholine	
3×10^{-3} M	3.5
1×10^{-3} M	1.1
Atropine	
3×10^{-3} M	0
1×10^{-3} M	0.6
Eserine	
1×10^{-3} M	2.6
1×10^{-4} M	1.6

Filter cultures were prepared as indicated in Fig. 1, except that some experiments were done using drop sizes at 10 or 20 µl for easier centre counting. Number of centres was determined by counting the average number of centres formed on three filters. Data from several independent experiments were combined for comparison by setting all figures relative to an arbitrary control (BSS) value of 1.0. The number of centres produced by control cultures averaged 17 for 10-µl drops and 90 for 50-µl drops. Variation for any set of testing conditions was 20% or less.

I thank the University of Texas at Arlington for funding, Drs Howard Arnott and Wayne Fagerberg for the use of their photographic equipment and advice, Ms Lonna Withers for technical assistance and Mrs Nancy Banks for secretarial help.

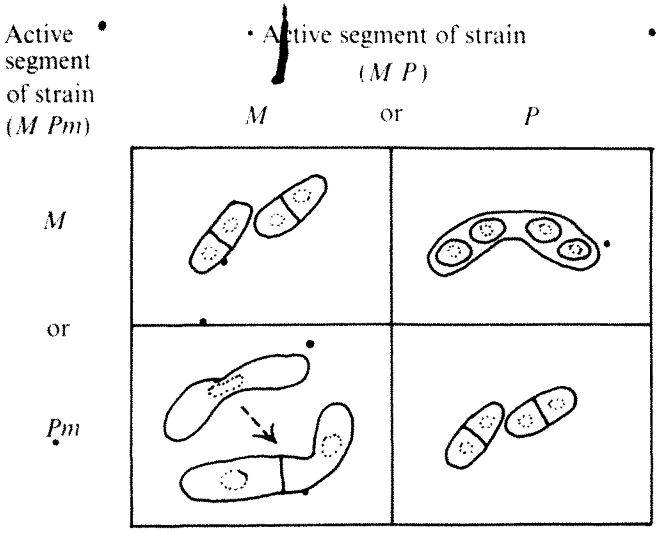
Frequency of mating-type switching in homothallic fission yeast

THE genes determining mating type in the fission yeast *Schizosaccharomyces pombe* are of particular interest in the general study of the genetic control of differentiation. The genetic segments concerned, *mat1*^{M} and *mat2*^{P}, specifying mating type (−) and (+), respectively[1], are present, closely linked, in homothallic strains[2], but on any one chromatid (that is in the *cis* position) they are only expressed in a mutually exclusive manner[3]. The segments of the mating-type locus, *mat1*^{M} and *mat2*^{P}, govern the transition from vegetative growth to sexual reproduction. They act in a complementary fashion—one functional *M* segment and one functional *P* segment are always required to initiate both conjugation (usually among haploid cells) and meiosis (leading to sporulation in either zygotes or diploid cells), the prominent events in differentiation in *S. pombe*. A mating-type mutant defective in meiosis but not in conjugation (*mat1*^{M} *mat2*^{Pm}) when crossed with wild type, produces sporulating and non-sporulating zygotes (Fig. 1). These two classes indicate that in individual cells of either parent strain only one or the other mating-type segment is active[3]. Here I describe a single-cell evaluation of this cross, and show (also by single-cell techniques) that the frequency of mating-type switching in haploid and diploid strains is approximately random. A favoured mechanism for this type of switching is the inversion of a promoter element between the structural genes, the direction of the promoter determining which mating-type segment is switched on.

Cells of *S. pombe* are usually haploid during vegetative growth. It is only when the culture medium becomes exhausted, particularly of nitrogen, that diploid zygotes are formed by pairwise cell fusion. If left undisturbed, these zygotes undergo meiosis and sporulation, thereby immediately regenerating the haploid state. Yet it is possible to induce diploid division in a small fraction of wild-type zygotes or very efficiently in certain mutants[4]. When Leupold introduced *S. pombe* into basic genetics (see ref. 2), his strain already consisted of a mixture of heterothallic clones, in which either mating type ((+) or (−)) is heritably stable or nearly so, and of homothallic ones, in which conjugation is possible even among sister cells. Heritable changes of mating type occur in various directions[1-3], usually of the order of 10^{-4} per cell division;



Active segment of strain (M Pm)
Active segment of strain (M P)
M
or
P
M
or
Pm

Fig. 1 Zygote classes of cross (*M Pm*) × (*M P*). On the assumption that cells of either parent strain can only activate one *mat* segment or the other, the possible four pair-wise combinations are indicated by this scheme. Two cells expressing the same mating type do not interact and, at best, divide again mitotically. Two cells expressing opposite mating types can either sporulate, if the (+) cell is wild type, or not, if the (+) cell is mutant for the *Pm* allele. Since the genetic block of this mutation is effective before commitment to meiosis[4] and before premeiotic DNA replication[10], most zygotes of the latter class can be induced to resume diploid division by a transfer to growth medium.

this is more frequent than ordinary mutations, though well below the rapid switching reported here.

In the cross of (*M Pm*) × (*M P*), illustrated in Fig. 1, both parent strains are homothallic and can produce zygotes by selfing, in addition to the really informative zygotes of hybrid descent. Colonies originating from the various classes of zygote can be distinguished by the expression of marker genes (two *ade6* alleles in this cross) (Table 1). Evidently selfing (I, II) was still preferred over crossing (III, IV); but the hybrid colonies (III compared with IV) are compatible with a 1:1 distribution with regard to the two classes of zygote indicated in Fig. 1. A few non-sporulating zygotes in fact give rise to segregating haploid colonies rather than to diploid ones, leading to incidental misclassification. Some additional uncertainty is introduced by the unclassified number of zygotes (V) that failed to form colonies. The colonies produced by class III zygotes contain sporulating and non-sporulating diploid cells. This aspect is discussed below.

The next point of interest is the frequency with which cells can alternate their choice as to which mating-type segment is to be expressed. Unfortunately, clear-cut tests for both (+) and (−) mating-type activities of single cells, such as have been worked out for budding yeast[5], are not yet feasible in *S. pombe*.

Table 1 Colonies from zygotes of cross (*M Pm*) *ade6-M216* × (*M P*) *ade6-M210*

	Colour	Colonies	Interpretation
I	Light red	109	diploid, homozygous for *M216*; selfing of (*M Pm*)
II	Dark red	68	haploid, *M210*; selfing of (*M P*)
III	White	28	diploid, heterozygous *M-216*/*M210*; cross, diploidised zygotes
IV	Streak-sectored, light/dark red	37	haploid, *M216* and *M210*; cross, sporulated zygotes
V	Zygotes that failed to grow	76	?

Cells of the strains (*M Pm*) *ade6-M216* and (*M P*) *ade6-M210* were crossed by the shift method[10] (transfer to liquid medium devoid of a nitrogen source). After agglutination had just started, the culture was briefly sonicated to reduce the chance of selfing in either parent strain. Two hours later, samples were streaked on agar slabs, and individual zygotes were isolated by micromanipulation. The slabs were then transferred to YEA plates (yeast extract agar, unsupplemented with adenine) and incubated for colony production. On this medium, both *ade6* alleles used in this cross can be distinguished by different intensities of a pink pigment. No pigment is formed in heterozygous diploid colonies, owing to allelic complementation[11].

In the experiment considered here, a haploid, homothallic strain has been used that is wild type at its mating-type locus (*M P*) but mutant at two other genes, *fus1* and *cdc2*. Conjugation is initiated as usual, but cell fusion is prevented by the *fus1* mutation[4]. The *cdc2* marker is a temperature-sensitive cell cycle mutation blocked in nuclear division[6].

The rationale was as follows. Haploid cells affected by *fus1* could at best form 'prezygotes', pairs of cells recognisable by their attached conjugation tubes. The asci observed after high-temperature exposure could only have arisen by endo-diploidisation (provoked by *cdc2*). The sister chromatids emerging from the previous replication are distributed to sister cells if division is possible, or remain within the same cell after endo-diploidisation. Since different mating-type segments must be activated on sister chromatids in order to produce a pair of prezygotic cells after one division, or a single ascus without division, these events are suitable indicators of mating-type switching.

Results are given in Table 2. If the frequency of switching were high enough for one mating-type segment or the other to be activated at random on any one chromatid, just half the uninucleate cells plated to sporulation medium should develop to a single ascus or a pair of prezygotic cells. The observed frequencies reach about half this expectation, and may actually be closer to randomness if the efficiency of conjugation induction or of endo-diploidisation is less than 100%.

Table 2 Oppositely activated mating-type segments on sister chromatids of strain (*M P*) *cdc2 fus1*

	Hours at 36 °C		
	0–2.5	3.5–5	20
Total	451	184	56
1n	322	131	40
2pz	68	(5)	—
1a	(1)	34	—
Fraction	2pz/1n =0.21	1a/1n =0.26	

1n, uninucleated cells at plating, as calculated from the fraction of single cells in the last column;

2pz, one pair of prezygotic cells produced by the first division;

1a, single ascus, produced without division.

Haploid cells of the strain (*M P*) *fus1 cdc2* were cultured in liquid sporulation medium supplemented by a nitrogen source[5]. Cells were then plated on agar medium of the same composition but lacking the nitrogen source. Only one or two residual divisions are usually observed on this medium before induction of conjugation and/or meiosis. The plates were incubated at 36 °C for different lengths of time and shifted back to 30 °C. About 20 h after plating, all plates were inspected microscopically, and the different combinations of prezygotic cells, asci, or neutral cells that had been formed after one or two residual divisions were counted. The most informative configurations (2pz and 1a) are represented here. One plate (last column) was incubated at 36 °C throughout to calculate the fraction of plated cells that had been arrested without division at the non-permissive temperature (corresponding to the uninuclear fraction at the time of plating).

The third experiment was designed to estimate frequencies of switching in diploid cells heterozygous for (*M Pm*)/(*M P*), which had been derived from the first cross (Table 1, class III). This test was performed as a pedigree analysis of cells on a growth-limiting and sporulation-inducing medium. In principle, each newly separated cell had three choices as depicted in Fig. 2. The rationale was that the different combinations of activated *mat* segments, which are indicated for separate haploid cells by Fig. 1, are now carried by individual diploid cells. A cell could develop into an ascus, provided that mating-type segments were properly activated in the wild-type combination, or develop the 'premeiotic' phenotype peculiar to the *Pm* mutation; or else it could divide again mitotically. The first two possibilities represent the alternative choices of complementary mating-type activation. The pattern by which these configurations are distributed through the

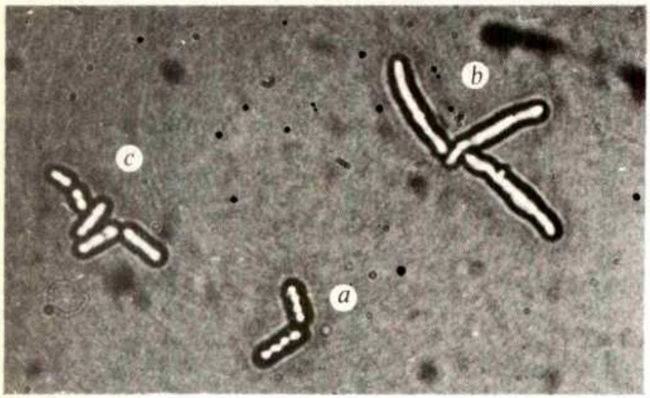


Fig. 2 Three choices of heterozygous (*M Pm*)/(*M P*) cells. Diploid cells of a heterozygous (*M Pm*)/(*M P*) strain were plated to sporulation medium, and observed after being incubated overnight. The progenies of three individual cells are depicted in this illustrative, though highly selected view, in which descendants of any one cell happened to be identical. *a*, Two asci have developed after one division; *b*, three 'premeiotic' cells have resulted from two divisions; *c*, five still vegetative-looking cells have been formed by four divisions. These possibilities were used to infer the states of activation for the different *mat* alleles during pedigree analysis. The 'premeiotic' phenotype, attributable to the *Pm* mutation, is equivalent to the aberrant elongation generally observed when DNA replication is selectively inhibited.

pedigrees should reveal for how many divisions a given combination is propagated, or how frequently the cells can switch.

Data of this analysis are given in Table 3. In *a*, single cells are evaluated with respect to the three choices listed above. The observed distribution is somewhat skewed in favour of dividing cells and premeiotic cells. In *b*, cell pairs (sister cells) are evaluated, and compared with the expectation based on a random choice after each division and biased by the skewed distribution seen in *a*. Evidently, even pairs (cc, pp, aa) are favoured over odd pairs (pc, ac, pa). Hence, a low degree of heritability has to be assumed for the different combinations of activated *mat* segments. On the other hand, the 'pa' pairs (an ascus formed next to a premeiotic cell) deviate relatively little from the expected value.

A random-choice distribution corresponds to an average frequency of 0.5 switches per chromatid and division. If the actual frequency were half that value, the expected value for a double event (changes on both chromatids), such as the formation of a 'pa' pair, should have dropped to a quarter: from 75 to 19. This value is considerably lower than the observed 58 pairs of this kind.

Randomness as to which *mat* segment is activated on any one chromatid is therefore fairly well approximated in both haploid and diploid cells of homothallic *S. pombe* strains. The *cis*-acting functional exclusion of either mating-type segment by the other can best be explained by intra-strand recombinational models that allow for rearrangements of structural genes relative to their controlling signals. Since, in *S. pombe* at least, the respective silent segment of the mating-type locus is still located at its original position on the chromosomal map, a flip-flop model by means of an invertible promoter element between the structural genes of the $mat1^{M}$ and $mat2^{P}$ segments is favoured for this yeast[7]: the relative direction of the promoter element then determines the mating-type segment to be activated in conditions for conjugation. Such a scheme has the advantage that a variety of genetic instabilities, all localised at the mating-type locus[1-3], can be attributed to a common mechanism of site-specific recombination. There are, of course, other explanations for a random-choice mechanism, but mutants have been described[8] that seem to reduce the rates of switching, so that sizeable clones of one mating type or the other are produced, which can best be explained by reversible alterations at the level of the gene.

Table 3 Pedigrees of diploid (*M Pm*)/(*M P*) cells

a	c	p	a	Total		za
Observed	1322	488	328	2138		(32)
Fraction	0.62	0.23	0.15			
b, pairs	cc	pp	aa	pc	ac	pa
Observed	494	136	47	158	176	58
Expected	408	56	25	302	203	75

c, Cell divided again.
p, Premeiotic cell.
a, 'Azygotic' ascus (sporulated cell with haploid spores).
za, 'Zygotic' ascus (sporulated zygote with diploid spores).

Diploid (*M Pm*)/(*M P*) cells were cultured and streaked to agar slabs as indicated below Table 2. Contrary to the previous experiment, however, more than two residual divisions were possible this time, owing to some impurities in a new batch of agar. Pedigrees were started by isolating cells that had just divided. For several generations, sister cells were separated by micromanipulation. The slabs were then incubated overnight and evaluated microscopically. Since conspicuous clustering of any sort was not noticed in these pedigrees, only pairs of sister cells are considered here, and the data are pooled for the first four rounds of cell division. Occasionally, 'zygotic' asci had been formed by inseparable sister cells; but these have not been considered further, since their interpretation is ambiguous.

The independent control of mating-type switching on both chromosomes of diploid *Schizosaccharomyces* cells is at variance with homothallism in *Saccharomyces*, where switching ceases after conjugation, and the resulting diploid cells stably transmit a once assumed *a*/α configuration[9] (*a* and α are the mating types of that yeast). This discrepancy seems to be related to the different life cycles of both yeasts. Most budding yeasts have evolved to a stable diploid growth phase by means of conjugating under growth conditions and zygotic budding, whereas fission yeasts do not usually grow as diploids, since conjugation is confined to starvation and is followed by zygotic reduction and sporulation. Whereas the latter condition does not require a special stabilisation for the diploid state, continued mating-type switching is incompatible with the life cycle of a budding yeast, since it would inevitably lead to excessive polyploidisation.

Rapid, chloramphenicol-resistant, activation of membrane electron transport on germination of *Bacillus* spores

KEILIN[1] observed that the life cycle of diverse organisms includes a stage when life seems to be arrested, which he termed the cryptobiotic state. As an example of this, the mature bacterial spore can remain dormant with no detectable metabolism for long periods and then on exposure to germinants, rapidly germinate and outgrow in a synchronous manner, to yield a vegetative cell. We have been particularly interested in the composition and activities of the membrane-bound electron transport chain in sporulating *Bacillus megaterium* KM (ref. 2) and in the unique reversed orientation which characterises the membranes surrounding the developing spore[3]. This report describes the rapid changes observed in the membrane of *Bacillus megaterium* KM spores during germination and outgrowth. A rapid chloramphenicol-resistant, activation of membrane NADH oxidase activity occurred within 5–10 min of germination. Membrane-bound DL-α-glycerol-P and L-malate oxidase activities appeared sequentially at later times and their appearance was prevented by

Table 1 Development of inner membrane oxidase activities during spore germination and outgrowth

The sporulation medium (CCY medium) used to produce spores was a modification of that used previously[14 15] This contained $MgCl_2$ $6H_2O$ (0 5 mM), $MnCl_2$ $4H_2O$ (0 01 mM), $FeCl_3$ $6H_2O$ (0 05 mM), $ZnCl_2$ (0 05 mM), $CaCl_2$ $6H_2O$ (0 2 mM), KH_2PO_4 (30 mM), K_2HPO_4 (10 mM), glutamine (20 mg l^{-1}), acid casein hydrolysate (1 g l^{-1}), enzymatic casein hydrolysate (1 g l^{-1}), enzymatic yeast extract (0 4 g l^{-1}) and glycerol (0 6 g l^{-1}) Mature spores liberated on completion of sporulation in this medium were collected by centrifugation and repeatedly washed in deionised water (4 °C) Spore suspensions (50 mg dry weight ml^{-1}) were heat-activated in deionised H_2O at 70 °C for 30 min, allowed to cool to room temperature then resuspended in modified CCY medium plus germinants (1 mM L-alanine + 5 mM inosine) to a density of about 0 5 mg dry weight ml^{-1} The suspensions were incubated at 30 °C on an orbital shaker (220 r p m) for various times before being chilled by addition of ice cubes followed by rapid centrifugation at 4 °C The organisms were resuspended in 0 05 M Tris-HCl, *p*H 7 5 (4 °C), mixed with cooled glass beads and broken in the Braun cell disruptor for 1 min with liquid CO_2 cooling Spore integuments and occasionally a few unbroken organisms were removed by centrifuging (25,000*g* for 3 min at 4 °C) and the resulting supernatant was centrifuged at 105,000*g* for 1 h at 4 °C to deposit the membrane fraction The membrane fraction was washed once by resuspension in 0 05 M Tris-HCl (4 °C) containing 5 mM $MgCl_2$ Oxidase activities at 30 °C were determined as described previously[2] *a* and *b* refer to separate experiments

chloramphenicol Evidence is presented to suggest that in the dormant spore the electron transport sequence is blocked in the region between NADH dehydrogenase and the cytochromes

Table 1 shows that both dormant and heat-activated spore membranes had essentially the same low NADH oxidase activity. Within 5–10 min of germination there was a 5–10-fold stimulation of NADH oxidase activity (Tables 1 and 2) that probably increased further during the germination and outgrowth sequence. L-malate oxidase activity was first detectable after 50 min and had not reached full vegetative cell membrane levels of activity (approximately 50 nmol O_2 min^{-1} mg^{-1}) after 100 min DL-α-glycerol phosphate oxidase activity was detectable after 10 min and attained approximately vegetative cell membrane levels of activity (70 nmol O_2 min^{-1} mg^{-1}) during the experimental period DL-α-glycerol-P dehydrogenase activity showed a similar pattern (Table 2)

It was of interest to see whether these changes in oxidase activities were the result of protein synthesis or activation of pre-existing proteins Steinberg *et al.*[4] had reported a rapid, chloramphenicol insensitive increase in oxygen uptake in the first minutes of *B. cereus* spore germination .In an experiment where the dormant spore membranes had an NADH oxidase activity of 67 nmol O_2 min^{-1} mg^{-1} protein, the membranes of organisms germinated for 10 min in the presence or absence of chloramphenicol (100 μg ml^{-1}) had activities of 723 and 855 nmol O_2 min^{-1} mg^{-1} protein, respectively This level of chloramphenicol completely inhibits protein synthesis during germination of *B. megaterium* spores[5]. When spores were germinated with chloramphenicol for longer periods (Table 2), DL-α-glycerol P and L-malate oxidase activities did not appear, indicating a requirement for protein synthesis for incorporation of these activities into the membrane. Once again, the initial rapid increase in NADH oxidase activity was unaffected by chloramphenicol but the activity subsequently decreased after 20 min (see Table 2), indicating new protein synthesis to be necessary to maintain this level of activity later in the germination sequence

To determine whether the NADH oxidase activation occurred generally over the whole electron transport sequence, or whether a specific portion was stimulated, certain segments of the sequence were assayed using artificial electron donors and acceptors (Table 2) These experiments revealed that heat activation had no significant effect on the activity of any of the enzymes in Table 2, NADH–DCPIP reductase activity was higher than NADH oxidase activity and did not change significantly on germination, NADH–cytochrome *c* reductase activity showed a dramatic increase on germination, of the same order as the increase in NADH oxidase; and that ascorbate–TMPD oxidase activity was low and did not increase on germination. These results suggest that the electron transport sequence of the dormant spore membrane is blocked between the dehydrogenase and cytochrome *b* regions.

Room temperature reduced minus oxidised difference spectra did not reveal any rapid change in membrane cytochrome co[illegible] during germination. NADH reduced aerobic minus oxidised, liquid nitrogen temperature spectra revealed a lower steady state level of reduction of the cytochromes in the dormant spore membranes than in membranes from spores germinated for 10 min, which together with the assays of the segments of the electron transport sequence, is consistent with a block located in the sequence before the cytochromes

When spores were germinated in phosphate buffer plus germinants immediately after heat activation (Fig. 1), oxygen uptake measured in the oxygen electrode was first detectable after about 2 min The rate of uptake then increased rapidly, so that by 7 min the suspension was respiring vigorously (25 8 nmol O_2 min^{-1} mg^{-1} dry weight of spores). This oxygen uptake did not occur in the absence of germinants and was unaffected by chloramphenicol. The results were the same for spores germinated in the more complex modified CCY medium (Fig. 1). Inclusion of KF (10 mM) in the germination medium slightly delayed the onset of rapid respiration but the final rate attained was little different from that of control suspensions, as described previously[6] With KCN (10 mM) present, the maximum rate of respiration was approximately half that of the controls The rapid rate of respiration attained within the first 7 min of germination corresponds to that

Table 2 Assays of segments of the electron transport chain during germination

The experimental details were essentially as in Table 1 Enzyme assays were carried out at 30 °C as described previously[2 3] Assays of ascorbate–TMPD oxidase contained 10 mM ascorbate and 0 1 mM TMPD Correction was made for the low non-enzymatic oxidation of ascorbate–TMPD *a* and *b* refer to separate experiments, in *c*, the germination was carried out in the presence of chloramphenicol (100 μg ml^{-1}) Enzyme activities are expressed in the following units NADH oxidase (nmol O_2 min^{-1} mg^{-1} protein); NADH–2,6-dichlorophenol-indophenol reductase (μmol 2,6-dichlorophenol-indophenol reduced min^{-1} mg^{-1} protein), NADH–cytochrome *c* reductase (nmol cytochrome *c* reduced min^{-1} mg^{-1} protein) Ascorbate–TMPD oxidase (nmol O_2 min^{-1} mg^{-1} protein), DL-α-glycerol-P oxidase (nmol O_2 min^{-1} mg^{-1} protein), DL-α-glycerol-P–2,6-dichlorophenol-indophenol reductase (μmol 2,6 dichlorophenol-indophenol reduced min^{-1} mg^{-1} protein)

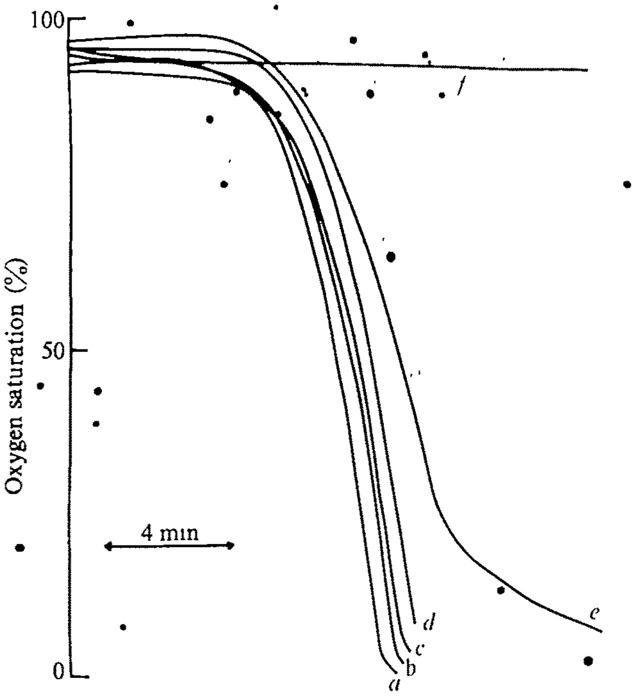

Fig 1 Aliquots of washed concentrated spores in deionised water (10 mg dry weight ml^{-1}) were heat activated by heating in a water bath at 70 °C for 30 min Immediately after heat activation, 0 2 ml of this spore suspension was added to the reaction vessel of the oxygen electrode Incubations were as follows 50 mM KH_2PO_4/K_2HPO_4 (pH 7.5) containing 1 mM L-alanine and 5 mM inosine (*b*), *c*, *d* and *e* repeats of (*b*) with addition of 100 μg ml^{-1} chloramphenicol, 10 mM potassium fluoride and 10 mM potassium cyanide, respectively, *f*, result of incubation in 50 mM KH_2PO_4/K_2HPO_4 (pH 7 5) alone. The final incubation volume was 3 ml in all cases and the reaction vessel temperature was maintained at 30 °C

observed by Steinberg *et al*[4] and correlates with the observed increase in membrane NADH oxidase activity.

This rapid chloramphenicol-insensitive activation of the respiratory membrane of the spore on germination seems to be a general property of *Bacillus* spores, since similar results to those described here have been obtained for all species so far examined including *B. cereus* and *B subtilis* The activation also occurs in the absence of membrane lipid synthesis which is not detectable until 10 min after germination[7]. When spores were germinated in 40 mM Tris-HCl buffer containing either 1 mM L-alanine or 40 mM calcium-dipicolinic acid[8], the same pattern of NADH oxidase activation was observed. Since, in these conditions the spores could germinate but not outgrow, it would seem that the activation is not inextricably linked to spore outgrowth.

The biochemical basis of the suggested block in the dormant spore electron transport chain now remains to be determined Possible mechanisms to account for its rapid removal during germination include degradation or dissociation of an inhibitor and membrane conformational changes resulting from the expansion of spore membrane which is thought to occur early in germination. Although lipid synthesis is not detectable until 10 min after germination is initiated, turnover of existing spore membrane lipids starts almost immediately on initiation and is therefore occurring the period of NADH oxidase activation[7].

Rapid increases in respiratory rates upon termination of the cryptobiotic stage have also been recorded for fungal spores[9], and insects in diapause[10]. To what extent activation of pre-existing enzymes is involved in these instances is not known. Activation dose seem to have a role in sea urchin eggs after fertilisation, where the sudden increase in respiratory activity was found to be insensitive to chloramphenicol and actinomycin D (refs 11 and 12). In etiolated primary leaves of *Phaseolus vulgaris*, green chloroplasts formed during exposure to short light flashes did not exhibit Photosystem II activity. These chloroplasts, however, acquired the full Photosystem II activity within minutes after exposure to continuous light, suggesting that some form of activation is occurring[13] It is not known whether this activation is independent of protein synthesis

Solubilisation of atropine-binding material from brain

MUSCARINIC receptors have been characterised extensively in intact smooth muscle[1–3] and in subcellular fractions from smooth muscle[2,4–6] and brain[7–10] by reversible binding of labelled atropine[1,8,10], propylbenzilylcholine[9,10], quinuclidinylbenzilate (QNB) (refs 6, 8) and benzetimide[4,5], or by alkylation with benzilylcholine[2] or propylbenzilylcholine mustard[3,7,9–11]. Several attempts to solubilise muscarinic receptors[2,4,12] have failed due to the inhibition of receptor binding by the detergent used for solubilisation[2,4]. We report here the solubilisation with 2M sodium chloride of an atropine-binding material from the ox cerebral cortex, which has properties similar to those found for the muscarinic receptor in subcellular preparations.

Figure 1*a* shows the binding of (±) ^{3}H-atropine to a crude synaptosomal preparation isolated from the cerebral cortex; the measured dissociation constant (K_D) was 2.0±0.3 nM, the Hill coefficient n_H was 1.0 and the concentration of the binding sites was 2.0±0.5 nmol g^{-1} protein. The high affinity binding of labelled atropine could be displaced by unlabelled atropine, scopolamine, lachesine and QNB. The estimates of the inhibition constants (K_i) of these antagonists, together with those of agonists (determined in this study and by other groups) are shown in Table 1 There was close agreement between the constants measured in our preparations and those reported by others although, in our hands, QNB showed two distinct affinities ($K_i = 2\times10^{-10}$ M and 3×10^{-8} M) of which only the higher affinity value has been reported before[8], possibly because its binding had not been studied at sufficiently high concentrations.

Figure 2 illustrates the inhibition by acetylcholine of binding of labelled atropine to the membrane preparations. The inhibition curve indicates two binding sites for acetylcholine: a high affinity site with $ID_{50} = 10^{-5}$ M and a lower affinity site with $ID_{50} = 10^{-3}$ M. These values correspond to values of K_i of 3×10^{-6} M and 3×10^{-4} M, respectively. Three other agonists, acetyl-β-methylcholine, oxotremorine and carbamylcholine gave similar biphasic curves for inhibition of atropine binding. Their affinity constants derived from the competition with ^{3}H-atropine were respectively 3×10^{-6} M and 10^{-4} M, 3×10^{-7} M and 2×10^{-5} M, and 2×10^{-6} M and 2×10^{-4} M We found that the high-affinity binding component represented 35–45% of the total number of atropine-binding sites, a figure similar to the 32% reported by Hulme *et al.*[9,10]. These two components of the curve could represent identical muscarinic binding sites under different membrane restraints, or alternatively, only the high affinity site may be related to the receptor. A single binding constant was found for pilocarpine and arecoline (10^{-6} M and 2×10^{-6} M, respectively) and choline was ineffective up to millimolar concentrations. The K_i values found for both agonists and antagonists agree reasonably well with those reported by Yamamura *et al.*[8] for subcellular brain preparations and with the agonist binding associated with smooth muscle contraction[1,13]. Drugs unrelated to the muscarinic system generally did not displace the binding of labelled atropine.

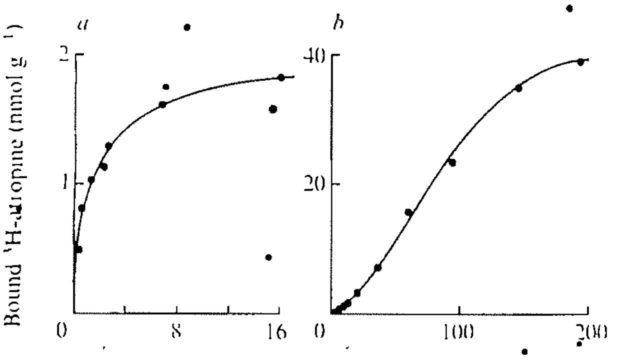

Fig. 1*a*, Binding of ^{3}H-atropine to a crude synaptosomal preparation from ox cerebral cortex The subcellular fraction was the P_2 pellet of Gray and Whittaker[14]. A sample (0.25 ml) of the P_2 suspension in 30 mM sodium phosphate buffer containing 100 mM sodium chloride, *p*H 7.4, at a protein concentration of 0.5–1.5 mg ml^{-1} was incubated at the room temperature for 10 min with ^{3}H-atropine with and without unlabelled atropine. A 200-µl sample was withdrawn and filtered on Millipore membranes and washed with 20 ml cold distilled water. Because the 'off' reaction of atropine from receptor is slow, the quantity of drug removed by this wash from the receptor should be very small. The filter was dried, then counted by liquid scintillation spectrometry in toluene–POPOP. The specific binding shown in the graph represents the difference in counts between uninhibited and inhibited (1 µM atropine) samples. $K_d = 2.0$ nM; $n_H = 1.0$. Apart from the binding site shown, two others were detected at higher concentrations of atropine, with $K_d = 4\times10^{-7}$ M and $K_d = 6\times10^{-6}$ M, their capacities being 20 and 180 nmol ^{3}H-atropine bound per g of protein respectively These two sites were not susceptible to muscarinic agents and thus unlikely to be related to the muscarinic receptor. (±) ^{3}H-atropine (170 mCi mmol^{-1}) was purchased from the Radio Chemical Centre, Amersham. *b*, Binding of ^{3}H-atropine to the solubilised receptor. The solubilised material was prepared as follows. Equal volumes of P_2 suspension (30 ml, at a protein concentration of about 10 mg ml^{-1}) and 4 M NaCl were mixed—giving a final NaCl concentration of 2 M—and the suspension was stirred vigorously for 2–3 h at 4 °C. It was then centrifuged at 15,000 r p.m. (28,000*g*) for 20 min, and the supernatant was diluted fourfold with 100 mM phosphate buffer *p*H 7.4 and recentrifuged at 25,000 r.p.m. (83,000*g*) for 2 h in the SW 27 rotor of a Beckman L5–40 ultracentrifuge To the resulting supernatant was added ammonium sulphate (55 g per 100 ml, over a period of 1 h during which the medium was stirred constantly) and the material was then centrifuged at 15,000 r.p.m. for 20 min to obtain the precipitated proteins. The combined pellets were dissolved in 5 ml 100 mM phosphate buffer *p*H 7.4, and dialysed exhaustively to remove ammonium sulphate. Finally, the dialysate was centrifuged at 15,000 r p.m. for 30 min and the supernatant (referred to as the solubilised material) was assayed for ^{3}H-atropine binding. About 5% of the total membrane proteins was solubilised. Proof that the material was soluble came from observations that no particulate matter was visible under the electron microscope and that the material did not sediment when centrifuged at 83,000*g* for 2 h. Binding of ^{3}H-atropine to the solubilised material was measured by rapid filtration on cellulose nitrate membranes (Selectron-Filter, type BA 85, 0.45 µm, Schleicher and Schull). Free ^{3}H-atropine was removed by washing the membranes with 20 ml cold distilled water. We could detect no binding if the solubilised material was heated for 10 min at 60 °C before binding assay. $K_{1/2} = 80$ nM; $n_H = 1.5$. From comparisons of atropine binding to the soluble material and to the P_2 fraction, before and after salt-treatment, we found that the number of solubilised binding sites was equal to 50±10% of the high-affinity P_2 sites (assuming quantitative absorption on to the cellulose nitrate membranes). Binding of ^{3}H-atropine to the solubilised material is being studied by equilibrium dialysis to determine the effectiveness of the cellulose nitrate membranes in retaining the soluble material ^{3}H-atropine binding to the solubilised material was unaltered after storage at 4 °C for 5 d.

After treatment of a crude synaptosomal preparation with 2M NaCl and separation of the solubilised material by centrifugation, binding of ^{3}H-atropine could be detected in the solubilised fraction by a filtration assay (Fig 1*b*). The binding curve was sigmoidal ($n_H = 1.5$), half-saturation ($K_{1/2}$) occurring at 80±30 nM, and the concentration of binding sites was 40±20 nmol g^{-1} protein.

The concentrations of unlabelled antagonists which reduce by 50% the level of specifically-bound ^{3}H-atropine (80 nM) (ID_{50} values) were found to be between 20 and 50 times higher than the corresponding concentrations found in synaptosomal preparations (Table 1). A single class of binding sites was found for each antagonist tested, the Hill coefficient being slightly greater than one (1.3–1.5) Competition by agonists of ^{3}H-atropine-binding was studied in the same way, as shown in Fig. 2 for acetylcholine. A single binding component was observed with $ID_{50} = 10^{-6}$ M: the Hill coefficient was 1.2. This competition was similar to the high affinity component observed for membrane preparations (Fig. 2). Oxotremorine, acetyl-β-methylcholine and carbamylcholine also displayed single binding constants (ID_{50} of 10^{-6} M, 10^{-5} M and 6×10^{-6} M, respectively).

The solubilised material thus contained a single, high affinity binding site for agonists with an ID_{50} value which closely parallelled that of the high-affinity component in the subcellular preparation. The low-affinity site was either lost, inactivated, left unsolubilised or converted to the higher affinity form. Antagonists bound to the soluble fraction with QNB being the most active, followed by scopolamine, atropine and lachesine—the same order as binding to the membrane fraction—but in a sigmoidal fashion and with lower affinities than to the membrane preparations. Such cooperativity may represent a transition of the soluble protein from a state of low to high affinity towards

Fig. 2 Inhibition of specific ^{3}H-atropine-binding to the P_2 fraction and to solubilised material by acetylcholine in the presence of 1 µM eserine sulphate The concentration of the ^{3}H-atropine was 4 nM for the P_2 fraction and 80 nM for the soluble fraction. Binding was measured as described in the legend to Fig. 1. ○, P_2 fraction, ●, P_2 fraction—high-affinity binding component; ×, solubilised material.

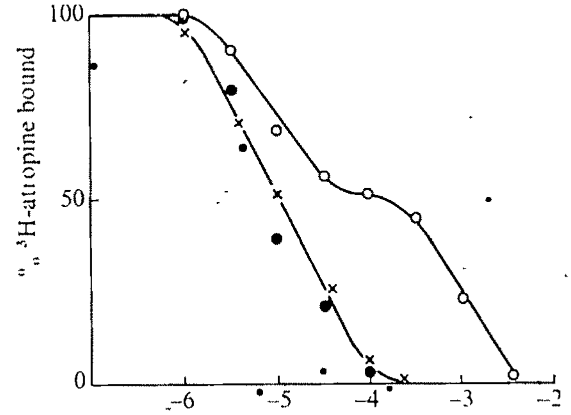

Table 1 Binding characteristics for membrane-bound and soluble atropine-binding material

Drugs	Particulate preparations Rat brain* ID_{50} (M)	Rat brain† ID_{50} or K_i (M)	Ox brain§ K_i (M)	Soluble material Ox brain§ ID_{50} (M)

Pilocarpine	7×10^{-6} (8)	6.7×10^{-6}‡	10^{-5}	2×10^{-6}

From competition curves with ^{3}H-atropine, apparent inhibition constants were obtained for the membrane-bound material, according to the equation $K_i = ID_{50}/(1+C/K_d)$ where C is the concentration of radioactive ligand and K_d its dissociation constant (the concentration of (±) ^{3}H-atropine was 4–6 nM). In the case of the soluble preparation, ID_{50}-values are reported because of the complex nature of the atropine-binding curve (Fig. 2). (±) ^{3}H-atropine concentration was 80 nM The following compounds had no effect on binding of labelled atropine at 20 µM: choline, *d*-tubocurarine, gallamine, α-toxin from *Naja naja nigricollis*, decamethonium, eserine, neostigmine, edrophonium and Tetram ((2-diethylamino)ethylphosphorothioic acid, 0,0-diethyl ester).

*All values are ID_{50}, that is the concentration of drugs which reduced ^{3}H-QNB binding by 50% (concentration of ^{3}H-QNB was 6×10^{-11} M). Reference numbers are given in parentheses

†Values given are either dissociation constants (obtained from the reciprocal of the quoted affinity constant (ref. 11 and personal communication from N. J M. Birdsall)) or ID_{50} values [9,10], all derived from ^{3}H-propylbenzilylcholine displacement.

‡Personal communication from N. J. M. Birdsall.

§Results from the study reported here.

antagonists. Analogous changes in binding properties have been observed in other systems after solubilisation, notably in the case of the nicotinic receptor[15]. These results suggest that the solubilised material which shows specific atropine binding was derived from the high-affinity component of the membrane preparation which is most likely to be the muscarinic receptor site.

Calcium levels in the brain underlie temperature control during exercise in the primate

ALTHOUGH it is known that the hyperthermia in man accompanying steady-state submaximal exercise is a regulated rise which is virtually independent of the ambient temperature[1], a fundamental question persists. What are the neural mechanisms involved in this regulated rise and in the ensuing hyperthermia encountered during severe work in the heat? It has been proposed that the elevation in the temperature set-point associated with fever has as its basic component a change in the hypothalamic balance between the essential cations, Na and Ca^2 (refs 2, 3) Is it possible that such a mechanism could underlie the shift in temperature set-point which occurs during exercise? To explore this idea, we undertook two types of experiments. First, an artificial cerebrospinal fluid (CSF) containing excess Ca^{2+} ions was infused into the third ventricle. Secondly the kinetics of endogenous Ca^2, as reflected by its retention or release into the third ventricle, was analysed We report here that Ca^{2+} ions, acting directly on the brain, can indeed attenuate or entirely block the hyperthermia of exercise without necessarily interfering with work output; further, the actual efflux of Ca^{2+} ions from the diencephalon increases markedly during the exercise-induced hyperthermia

Macaque monkeys were used, as the heat-regulating processes in man and subhuman primates are similar[4]. Two monkeys were seated in primate chairs and trained to exercise strenuously on a 'rowing machine'[5], using food pellets as reinforcers, so that they lifted up to three times their own body weight. Once the work rate had stabilised for an interval of 30 min, over several days, surgery was undertaken Following neurosurgical procedures[6] an array of three cannulae was implanted aseptically with the tips resting in the third ventricle, their patency was verified by the standard CSF pulsatile method On recovery, the monkeys were exercised again for two 30-min periods every day for 2 weeks before infusions were undertaken

When 0.5 ml of CSF was infused into the third ventricle at a constant rate over 10 min, the monkey continued to exercise, and its typical exercise-induced rise in colonic temperature persisted unabated. As shown in Table 1, however, the addition of excess Ca^{2+} ions to the infusion medium attenuated the hyperthermia in a dose-dependent manner In one monkey (*A*), the elevation in colonic temperature was reduced by 72%, yet total work output was reduced by only 37%. In another monkey (*B*), the rise in its body temperature due to exercise was virtually blocked (+0.2 °C) after the infusion of excess Ca^{2+} ions, yet the decline in total work performed was less than 25%. In both cases, when Ca^{2+} was infused into the monkey's ventricle in a sufficient concentration to induce a hypothermia, the monkey nevertheless exercised to a substantial degree On the basis of X radiographs taken in the sagittal plane, the differences in location of the tips of the cannulae may account for the differences in the animal's responses.

Table 1 Changes in colonic temperature from baseline control and total amount of work performed during exercise in neutral, cold and hot environments

Neutral (22 °C db)	Solution	Temperature change (C)	Total work (J per 30 min)
Monkey A	Control 5-ion	+1.45	2018
	Ca^{2+} 2.5 mM	+0.40	1258
	Ca^{2+} 10 mM	−0.45	1018
Monkey B	Control 5-ion	+1.35	2795
	Ca^{2+} 10 mM	+1.05	2556
	Ca^{2+} 15 mM	+0.20	2181
	Ca^{2+} 20 mM	−0.40	1045
Heat (35 °C db) Monkey A	Control 5-ion	+1.10	1338
	Ca^{2+} 2.5 mM	+0.45	1192
Cold (0 °C db) Monkey A	Control 5-ion	+0.55	2036
	Ca^{2+} 2.5 mM	+0.05	1367

To examine the effect of ambient temperature, we changed the environmental temperature of the monkey by a stream of hot or cold air blown into its chair 15 min before exercise and for the 30 min interval of exercise. In one monkey (*A*) we raised the ambient temperature to 35 °C and found that the excess calcium infusion (Table 1) greatly attenuated the exercise-induced rise in temperature without markedly affecting the amount of work performed. On the other hand, after the same monkey's ambient temperature was lowered to 0 °C (Table 1) on another day, its usual rise in temperature was abolished, but its work output was reduced by only 33%.

To determine whether a physiologically-induced change in endogenous calcium actually occurs within the diencephalon of the monkey as it exercises, we radiolabelled the structures surrounding the third ventricle by injecting 6.0–8.0 μCi of $^{45}Ca^{2+}$, in a volume of 6 μl, directly into the third ventricle on the day before an exercise experiment began. Before the 30 min of intense exercise, a series of 5-min push–pull perfusions of the tagged region were carried out at 15-min intervals in order that a stable washout curve of $^{45}Ca^{2}$ radioactivity could be generated. As soon as each monkey began to exercise, the efflux of $^{45}Ca^{2+}$ into the perfusate rose sharply from 100 to 300% (Table 2). At the same time, the typical exercise-induced rise of temperature occurred. Following the cessation of work, the augmented level of $^{45}Ca^{2+}$ in the perfusates (Table 2) continued for the next two to five perfusions, which corresponded to the interval of elevated body temperature.

Table 2 Percentage increases in $^{45}Ca^{2+}$ activity above the baseline d.p.m. in perfusate collected during 30 min exercise ($N = 2$) and in the 1 h post-exercise interval ($N = 3$)

	During exercise	After exercise
Monkey A	163%	131%
Monkey B	249%	283%

Our experiments provide new evidence that Ca^{2+} is involved in the shift in temperature which occurs during exercise. In both the rat and dog exercising on a treadmill, excess Ca^{2+} ions infused intracranially also attenuate the usual rise in the animal's temperature[8,9]. Therefore, it seems possible that the set-point for body temperature during exercise could be mediated by ions within the diencephalon[2], and that the set-point shifts upwards mainly by means of an unbinding, change in transport, or other activity of Ca^{2+}.

It is clear that the rise in central body temperature during exercise[9] can be modified or entirely abolished without necessarily incapacitating the animal or preventing it from performing a given work activity. These findings may have important implications for the clinical problems associated not only with the mechanism underlying heat stroke, but also with runaway hyperpyrexia.

Chorionic membrane as an extra-adrenal source of foetal cortisol in human amniotic fluid

STUDIES in animals suggest that foetal cortisol (F) may have an important role in foetal lung maturation and the mechanism of parturition. In man the situation is complicated by the greater permeability of the placenta to this hormone[1] and its intraplacental conversion to its biologically inactive metabolite, cortisone (E) (refs 2–4). Many other foetal tissues also convert F to E (ref. 5). As a result, human foetal blood contains a relatively large amount of E, and a lower F : E ratio. Recently, we observed that the F : E ratio of amniotic fluid is considerably higher than that of cord serum[6]. To explore this, the possible influences of the foetal kidney, skin, gastro-intestinal tract, lung and membranes were investigated; only the chorionic membrane was found to convert cortisone to cortisol.

Foetal tissues and fluids were obtained at hysterotomy in patients undergoing abortions for maternal indications from 11–22 weeks gestation, at elective Caesarean section and vaginal delivery at term and from two anencephalic stillbirths. Placenta and membranes were also obtained at vaginal delivery and amniotic fluids at amniocentesis. Endogenous F and E concentrations in fluids and homogenised tissues were assayed after Sephadex LH-20 column chromatography, by radiotransinassay using dog transcortin as described previously[7,8]. For the enzyme studies, pieces of tissue (0.5–1 g) were weighed, minced (except for amnion and chorion which were left intact) and added to 2.0 ml medium (0.9% saline, amniotic fluid, Krebs–Ringer bicarbonate glucose buffer, or phosphate buffer, *p*H 7.4). Since similar results were obtained for all media, later studies used saline only. Incubations were carried out for 2 h at 37 °C in glass counting vials containing tracer amounts (100 pg) tritiated F or E with or without added cold steroid. Following addition of 10 ml ethyl acetate the vials were capped and shaken vigorously for 10 min. Organic phase 5 ml was evaporated to dryness under air, dissolved in 0.2 ml methylene chloride: methanol 98 . 2 and applied to Sephadex LH-20 columns[8]. This procedure separated the F and E fractions so that the radioactivity in each could be determined. Conversion was calculated as 100 × c.p.m. $_{product}$/c.p.m. $_{product + substrate}$, less the control value calculated in the same way. Recovery of radioactivity as E+F was 80–100% that of the controls which consisted of tracer in medium prepared and incubated along with the tissues. Alternative controls consisted of identical tissue preparations placed in a boiling water bath for 5 min before

incubation. Identity of the products isolated from membranes and placenta was confirmed by recrystallisation to constant specific activity.

To simulate conditions *in vivo* more closely, four experiments were done in which layers of chorion and amnion from term placentas were placed over small shallow chambers 5 cm in diameter, tracer in 10 ml amniotic fluid was placed in the cavity lined by amnion, and the dishes were incubated for 2 h at 37 °C. Qualitatively similar though quantitatively about half the conversion seen in the routine incubation conditions was observed. When 10 ml saline was placed on the chorionic side, about one-third of the total activity passed through, mainly in the converted form. When the tracer was placed in the saline, about one-third passed into the amniotic fluid, again mainly as cortisol. These studies show that steroids can pass through the membranes from either the maternal of foetal side. It seems likely, however, that diffusion between uterus and chorion would be slow, whereas that between amnion (and chorion) and amniotic fluid would be hastened by the movement of the amniotic fluid itself.

Table 1 compares the endogenous concentrations of steroids found in cord serum and amniotic fluid. The F : E ratio was consistently higher in amniotic fluid than in cord serum at all gestational ages and rose with increasing age. F levels equalled or exceeded E levels in amniotic fluid from 25 weeks onward.

Table 2 shows the interconversion of F and E in several foetal tissues at various gestational ages. Conversion of F to E usually occurred while conversion of E to F was negligible, results in accord with previous studies[5] and with the endogenous concentrations shown in Table 3. The latter showed lower F:E ratios than serum at all ages studies.

In Fig. 1, the interconversions of F and E in chorion and in placental cotyledons are compared. The placenta showed high conversion of F to E throughout pregnancy. The reverse conversion occurred in the chorion with high values from 16.5 weeks until after labour had started, when they fell. The back reactions were consistently low averaging 65% for placental E→F and 10.2% for chorionic F→E.

Conversion in both tissues was greatly decreased by boiling. No differences were seen in conversion in either direction when 100 ng ml^{-1} F or E was added to the incubation medium of three placentas and three chorionic membranes (two from early pregnancy, one from late pregnancy). Little or no activity was seen in the amnion. When the chorionic membranes were examined microscopically, a layer of

*Excluding values from 12–16 5 weeks with F : E < 1.

maternal decidua was frequently adherent. Membranes from which this material was carefully scraped off retained their original activity The uterine wall was also found to contain the same or a similar enzyme and this is currently under investigation[9] No significant conversion of E or F was found when chorionic membrane from a single guinea pig killed under ether anaesthesia at 58 d gestation was incubated similarly.

The results of these *in vitro* studies are further substantiated by the endogenous levels shown in Table 4. A high F E ratio was seen in chorion and a much lower ($P<0.02$) one in placenta

These observations show that the chorionic membrane is a metabolically active tissue which behaves differently from placental cotyledons. The rise in chorionic conversion of E to F in early pregnancy corresponds to the rise at 15–20 weeks in amniotic fluid cortisol which we reported previously[11]. This chorionic conversion of E to F accounts also for the rising F : E ratio in amniotic fluid relative to cord serum observed through pregnancy The declining activity in labour accords with the lesser change in amniotic fluid F E ratio during labour despite the surge of F in cord blood associated with its spontaneous onset.

These results may explain the poor correlation we have found between amniotic fluid cortisol and lecithin or the palmitic : stearic ratio (ref. 11). Amniotic fluid cortisol is mostly diffusible[12] and is presumably taken into the foetus by swallowing or other means, possibly by diffusion into the lung. In sheep the lung is known to produce fluid steadily, making absorption of cortisol unlikely[13] In man there are few data and these are controversial[14]. Since the chorion in anencephalic infants seems to be normally active and since some of these infants breathe at birth, absorption of amniotic F through the lung or open cranium, might account for the relatively normal lung development seen in some anencephalics despite poor adrenal function[15].

The author thanks Mrs Doreen Vedady for assistance; Dr Mary Ellen Kirk of the Pathology Department for examining the membranes; and Dr Indra Antonipillai and Miss Mary Patchell for preparing the scraped membranes and assisting with the recrystallisation studies

Spectrin is absent in various tissue culture cells

A HIGHLY sensitive radioimmunoassay has been developed for human spectrin, one of the major components of the erythrocyte membrane[1–6]. We report here use of this assay on cells of human, monkey and rat origin and show that spectrin is absent from all cell lines studied, with the exception of erythrocytes. These findings seem important when models which invoke spectrin to regulate membrane fluidity,[7,8] or membrane-cytoskeletal interaction[9,10] are considered.

Spectrin is extracted from erythrocyte ghosts by alkaline solutions of low ionic strength[3] Purified spectrin consists of two high molecular weight polypeptides (molecular weights of 250,000 and 220,000) that are different from the myosin heavy chains[2,3] The properties that make spectrin of major interest for generalisation about a specific membrane protein are its abundance in the membrane protein fraction (approximately 25% of membrane protein)[1–5] and its localisation exclusively on the cytoplasmic side of the erythrocyte membrane[5,6] In addition, it is generally assumed that spectrin has an important role in regulating the mobility of transmembrane particles in the plane of the membrane[7,8] and that an interaction between spectrin and actin is involved in maintaining the shape and morphology of the erythrocyte[9,10] Particularly interesting in this respect are reports on the association of spectrin and actin and the effects of spectrin on the *in vitro* polymerisation of actin[11,12] Proteins with 'spectrin-like' properties (that is, high polypeptide molecular weight, solubility in low salt, and lack of myosin-like ATPase activity) have been found in echinoderm sperm[13], sea urchin eggs[14], macrophages[15] and *Acanthamoeba*[16] where they are also assumed to regulate the polymerisation of actin. These studies suggest that spectrin may be an ubiquitous protein in eukaryotic cells. Painter *et al* [10], however, were unable to detect spectrin by complement fixation in HeLa cells or in human fibroblasts, lymphocytes or platelets at a level higher than the background of the assay which was approximately 0.1% of the total cell protein. This assay was not very sensitive because even in erythrocytes spectrin accounts for only approximately 0.3% of the total cell protein[5] and because a 'spectrin-like' actin-binding protein has been found at the 1% level[15] Concentrations of spectrin corresponding to 5% of the myosin content of most non-muscle cells would not have been detected, so the data of Painter *et al* [10] do not exclude a potential

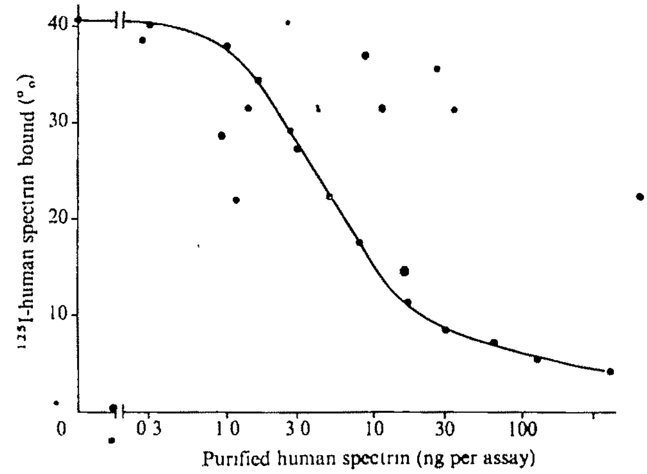

Fig. 1 Competition of unlabelled with ^{125}I-labelled human spectrin for binding to a specific antibody. Purified spectrin was iodinated in a reaction mixture (60 μl) to which 2 μg human spectrin, 0.5 mCi carrier-free Na ^{125}I, 25 μg Chloramine T, and 62 μg $Na_2S_2O_5$ were sequentially added[18]. After separation of the labelled protein and unreacted Na ^{125}I by gel filtration on Sephadex G-25, the radioactively labelled spectrin was rechromatographed on Sepharose 4B in order to eliminate some aggregated material. The specific activities of the preparations varied between 45 and 100 μCi per μg of spectrin Unlabelled human spectrin (0.2 ml) at various concentrations was preincubated (18 h at 4 °C) with 0.1 ml of a crude IgG fraction (21.4 mg protein per ml; diluted 8000-fold) of rabbit anti-human spectrin After addition of 0.1 ml ^{125}I-spectrin, equivalent to about 0.2 ng of protein, incubation was continued for 48 h Carrier rabbit IgG and enough sheep anti-rabbit IgGs were added to precipitate the formed antigen–antibody complexes maximally (24 h at 4 °C) Labelled spectrin and the various IgG-dilutions were kept in buffer containing 50 mM Na-phosphate, pH 8.0, 150 mM NaCl, 1 mM EDTA, 0.1 mM phenylmethane sulphonyl fluoride (PMSF), 0.02% Na N_3 and 0.2% bovine serum albumin (BSA). Unlabelled spectrin was diluted with 30 mM Tris-HCl, pH 8.0, 1% Triton X-100, 0.1 mM EDTA, 0.1 mM PMSF and 0.2% BSA The protein concentration of pure spectrin was determined using the extinction coefficient ε280 nm = 1.01 ml cm^{-1} in mg^{-1} (ref 2)

function of spectrin as a regulatory protein of the microfilament system.

In order to increase the sensitivity of a spectrin-specific assay we have developed an immunological competition assay in which unlabelled spectrin competes with highly radioactively labelled spectrin for binding to a limited amount of spectrin-specific antibody (Fig. 1). Spectrin was purified from human erythrocyte ghosts by standard procedures[17]. Gel filtration on Sepharose 4B removed not only impurities but also erythrocyte actin. The resulting preparation showed only the two high molecular weight polypeptides even on heavily overloaded polyacrylamide gels containing sodium dodecysulphate. Antibodies against native spectrin were raised in rabbits The antisera formed a single precipitin band on immunodiffusion against human spectrin.

The radioimmunoassay (Fig. 1), which to our knowledge is the first one for spectrin, can detect as little as 5 ng of erythrocyte spectrin per ml. Thus in extracts of human cells this assay should detect spectrin at levels as low as 10^{-4}–10^{-3}% of total protein.

Table 1 summarises our results on the radioimmunological detection of spectrin in extracts of various tissue culture cells of human and monkey origin Spectrin could not be detected antigenically in any of the cell lines studied, including both fibroblasts and epithelial cells. HeLa cells, grown either in suspension or in monolayer were devoid of spectrin, in spite of the differences in morphology and cell shape present in the different growth conditions. In these cells the assay would detect spectrin-cross-reacting material if there were more than approximately 250 molecules of spectrin in a single cell. Spectrin added exogenously to the cell homogenates was easily detected in the radioimmunoassay and the estimated values were in good agreement with the known input (see Table 1). Thus potential loss of spectrin due to proteolytic degradation during the long incubation time used can be ruled out. For intact erythrocytes Bretscher[5] reported a ratio of 45 mg haemoglobin to 0.6 mg membrane proteins; assuming about 25% of the mass of the membrane proteins to be spectrin leads to a value < 0.32% of the total erythrocyte protein being spectrin Our estimation (0.24%) is in good agreement with this calculation, suggesting that in the conditions used spectrin is almost completely extracted from the cells

In contrast to an earlier antibody preparation[20], our rabbit anti-human spectrin sera showed a weak but reproducible precipitation with spectrins purified from sheep or rat erythrocytes. This cross reactivity allowed use to use the anti-human spectrin sera also for the estimation of spectrin in different tissue culture cells of rat origin. In this system the heterologous antisera must be fivefold more concentrated to give comparable binding. The sensitivity in these conditions allows the estimation of about 50–100 ng of rat spectrin per ml In the homogenates of four different rat cell lines studied (2 cloned lines of SV40 transformed embryo fibroblasts, the glial cell clone 6, and a line derived from a mammary

Washed cells were disrupted at ice-bath temperature by 30 strokes in a tight fitting homogeniser The buffer used contained 30 mM Tris-HCl, pH 8.0, 1% Triton X-100, 0.1 mM EDTA and 0.1 mM PMSF. After 30 min on ice, unsolubilised material was removed by centrifugation (20,000g, 15 min, 4 °C) and 0.2-ml aliquots of the supernatants were tested, in parallel with purified spectrin as standard in conditions as described in Fig. 1. Solubilisation of erythrocytes was almost complete Examination of the small sediment by gel electrophoresis in SDS showed only traces of the characteristic spectrin doublet indicating that much less than 10% of the spectrin remained unextracted This was also indicated by the results of the radioimmunoassay (see text). Protein was assayed by a modification of Lowry's procedure[19]

* Grown as monolayer

† Grown in suspension

adenocarcinoma) no spectrin could be detected at a level higher than $3 \times 10^{-3}\%$ of the extracted protein

In summary, it seems that erythrocyte-type spectrin is not an ubiquitous protein, although we can not exclude the unlikely possibility that non-erythrocyte cells contain spectrin(s) which are immunologically unrelated to erythrocyte spectrin Spectrin is probably an important protein of the erythrocyte—and perhaps some yet unidentified cells—and probably has an important role for the special membrane of this highly differentiated cell.

We thank Dr U Groeschel-Stewart of the University of Darmstadt for help with preparation of spectrin antibody

Precocious development of foetal glucuronidating enzymes induced by glucocorticoids in culture and *in utero*

CONJUGATION with glucuronic acid is the major pathway in vertebrates by which harmful organic compounds are detoxicated. It ensures the excretion of excess endogenous compounds such as steroid hormones, catecholamines and bilirubin, and of a great range of toxic xenobiotics such as drugs, pesticides, industrial pollutants and their metabolites[1]. Glucuronidation, however, is virtually absent in the early mammalian foetus and approaches adult levels only in the perinatal period, putting the foetus and newborn at considerable risk from unwise medication or exposure to environmental contaminants. This susceptibility has been demonstrated frequently, often with fatal results[2,3]. Defective glucuronidation of endogenous bilirubin is a major cause of human neonatal jaundice and can lead to infant death[4]. Attempts have been made to induce the responsible microsomal enzyme(s), UDP-glucuronyltransferase (EC 2.4 1.17), in cases of prematurity, genetically defective enzyme formation or poisoning by glucuronidogenic compounds; administration of xenobiotic inducers such as phenobarbital has had limited success in neonates and the term foetus[2-5]. Adequate treatment of such conditions, however, requires knowledge of endogenous compounds which induce the enzyme perinatally. We report here the first evidence in foetal mammalian tissue of precocious development of UDP-glucuronyltransferase activity and of overall glucuronidation brought about by known compounds of endogenous nature. These findings provide insight into the perinatal development of this important enzyme.

We have already established that glucocorticoids invoke precocious development of the transferase in chick embryo liver. As that work involved pituitary grafting and continuous infusion of hormone *in ovo*, its extension to the mammalian foetus required simpler techniques. Operative stress to the mother, resulting in excessive corticosteroid production, would make controls difficult. We have therefore adopted two approaches: exposing the foetal liver to glucocorticoids in culture and *in utero* by simple maternal injection.

Culture methods were as described previously[6]. Exposure *in utero* was achieved by injecting pregnant rats intraperitoneally on days 14 and 15 of gestation with the steroid dissolved in arachis oil; control pregnant rats received arachis oil only. UDP-glucuronyltransferase activity towards *o*-aminophenol was assayed as described previously[6] but, because the mammalian liver enzyme is markedly activable and the activation is age dependent, assays were carried out in each experiment over a range of digitonin concentrations (0–0.2% w/v) covering zero to beyond optimal activation. Overall glucuronidation, for which the intact cells synthesise their own UDP-glucuronic acid[1], was measured in sliced tissue, as previously[6].

We found transferase activity towards *o*-aminophenol in the naturally developing rat foetus to be virtually zero from days 14–17 of gestation, increasing sharply on day 17 to peak on day 20. This held for all degrees of activation of the enzyme studied. We then exposed 14-d rat foetal liver explants to 2 μM corticosterone or cortisol in culture in a protein-free defined medium After 3 d in culture transferase activities had reached values normally found in 18–19-d foetal liver *in utero*, almost the 'adult' levels. Dexamethasone, 2 μM in the culture medium, increased the values to full adult male levels. 'Control' 14-d foetal livers, left for 3 d *in utero*, possessed negligible levels, as did those cultured without the added glucocorticoid (Table 1).

Pulsing the glucocorticoid-exposed cultures for 5 h with 3.5 μM cycloheximide inhibited ^{14}C-leucine uptake and prevented development of transferase activity; both processes returned within 2 d to the rates observed in non-pulsed cultures. The data also indicated that general protein synthesis proceeded at similar rates in cultured liver whether exposed to glucocorticoids or not; further, after culturing for 2 d without glucocorticoids, subsequent exposure to them evoked transferase production as rapidly as in fresh cultures. The glucocorticoids were thus not needed to maintain viability of the cultured tissue but seemed responsible for the specific increase in transferase. Other steroids (not glucocorticoids), exhibited no effect.

Table 1 Development of UDP-glucuronyltransferase activity in foetal rat liver exposed to glucocorticoids

Treatment of 14-d foetal liver sample	nmol *o*-aminophenyl glucuronide formed per mg protein per h	
	In culture	*In utero*
Fresh (untreated)	—	<2.0
After 3-d control treatment	2.8, 2.2	2.4, 2.7
After 3-d cortisol treatment	25.8, 25.0	7.0, 7.6
After 3-d dexamethasone treatment	45.3±9.8 (4)	28.4, 30.8

Liver fragments were cultured on rafts over Eagles' MEM supplemented with L-glutamine and penicillin–streptomycin mixture[6] and containing 2 μM steroid where required. Pregnant rats were injected intraperitoneally with 8 mg cortisol or 0 3 mg dexamethasone in arachis oil per day on the days 14 and 15 of gestation. Control rats received arachis oil only; liver transferase levels in control foetuses were identical with those in foetuses from uninjected mothers. Adult male rat transferase levels were 30–40 of above units. Transferase activities were assayed[6] in 'optimal' activation conditions (see text). Results above are from typical experiments. Each result is from a pool of at least 4 foetal livers; where appropriate, s.e.m. is given, with number of experiments in parentheses.

Table 1 also shows the effect on foetal liver transferase of maternal injection of glucocorticoids. As glucocorticoids cross the rat placenta[7], and dexamethasone is less likely to be inactivated by the mother[8], the precocious development of transferase activity following injection of cortisol or dexamethasone presumably reflects the action of these compounds on the foetal liver *in utero* as described above during culture. Transferase stimulation was found to be linearly dose dependent.

Overall glucuronidation, as measured in foetal liver slices or explants, also precociously increased after exposure to the glucocorticoids in culture or *in utero* We have induced precocious transferase activity to several substrates, endogenous and xenobiotic, this way but stimulation towards others, apparently those developing later in the perinatal period, have so far resisted our efforts both in culture and *in utero*.

We have thus reported the first evidence in foetal mammalian tissue of precocious development of UDP-glucuronyltransferase activity and of overall glucuronidation brought about by known compounds of endogenous nature. These compounds are glucocorticoids. Their effect is reproduced by the long-acting synthetic glucocorticoid, dexamethasone. They evoke high transferase activity in foetal rat liver from negligible levels, both in culture and *in utero*. They act directly on the liver, and require protein synthesis for their precocious induction of the transferase. Their involvement perinatally is consistent with the peak in corticosterone levels observed in foetal rat plasma on gestational day 19 and with the maternal increase on day 18 (refs. 9–11) We therefore suggest that the natural perinatal development of glucuronidation and UDP-glucuronyltransferase activity towards certain substrates is brought about by glucocorticoids

Liver protein metabolism response to cold in genetically obese (*ob*/*ob*) mice

THE response of obese (*ob*/*ob*) mice to the cold is reportedly impaired to the extent that they die 3–6 h after exposure. They also increase their oxygen consumption to a lesser extent than do their lean littermates in response to the cold[1,2] As *ob*/*ob* mice have increased insulation due to excess body fat and respond in this way to the cold before the phenotypic expression of obesity, impaired thermogenesis seems to be a primary feature of this strain of genetic obesity Adult obese Zucker rats also show impaired thermogenesis when exposed to cold and their mean survival time is 28 h (ref 2). The nature and control of this thermogenesis and its possible relevance to energy balance is unclear The involvement of protein metabolism and the energy cost of protein turnover has been postulated by[1–6]. Acclimatisation to the cold increases protein turnover in rats[6] and in lean (*Ob*/+) mice (unpublished observations).

We report here a comparison of rates of amino acid incorporation into liver protein by lean (*Ob*/+) and obese (*ob*/*ob*) mice. Amino acid incorporation was depressed in the obese mice, in response to a cold environment when compared to their lean littermates.

Female lean and obese mice, age-matched (70±5 d) were kept at 22 °C and fed freely until required. Animals were then placed in a 4 °C environment with access to food, and killed in groups of four, from zero time to 24 h after cold exposure. The length of the comparative study was

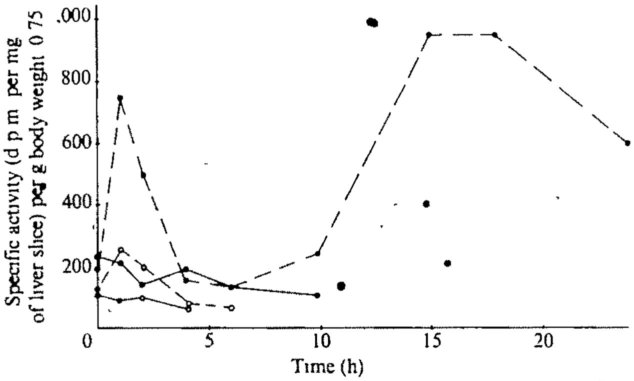

Fig. 1 Changes in liver amino acid incorporation following exposure to 4 °C in lean and obese mice with and without food. ○——○, obese without food, ○ - -·- ○, obese with food, ●——●, lean without food; ●-·-·-●, lean with food. Animals were killed by cervical dislocation, the livers rapidly removed, placed on a Petri dish packed with ice and three or four slices approximately 1 mm thick were cut with a razor blade The slices from each liver were placed in individual flasks with 2.5 ml of Krebs phosphate Ringer solution (100 parts 0.9% NaCl; 4 parts 1.15% KCl; 3 parts 1.22% $CaCl_2$; 1 part 3.82% $MgSO_4$ 7 H_2O and 20 parts 0.1 M phosphate (Na) buffer *p*H 7.4) The buffer was prepared from 0.1 M $NaH_2PO_4 2H_2O$ (14%) and 0.1 M $Na_2HPO_4 2H_2O$ (86%). 1 μCi of L-4,5-^{3}H-leucine (55 Ci mmol^{-1}) was added, and after oxygenation the slices were incubated at 37 °C for 1 h. The incubation was stopped by removal of the slices, which were blotted and homogenised in TCA (100 g l^{-1}). The precipitate was washed twice with a saturated solution of unlabelled leucine in TCA (100 g l^{-1}) to remove any unincorporated labelled leucine TCA was removed by washing with ether and the precipitate solubilised in 3 ml of 0.3 M KOH. The activity of the protein was measured by liquid scintillation counting and protein determination was by Autoanalyser[8].

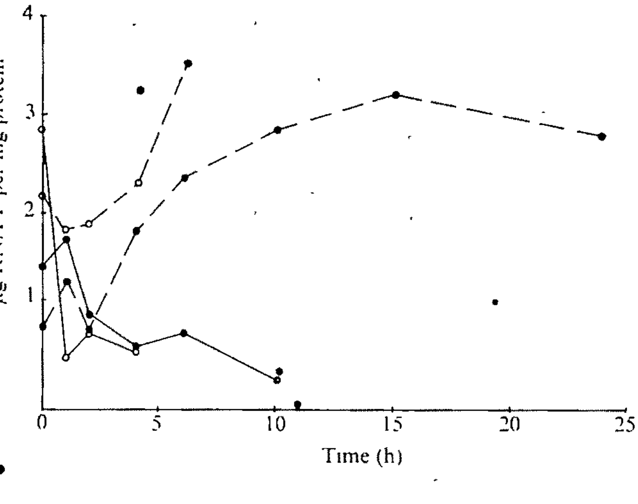
Fig. 2 Liver RNA to protein changes following exposure to 4 °C in lean and obese mice with and without food. ○ —— ○, Obese without food; ● —— ●, lean without food; ○ -·- - ○, obese with food; and ● -·- ●, lean with food.



controlled by the survival time of the obese (*ob/ob*). The livers were immediately removed, and amino acid incorporation into protein was measured as described in Fig 1 The rest of the liver was used for RNA determinations[7] and the residual protein pellet was solubilised in 5 ml of 0.3 M KOH for protein determination by Autoanalyser[8].

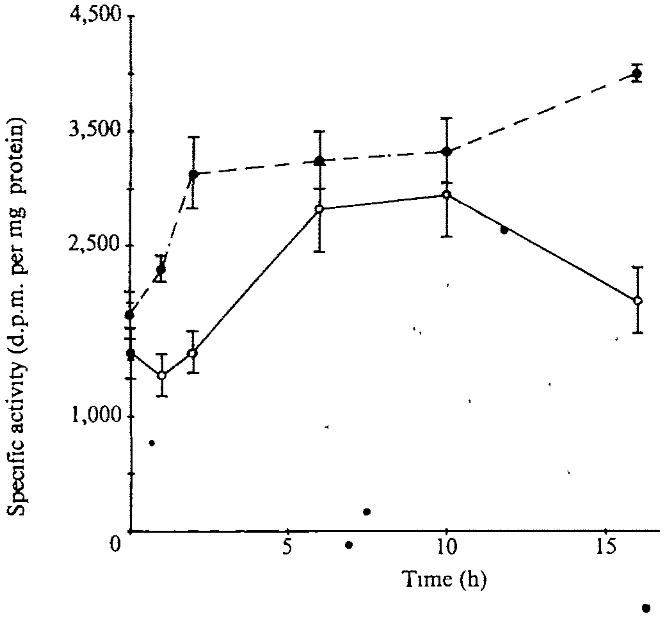
Ratios of RNA to protein in livers from obese mice were significantly greater ($P<0.001$) than those of lean mice at time zero. This was confirmed by monitoring the response to cold without food (Fig. 2). This suggests that there is some restriction on the effective use of RNA species after the transcription stage of protein synthesis in obese mice.

The ratio of RNA to protein was significantly greater in both lean and obese animals after exposure to cold (Fig. 2). But after 4 h, only the ratio for the lean animals was significantly greater ($P<0.02$) than the corresponding ratio measured at time zero

Amino acid incorporation in the lean mice was significantly increased after 1 h of exposure and the percentage increase over zero values was greater in the lean than the obese mice, whether expressed directly as specific activity of liver slice protein or as (Fig. 1) specific activity per unit of body wt$^{0.75}$. The results are expressed as the latter because if protein turnover is contributing to thermogenesis, the ability of the heat produced by the process—to maintain body temperature—must be related to metabolic body size (body weight$^{0.75}$). Obese mice were dead within 8 h and so a second increase in amino acid incorporation, like that found in the lean mice, could not be demonstrated. Either the failure of some other process caused a decrease in body temperature so that the suppression of amino acid incorporation was a secondary effect, or the increase of amino acid incorporation is critical to the maintenance of body temperature. The latter seems more likely as there is a significant difference between lean and obese mice with food and between lean without food after 1 h of cold exposure, when body temperature will not have fallen sufficiently to explain the decrease in amino acid incorporation[2].

The secondary increase in incorporation in the lean animals can be explained by the increase in RNA, whereas the primary increase in incorporation must be controlled by other factors, probably hormonal. But even though RNA levels in the obese mice after 6 h were significantly increased ($P<0.001$) (Fig. 2) there was no associated increase in amino acid incorporation.

Fig. 3 Changes in liver amino acid incorporation following a meal in lean and obese mice ○——○, Obese; ●–·–·–●, lean. Animals were starved for 48 h, and then fed Porton mouse diet (Christopher Hill) for the remainder of the experiment. All animals after 1 h had full stomachs. Amino acid incorporation was measured as in Fig. 2.



Unfed mice were used to find whether the increased food intake, by cold adapted animals[9] and specifically by lean mice (unpublished observations) was essential for adaptation to the cold. In these circumstances neither lean nor obese mice could adapt to the cold, the obese mice died 2 h earlier than in the previous study and the lean animals died after 11 h of exposure. In neither lean nor obese mice was there an increase in amino acid incorporation and the RNA to protein ratio decreased in both groups (Figs 1 and 2).

These observations seem to support the hypothesis that food has a thermic effect[10]. But in a study performed at 22 °C when lean and obese animals were starved for 48 h and fed (Figs 3 and 4) there was only a twofold increase in amino acid incorporation, compared with the fivefold increase observed in the cold We therefore suggest that food contributes directly to thermogenesis, but that the large increase observed in the cold cannot be explained entirely in this way There must be simultaneous hormonal stimulus of thermogenesis and amino acid incorporation. No hormonal stimulus was observed in the cold without food presumably because substrate availability was rate limiting.

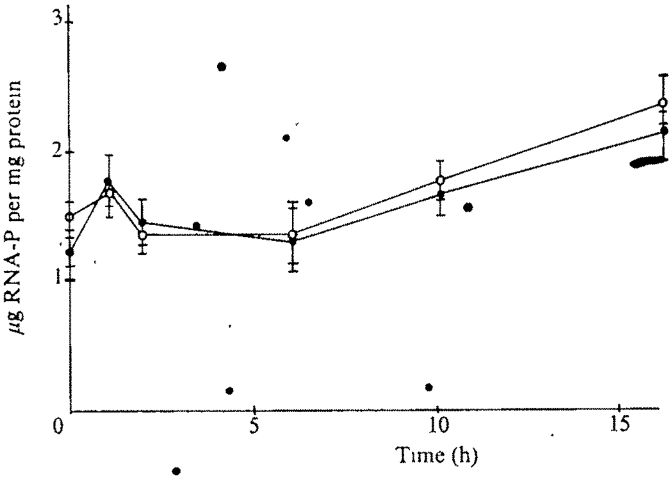


Fig. 4 Liver RNA to protein changes following a meal in lean and obese mice. ○, Obese; ●, lean.

RNA to protein ratios for lean and obese mice were not significantly different for the starved animals, and were only slightly increased after feeding (Fig. 4). The levels in obese mice had decreased to those of lean mice after 48 h of starvation, which agrees with the observation that the former levels decreased to the latter values if mice were exposed to the cold without food. This supports the argument that RNA levels are high in the livers of obese mice because of an impaired protein synthesis. In starvation when protein synthesis is severely restricted due to lack of substrate, the effect of such an impairment which increases RNA would be negated.

In an obese animal placed in the cold without food, shivering thermogenesis would make such a major demand on substrate that protein synthesis would be restricted in a similar manner. Amino acid incorporation in the obese in response to food (Fig. 3) was depressed in comparison with the lean and was not so prolonged, which may affect energy balance by depressing energy expenditure thus contributing to the obesity.

The difference between amino acid incorporation in the livers of lean and obese mice is not the only consequence of exposure to the cold Jansky[11] has shown in cold-adapted rats that the liver only contributes 25% of non-shivering thermogenesis (NST), the remainder coming from muscle (50%), digestive tract (10%), brown fat (10%) and other tissues (5%).

It is not known whether protein metabolism in these tissues can be implicated in NST Also, the involvement of futile cycles in thermogenesis has been postulated[12]. Specifically, James and Trayhurn[13] have implicated a futile cycle in glucose metabolism found in skeletal muscle, the impairment of which in obese subjects reduces their ability to produce heat, either in a cold environment or after food. They state that[13], "The control and interrelationships between different futile cycles are at present unclear".

Bray *et al.*[14] demonstrated that exposure to the cold does not lower the body temperature of obese (*ob*/*ob*) mice if they are pretreated with triiodthyronine, and that the body temperature of lean mice decreases if they have been made hypothyroid by prefeeding with propylthiouracil. This suggests thyroid hormones as likely candidates for the hormonal control. Jansky[11] demonstrated that noradrenaline also stimulates thermogenesis, so there are at least two candidates for hormonal control. The relative importance of each is unclear especially as the calorigenic effect of noradrenaline depends on thyroid status[15].

Contractile activation in slow and twitch muscle fibres of the frog

VERTEBRATE slow and twitch skeletal muscle fibres differ qualitatively in many respects and constitute functionally distinct motor systems[1,2] Little is known, though, of the respective contractile activation properties. Since triad contacts between transverse (T) tubules and sarcoplasmic reticulum (SR), thought to be the pathway for activation of twitch fibres, are nearly identical in frog twitch and slow fibres[3], similar processes would be expected to lead to Ca^{2+} release from the SR following T-tubule depolarisation in both muscle types. We describe here voltage-clamp studies of activating threshold contractions in slow and twitch fibres[4,5]. Activation kinetics in these physiologically very different fibre types are remarkably similar. Thus, a given membrane potential change may result in an equivalent amount of Ca^{2+} delivered to both slow and twitch myofibrils Once activated, each fibre type would shorten at its characteristic velocity[6], probably determined by the rate of actomyosin cross-bridge turnover[7].

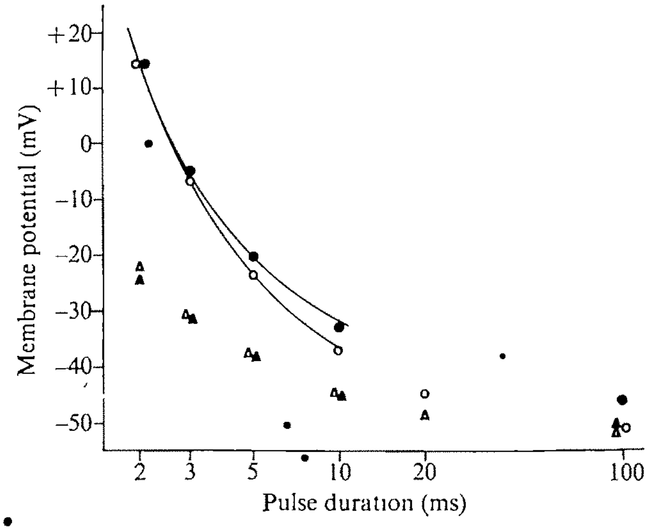
Experiments were performed at 9 °C on sartorius twitch fibres and pyriformis slow fibres of English frogs (*Rana temporaria*). Normal Ringer contained 115 mM NaCl, 2.5 mM KCl, and 1.8 mM $CaCl_2$ buffered at *p*H 7.0 with 1 5 mM Na-phosphate; twitch fibres studied were poisoned with tetrodotoxin (10 μg ml^{-1}).

Generally we used the methods described by Costantin[5]. Membrane potential was measured differentially between an internal microelectrode and another 20–30 μm away outside the fibre Time constants of these electrodes and command pulses to the clamp circuit were matched (~150 μs), and current-passing microelectrodes were shielded with conducting paint and then insulated These procedures facilitated rapid membrane potential changes using high resistance electrodes necessary for the slow fibre experiments[8]. Holding potential was –90 mV throughout.

For a given pulse duration, the threshold membrane potential was taken as that at which discrete sarcomere shortening was visually detected, the region under observation being between the microelectrodes and in the plane of focus through the upper or lower surface of the fibre. For the briefest pulses, a range of up to 5 mV was occasionally required to decide on an unequivocal contraction, threshold was taken as the midpoint of such a span. This was more troublesome in slow fibres due to the low shortening velocity.

In a frog twitch fibre the amplitude of a step depolarisation eliciting a threshold contraction increases markedly as

Fig. 1 Strength–duration curves for twitch (●, ▲) and slow (○, △) muscle fibres. Circles represent means from 14 slow and 18 twitch fibres studied at 9 °C; triangles are from 21 slow and 18 twitch fibres at 20 °C Smooth curves were calculated with the equation[4]: $(V_T+C)t_c = B_T$, where V_T is threshold membrane potential (mV), t_c is pulse duration (ms), and C and B_T are empirical constants determined as described by Costantin[5]. B_T = 127±4.7 mV.ms (s e.m.) and C = 49 1±0 9 mV for slow fibres, B_T = 116±5.6 mV.ms and C = 43 5±1.0 mV for twitch.



pulse duration decreases, resulting in a familiar smooth strength–duration (S–D) relation[4,5]. Such S–D curves for slow and twitch fibres in normal Ringers are shown in Fig. 1. Clearly, at either temperature, the relations for slow and twitch fibres are of the same form. At 9 °C the curves superimpose at short times and diverge to near-rheobase 100-ms values of -51 ± 0.8 mV (s.e m.) in slow fibres and -46 ± 0.8 mV in twitch. At room temperature the curves for both fibre types are indistinguishable.

Although the S–D curve reflects events leading to Ca^{2+} activation of thin filaments, it is not clear which processes determine its exact form. During a long pulse, the situation is complicated, since both release and reuptake of Ca^{2+} by the SR will occur, and rheobase represents the steady-state with one process just balancing the other. Uptake of Ca^{2+} during a short pulse and for a few ms afterwards should be negligible[9], so that only processes leading to Ca^{2+} release should fix the requirements a brief depolarisation must satisfy to activate contraction.

One starting point, then, for interpreting the comparison of S–D relations is to assume that for short pulses; a threshold contraction results from release of a particular amount of Ca^{2+}. Rate limiting steps leading to release could occur at the triad, presumably where T-tubule membrane potential is sensed by the SR, or at the sites of Ca^{2+} release themselves. Thus, 2 and 3 ms thresholds at 9 °C should be most indicative of gross differences in the activation kinetics in slow and twitch fibres, but such differences are not seen.

Another similar experiment involves studying the temporal summation of two sub-threshold depolarisations in activating a contraction[4,5]. This yields information on the time course of decay in 'mechanical excitability' induced by the first pulse The fraction of excitability remaining at any time after the first pulse can be estimated by comparing amplitudes of a second test pulse (V_2) eliciting a threshold contraction and of a single threshold pulse of identical duration (V_T; see legend and insert in Fig 2) To maximise the voltage range covered by V_2, brief first pulses (80–90% of threshold) were followed with test pulses of identical duration (3 ms in twitch; 5 ms in slow).

Results from one twitch and two slow fibres are shown in Fig 2. In all fibres the level of mechanical excitability decayed rapidly after the first pulse with a half-time of about 1 ms (Fig. 2*a*). All fibres then showed a slower phase of decay, but with vastly different rates in slow and twitch. Twitch fibre excitability decayed with a 5–6-ms time constant, threshold returning to the original V_T value within about 20 ms, whereas the excitability of the slow fibres returned to the normal level with a time constant of more than 300 ms (Fig. 2*b*). No such very slow component was seen in three other twitch fibres studied.

As argued by Costantin[5], the fast initial decay in a twitch fibre probably represents rapid voltage-dependent deactivation of Ca^{2+} release following repolarisation. Since kinetics of mechanical activation, as evidenced by the S–D curves, seem indistinguishable in the two fibre types, the fast decay of excitability should also be alike in both, and this seems to be so.

Most striking are differences in the slow phase of excitability decay. For twitch fibres, this decay is of the proper time course to represent background Ca^{2+} removal by the SR[5,10]. Since a slow fibre has less SR than a twitch fibre[11], the net rate of Ca^{2+} removal may also be lower, and the very slow decay might then also represent Ca^{2+} uptake. Preliminary experiments measuring tension produced by voltage-clamped short cruralis[12] slow fibres support this idea. After long (1–3 s), just suprathreshold depolarisations, relaxation proceeded with a half time of 0.5–1.0 s.

From these results it seems that the kinetics of mechanical activation in frog slow and twitch fibres are quite alike. Furthermore, buffering the external Ca^{2+} concentration at $< 10^{-8}$M with 2.5 mM EGTA and 10 mM $MgCl_2$ leaves the S–D curves of both fibre types essentially unchanged[13], again suggesting a common mode of activation through release of Ca^{2+} by the SR.

Although activation in an overall sense is kinetically similar, the underlying molecular processes in each fibre type may not be identical. Interestingly, the drug dantrolene sodium, which affects the S–D curve of frog twitch fibres[14], possibly by interfering with Ca^{2+} release[15], has no effect on the S–D relation for slow fibres (unpublished data).

If identical brief depolarisations lead to the same amount of Ca^{2+} released in both fibre types, one might expect, neglecting possible differences in thin filament Ca^{2+} sensitivities, similar numbers of perhaps both SR Ca^{2+} release sites as well as T-tubule : SR triad contacts in both types. Disposition of the internal membranes in slow fibres has been clarified with high voltage eletrcon microscopy[16–18]. Though preliminary, these results suggest that the number of triad (or dyad) 'feet' bridging the T : SR junctional gap in a given volume of muscle fibre may be quite similar for twitch and slow (C. H. Bailey and L. D. Peachey, personal communication). If the feet do subserve an important step in mechanical activation[19,20], similarities in activation kinetics described here may have an anatomical basis, and it may not be necessary to speculate on alternative pathways of activation in frog slow fibres.

We acknowledge the encouragement and support of the late Dr L. L. Costantin and Dr W. K. Chandler. This work

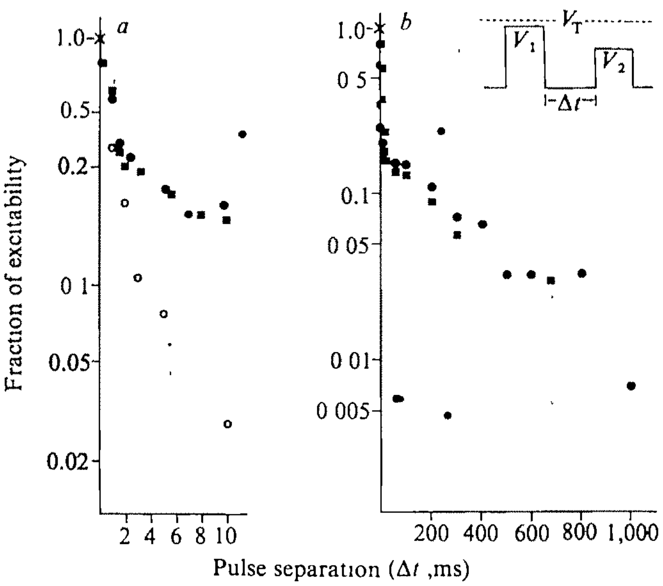


Fig. 2 Decay of mechanical excitability at 9 °C in twitch and slow fibres after a brief subthreshold pulse (V_1). Fractions of excitability remaining at a time Δ*t* were estimated as: $[V_T - V_2(\Delta t)]/[V_T - V_2(0)]$, where $V_2(\Delta t)$ is membrane potential during the V_2 test pulse with pulse separation Δ*t*, and $V_2(0)$ is membrane potential of V_2 with zero pulse separation. V_T is the usual threshold membrane potential for a single pulse of the same duration as V_1. V_T was checked periodically during the experiment and did not change by more than a few mV. V_1 and V_2 pulses were of the same duration throughout: 5 ms in slow and 3 ms in twitch fibres, *a*, Fast excitability decay in one twitch (○) and two slow fibres ●, (■) Cross represents value shared by all fibres. Twitch fibre threshhold returned to normal in about 20 ms. *b*, Slow excitability decay in the two slow fibres of (*a*). Threshold returned to the original V_T level only after 1000–2000 ms.

Is thyroxine a regulatory signal for neurotubule assembly during brain development?

TUBULIN, the basic subunit of microtubules[1], may be assembled, *in vitro* directly from crude brain supernatants to microtubule-like structures[2,3]. We have used this methodology to measure the initial rate of assembly *in vitro* in crude brain supernatants prepared from rats of different ages. Previous results[4,5] provided clear evidence that at a late foetal stage or just after birth the concentration of tubulin in the brain is not the rate limiting factor for microtubule assembly. We assumed therefore that a factor other than tubulin is necessary to initiate the assembly process and that this factor is limiting in young brain. On the other hand, brain maturation is a slow post-natal process in the rat and it is generally believed that this process is under thyroid hormone control. We report here that microtubule formation during brain development requires the presence of an initiation factor and that the onset of this factor is under thyroid hormone control.

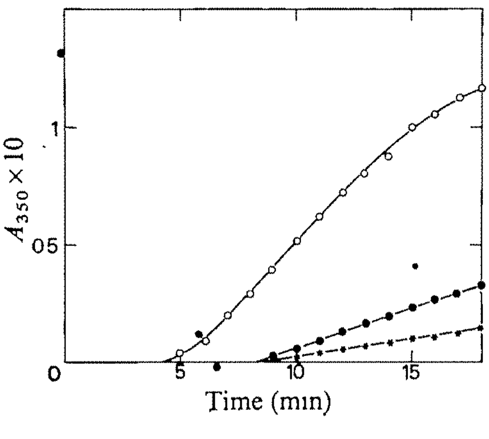
Thyroid hormones have a profound effect on brain development; for example, congenital hypothyroidism produces severe mental retardation (cretinism) in man and animals. Treatment with thyroid hormones after birth accelerates the development of innately organised behaviour and of electrocortical activity[6]. Histological alterations observed during hypothyroidism[7–9] mainly concern the development of cellular processes and dendrites. These effects are associated with biochemical changes; the protein content and protein synthetic activity of the brain are reduced[10,11]. None of these observations, however, is directly related to a possibly more specific effect of thyroid hormones during brain development—the increase in the number of connections, for instance of dendrites spines of cortical neurones and of Purkinje cells in the cerebellum[7].

Microtubules are good markers of brain connections as they are very abundant in these structures[12–14]. At early stages of development, however, tubulin polymerises very poorly *in vitro* in conditions described by Weisenberg[2] and Shelanski[3]. Figure 1 shows, for instance, that in 3-d-old rat brain preparations the rate of *in vitro* microtubule assembly is markedly lower than in those of 15-d-old rats, and also that the lag period is increased; the critical concentration[15] of tubulin at which microtubule assembly can be observed *in vitro* was also increased (not shown). This difference in rates depends on the fact that, at early stages of development, a factor which is needed to initiate the assembly process, is limiting[16,17]. This factor has been tentatively identified[16] with the protein described by Weingarten *et al.* [18]. Another possibility would have been that the young brain supernatants contain an inhibitor of the microtubule assembly; this possibility was eliminated, as reported before[5], by mixing supernatants from 30-d-old and newly born rats: there was no inhibition of assembly in these conditions. In addition, mixing supernatants of newly born rats with very small amounts of sonicated fragments of adult preparations resulted in a normal rate of assembly[5].

Severe hypothyroidism can be produced in the rat by treatment with antithyroid drugs during pregnancy and after birth[7]. Pregnant females were force-fed from the 18th d of gestation until 15 d after delivery with 3-methylthiouracil (MTU); thus MTU was supplied to the foetus during pregnancy and to the newborn rats through the milk of the mother during lactation. At 15 d after birth the newborn rats were clearly hypothyroid—the body weight was 28.8±2.18 g (control rats 34.16±0.3 g). The brain weight was also reduced but only by 20%. The tubulin contents of these supernatants evaluated by a modification[4] of the ^{3}H-colchicine binding method[19] were very similar (controls, 2.87 mg; MTU-treated 2.74 mg tubulin per g wet weight).

In vitro microtubule assembly in brain supernatants was followed using the turbidimetric method of Shelanski *et al.*[3] Figure 1 shows that, after MTU treatment, microtubules polymerised very poorly *in vitro* when the same tubulin concentration was used in the assays (15-d-old MTU treated rat brain supernatants) and in the controls (15-d-old normal rat brain supernatants). The initial rate of assembly markedly decreased and the latency increased. The kinetics of assembly ressembled those observed 3 d after birth, suggesting that hypothyroidism produces a retardation or a blockage of the ability of tubulin to assemble to microtubules. These results suggest that thyroid hormones have a greater effect on the

Fig. 1 Turbidimetry time course of supernatants from 3 and 15-d-old euthyroid rats and 15-d-old hypothyroid rats. The supernatants were obtained after homogenisation of rat brains in a reassembly buffer containing: 0.1 M morpholino-ethane sulphonate (*p*H 6.5, 1 mM GTP, 0.5 mM $MgCl_2$, 1 mM EGTA, 0.1 mM EDTA, 1 mM β-MSH at 4 °C and centrifugation at 105,000*g* for 1 h at 4 °C. Glycerol (final concentration 4 M) was added after centrifugation. Turbidimetry (*A* at 345 nm) time course at 37 °C was followed with supernatants dilutions containing the same (0.940–1.040 mg ml^{-1}) amounts of tubulin, measured as before[12]. 15-d-old hypothyroid rats were obtained by a treatment of the mothers with MTU from the 18th d of gestation (50 mg per day given by force feeding[3]) until the day of killing. ★, 3-d-old euthyroid rat brain supernatant (tubulin 0.94 mg ml^{-1}; ○, 15-d-old ethyroid rat brain supernatant (control) (tubulin 1.05 mg ml^{-1}); ●, 15-d-old hypothyroid rat brain supernatant (tubulin 0.95 mg ml^{-1}).



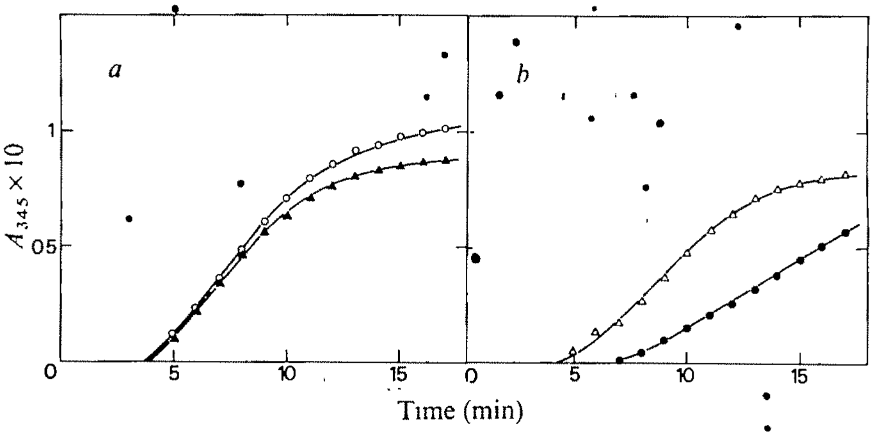


Fig. 2 Effect of thyroxine treatment on the turbidimetry time course of 15-d-old euthyroid and hypothyroid rat brain supernatants (obtained as described in Fig. 1). *a*, ○, 15-d-old euthyroid rat brain supernatant (tubulin 1.04 mg ml^{-1}); ▲, thyroxine-treated 15-d-old rat brain supernatant (tubulin 0.95 mg ml^{-1}). *b*, ●, 15-d-old hypothyroid rat brain supernatants (MTU treated (tubulin 0.95 mg ml^{-1})); △, thyroxine-treated 15-d-old hypothyroid rat brain supernatants (tubulin 1.04 mg ml^{-1}).

initiation process of microtubule assembly than on the tubulin content of the brain.

To test whether the observed low polymerisation was due to the lack of thyroid hormones or to a toxic effect of MTU, normal rats and animals rendered hypothyroid by MTU treatment were injected subcutaneously just after birth with 2 µg DL-thyroxine per day during 6 d and with 4 µg thyroxine per day during the last 9 d before killing. For the hypothyroid rats, thyroxine treatment produced a small increase in the tubulin concentration (MTU + thyroxine 4.04 mg tubulin per g wet weight). Figure 2 shows typical experiments where the effect of thyroxine treatment on the rate of *in vitro* microtubule assembly was studied with identical concentrations of tubulin in the assays and in the controls. Thyroxine treatment had no effect on the control (Fig. 2*a*), whereas the initial rate of assembly was markedly increased and the latency markedly reduced for the MTU-treated rat brain preparations (Fig. 2*b*).

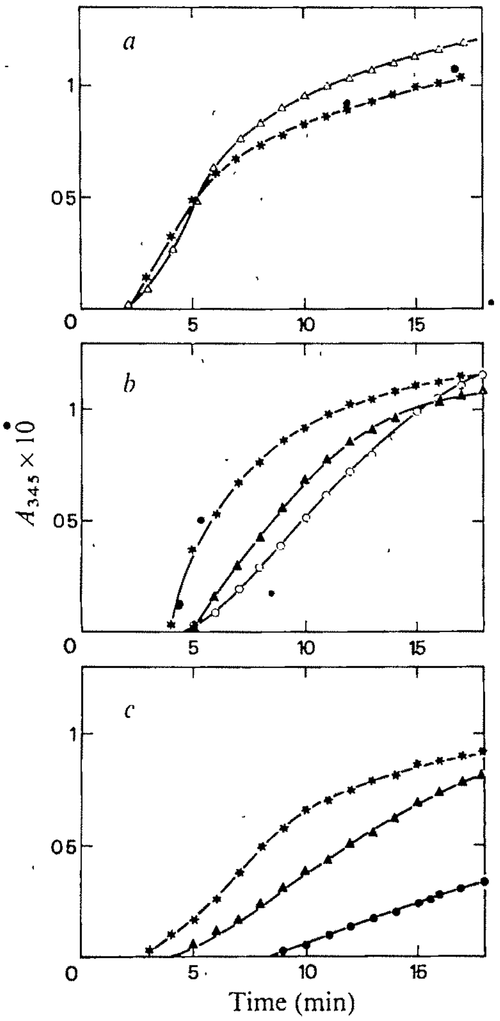

Fig. 3 Effect of τ factor on the turbidimetry (345 nm) time course at 37 °C of adult euthyroid, 15-d-old euthyroid and hypothyroid rat brain supernatants Experimental conditions were as described in Fig 1. τ factor was purified as before[17]. *a*, Adult rat brain supernatant (tubulin 0.88 mg ml^{-1}) in the absence (△) and in the presence (★) of τ factor (0.23 mg ml^{-1}). *b*, 15-d-old euthyroid rat brain supernatants (tubulin 0.78 mg ml^{-1}) in the absence (○) and in the presence of τ factor (▲, 0.115 mg ml^{-1}), (★, 0.23 mg ml^{-1}). *c*, 15-d-old hypothyroid rat brain supernatants (tubulin 0.73 mg ml^{-1}) in the absence (●) and in the presence of τ factor (▲, 0.115 mg ml^{-1}), (★, 0.23 mg ml^{-1}).

The effects of the addition of the τ factor, an initiator of microtubule assembly[18] were also studied. The τ factor was added in increasing amounts to 40- and 15-d-old brain supernatants prepared from euthyroid and hypothyroid rats (Fig. 3). The addition of the τ fraction to the adult supernatant did not produce an increase on the rate of assembly (Fig. 3*a*), suggesting that the adult brain supernatant contains saturating amounts of τ factor. In contrast, addition of τ factor to the 15-d-old brain supernatants produced an increase in rate of assembly (Fig. 3*b*). Thus 15 d after birth the τ factor concentration is still limiting. The effect of the τ fraction on the brain supernatants from MTU-treated rats was even greater; the initial rate of assembly increased to the level of the controls and the lag period decreased (Fig. 3*c*). Thus hypothyroidism probably produces a decrease in the concentration of the τ factor and not in the amount of tubulin. We reported before[18] that addition of a τ preparation significantly increased the rate of microtubule assembly of newly born (3-d-old) rat brain supernatants.

These observations suggest that microtubule formation during normal brain development requires the presence of thyroid hormones. If, as reported by others[20,21], microtubule assembly is required for axon growth and for the formation of nerve connections, the results of this work might contribute to the understanding of the effects of thyroid hormones in brain development and in the aetiology of cretinism.

Evidence from oxygen exchange measurements for a cooperative interaction between the two heads of myosin

THE present view of the molecular mechanism of muscle contraction[1] does not explain why myosin has two structurally similar globular heads[2]. Each of these heads can interact with actin and with ATP, and each seems to hydrolyse ATP at about the same rate[3]. To investigate possible functional differences between the two heads of myosin, we have compared the rates of intermediate oxygen exchange[4–6] catalysed by heavy meromyosin (HMM), which has two heads, and subfragment 1(S1), which has one head, at different levels of actin activation. This oxygen exchange occurs between water and the γ-phosphoryl groups of two enzyme–nucleoside phosphate intermediates along the pathway of coupled ATP hydrolysis[7]. Thus, measurements of oxygen exchange can be used to probe the kinetics of intermediate steps in the hydrolytic and contractile mechanism.

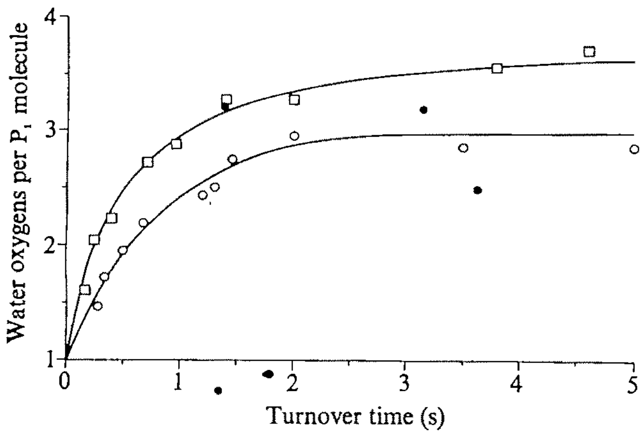

Fig. 1 Incorporation of ^{18}O from water into P_i as a function of turnover time. The assay mixture contained 25 mM KCl, 25 mM Tris buffer (*p*H 7.4), 5 mM $MgCl_2$, 5 mM ATP and appropriate concentrations of proteins in ^{18}O water at 23 °C. S1 was prepared from rabbit myosin by the method of Margossian *et al.*[12] with Mg^{2+} present instead of EDTA to preserve the DTNB light chain. HMM was prepared by the method of Holt and Lowey[13]. Actin was prepared from acetone-dried muscle powder by the method of Spudich *et al.*[14]. P_i was isolated as KH_2PO_4 essentially by the method of Dempsey *et al.*[15]. The ^{18}O content of P_i was determined by the method of Boyer and Bryan[16]. At each concentration of actin, the rate of hydrolysis was obtained from the slope of a linear rate curve and converted to a turnover number (molecules of ATP hydrolysed per second per active site). The turnover time on the abscissa is the reciprocal of this number. Actin markedly activated both fragments up to more than 100-fold at the highest levels. In the conditions of these experiments, with either fragment, the turnover rate increased linearly with the actin level; falling below the line only slightly at the highest level. To obtain a given average turnover time per head, about the same concentration of actin was needed with HMM as with S1. Turnover times were calculated using the equivalent weights of 120,000 per head for S1 (□) and 170,000 per head for HMM (○).

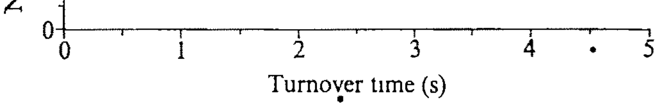

Fig. 2 Calculated number of exchange reactions as a function of turnover time. Conditions are given in Fig. 1 The number of exchange reactions was calculated using the equation of Wolcott and Boyer[8]

$$\frac{\text{water oxygens}}{P_i\text{ molecule}} = \sum_{n=1}^{n} (3/4)^{n-1}$$

where *n* is the number of exchange reactions. In each curve the initial slope, which extrapolates back to one exchange (the one added by the first cleavage of bound ATP) gives the average rate of exchange for the three exchangeable oxygens per P_i molecule. The upper shallow slope estimates the average rate of exchange after two oxygens per P_i molecule have been labelled, that is, when their exchange no longer has any significant or measurable effect on ^{18}O incorporation. Thus, the initial slope minus the final slope is the rate of exchange for two faster exchanging oxygens and the upper slope for one that exchanges slowly. ○, HMM; □, S1.

Any difference in the rate of oxygen exchange indicates either a difference in the lifetimes of the exchanging intermediates, or in the kinetic constants of the exchange reaction itself[4–6,8].

The results reported here show that HMM catalysed approximately half as much oxygen exchange per second per head as did S1. This indicates that in HMM there may be some cooperative interaction between the heads which effectively inhibits some part of the exchange mechanism. Since oxygen exchange is often correlated with the actin-activated ATP hydrolysis coupled to contraction[4–6,9] such an effect could reflect a cooperative action of the two heads in the generation of force or the regulation of contraction.

Actin decreases the turnover time of ATP hydrolysis by myosin and its fragments. It does this by activating the rate-limiting step in the hydrolytic pathway. This rate-limiting step follows oxygen exchange[1,7]. Therefore, the greater the actin concentration, the shorter the turnover time, and the shorter the lifetime of the exchanging intermediates. Figure 1 shows how the incorporation of ^{18}O from water into P_i changed when the turnover time was changed by the concentration of actin in the reaction solution. Figure 2 shows the calculated number of exchange reactions as a function of turnover time. The method for calculating the number of the reactions from the measured incorporation is given in Fig. 2. The slope of each curve in Fig. 2 gives an estimate for the average rate of oxygen exchange, that is, the number of exchanges per second of turnover time.

The use of such plots to study the kinetics of oxygen exchange is described in our recent paper[10]. From the earlier experiments with S1 (ref. 10) we concluded that the four oxygens in each γ-phosphoryl group do not all exchange at the same rate. To summarise our interpretation: the first oxygen is incorporated at virtually zero time by the very fast initial cleavage of the γ-phosphoryl group of bound

ATP (ref. 11); two oxygens exchange at a relatively fast rate by the mechanism of Bagshaw and Trentham[11], that is, by a cycle that first reverses the cleavage of the nucleotide and then recleaves it; each such cycle can cause the exchange of an oxygen atom, if the oxygens can rotate in space so that the one added by cleavage may be different from the one lost by reverse cleavage; the fourth oxygen exchanges very slowly, and this slow exchange indicates that one oxygen may be severely restricted from entering into the exchange cycle by its binding to the protein.

By comparing the slopes in Figs 1 and 2 it became evident to us that HMM, compared with S1, catalysed oxygen exchange at about half the rate per head. In general there are several alternatives for interpreting this finding but one that may have considerable significance to muscle contraction is the clear possibility that only one head of HMM at a time is in a conformation that can catalyse oxygen exchange. This would effectively reduce by half the measured rate of exchange per head. Such a cooperative effect that holds each head in a somewhat different conformation, that is, it does not allow them to take the same conformation at the same time, may coordinate the working of the two heads in the contraction and relaxation of muscle. Work is continuing with other fragments and other forms of S1 to test further whether the marked difference between the oxygen exchange rates of HMM and S1 heads reported here reflects a functionally important property of myosin.

Haemin protects Met-tRNA$_f$ binding activity of isolated reticulocyte ribosomes from inactivation by protein kinase

RETICULOCYTE lysates incubated in the absence of haemin stop synthesising proteins after a few minutes due to the accumulation of a translational inhibitor (TI) which blocks initiation of protein synthesis[1-3]. This block is characterised by a depletion of initiator tRNA (Met-tRNA$_f$) bound to 40S ribosomal subunits[4,5]. It has been reported that protein kinase activity is associated with TI which has been partially purified from reticulocyte lysates[6]. Addition of the initiation factor eIF-2 (previously designated IF-E2 or IF-MP), which binds Met-tRNA$_f$ and GTP, can overcome the block in initiation which develops in reticulocyte lysates incubated in the absence of haemin or with added TI[7,8]. Phosphorylation of eIF-2 by a protein kinase present in TI preparations has been demonstrated (refs 9–12 and P. Farrel, K. Balkow, R. Jackson and T. Hunt, personal communication), and it has been proposed that phosphorylated eIF-2 is inactive[8,9]. We have investigated the mechanism by which haemin stabilises initiation of protein synthesis by examining the ability of TI to inhibit binding of Met-tRNA$_f$ to ribosomes obtained from reticulocyte lysates supplemented with haemin or from unsupplemented lysates, and the corresponding pattern of ribosome-associated proteins phosphorylated by the protein kinase(s) present in the TI preparation. We have established a correlation between the phosphorylation of proteins associated with native 40S ribosomal subunits and the loss of binding activity of the ribosomes.

TI was prepared from unsupplemented reticulocyte lysates, as described before[6]. Protein synthesis by reticulocyte lysates supplemented with 50 μM haemin is inhibited 80% by 25 μg of TI preparation in a 50-μl assay (unpublished work of Sarma, M. and Baglioni, C.). Ribosomes isolated from reticulocyte lysates (Fig. 1) were incubated with (^{3}H)Met-tRNA$_f$ and GTP. The amount of initiator tRNA bound was measured by passing the incubation mixture through nitrocellulose filters directly or by fractionating the incubation mixture on gradients[13]. Gradient fractions were passed through filters, and Met-tRNA$_f$ was found bound to ribosomes only (data not shown). This binding is GTP dependent and eIF-2 is the only initiation factor reported to bind Met-tRNA$_f$ in a GTP-dependent fashion[14].

Inhibition of Met-tRNA$_f$ binding by TI was assayed by

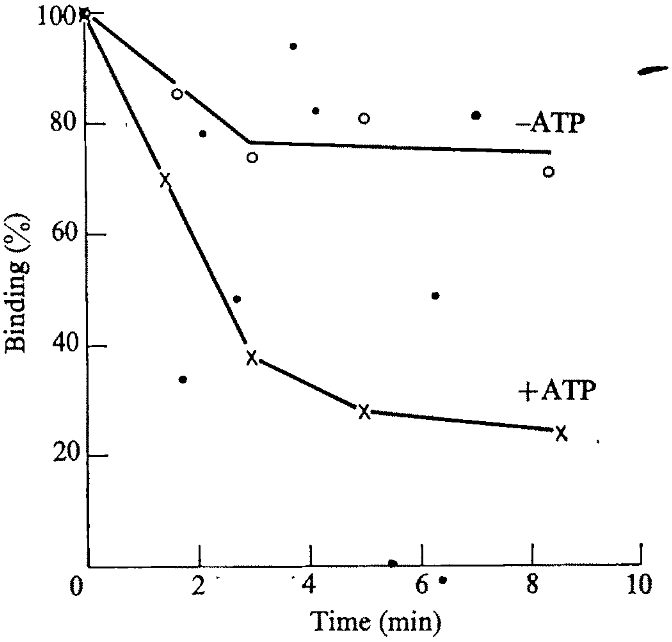

Fig. 1 Time course of inhibition of (^{3}H)Met-tRNA$_f$ binding to ribosomes by a translational inhibitor (TI) in the presence or absence of ATP Reticulocytes were obtained from rabbits made anaemic with 1-acetyl-2-phenylhydrazine. TI was prepared from the postribosomal supernatant of unincubated reticulocyte lysates, following the procedure of Levin *et al.*[6]. The fraction eluted from DEAE-cellulose at 0.24 M KCl was used. Ribosomes were prepared as previously described[14], except that all solutions contained 1 mM dithiothreitol. Stripped Met-tRNA$_f$ from rabbit liver (Grand Island Biological Co.) was charged with (^{3}H) methionine (3.7 Ci mmol^{-1}) using an *E. coli* aminoacyl synthetase (Miles). Approximately 40 μg of ribosomes were incubated in 35μl incubation mixtures containing buffer A (110 mM KCl, 20 mM Tris-HCl *p*H 7.5, 5 mM MgCl$_2$, 1.2 mM dithiothreitol), 12 μg of TI and 40 μM ATP (×) or no ATP (○). After incubation at 30 °C for the time indicated on the absissa 3 pmol of (^{3}H)Met-tRNA$_f$ (7,500 c.p.m.) and 1 mM GTP in 15 μl of buffer A were added and the incubation continued for 5 min at 24 °C. The reactions were stopped and the (^{3}H)Met-tRNA$_f$ bound determined by the nitrocellulose filter assay previously described[14] Samples which were not incubated at 30 °C before the addition of Met-tRNA$_f$ bind about 0.3 pmol of Met-tRNA$_f$. Binding is expressed as the percentage of binding activity relative to such samples.

pre-incubating ribosomes with TI for various times, then adding Met-tRNA$_f$ and GTP (Fig. 1). Only some loss of binding activity is observed on incubation of ribosomes with ATP or TI (Table 1). Addition of 40 μM ATP together with 12 μg of TI however, results in 75% inhibition of the binding of Met-tRNA$_f$ (Fig. 1). We have, therefore, shown an ATP requirement for the inhibition, suggesting that the protein kinase activity of TI is directly responsible for the inhibition of Met-tRNA$_f$ binding to ribosomes in the assay described. The ATP requirement can be shown because ribosomes have been isolated through a sucrose cushion, thus removing endogenous ATP. Incomplete removal of ATP may be responsible for the slight loss of Met-tRNA$_f$ binding activity observed in incubations with no added ATP (Table 1). Addition of 1.5 μM cAMP has no effect on the loss of Met-tRNA$_f$ binding activity (data not shown), indicating that the inhibitor protein kinase is not stimulated by cyclic AMP.

Inhibition of Met-tRNA$_f$ binding by TI and 40 μM ATP is incomplete, leaving about 25% of the original activity of control ribosomes (Fig. 1). This residual binding may be due to eIF-2 activity which is resistant to inactivation by TI A higher resistance to inactivation by TI is indeed observed with ribosomes prepared from lysates supplemented with haemin (Fig. 2). Loss of Met-tRNA$_f$ binding activity is consistently less for these ribosomes than for ribosomes prepared from unsupplemented lysates (Table 1).

Since inactivation of Met-tRNA$_f$ binding in the presence of TI is ATP-dependent and protein kinase activity is present in TI preparations, it is reasonable to propose that specific initiation factor(s) involved in the binding of initiator tRNA to ribosomes are inactivated by phosphorylation. We have, therefore, used (^{32}P-γ)ATP to phosphorylate reticulocyte ribosomal proteins and have examined the proteins by electrophoresis on polyacrylamide gels. Figure 3 shows the autoradiographic pattern obtained when ribosomes are incubated with TI in conditions which lead to the inhibition of Met-tRNA$_f$ binding (track 1). Many of the bands correspond to polypeptides present in the TI preparation (track 5). Notable among the phosphorylated polypeptides of ribosomes (track 1) are those of MW 67,000, 53,000 and 38,000. The 67,000 polypeptide has a MW similar to that of initiation factor IF-M1, which has been reported to be 65,000 (ref. 15). The other bands may correspond to two of the three polypeptides comprising eIF-2.

Table 1 ATP dependence of the inhibition of Met-tRNA$_f$ binding by a translational inhibitor (TI) and protection from inactivation by haemin

Exp. no.	Inhibition (%) +ATP	 +TI	 +TI +ATP	 +TI +ATP +haemin
1	21	19	71	43
2	30	—	73	51
3	24	—	78	—
4	—	11	54	—
5	—	9	64	—
6	—	—	61	50

Ribosomes were incubated 5 min at 30 °C with 40μM ATP, where indicated, and/or 12 μg TI, and then with (^{3}H)Met-tRNA$_f$ and GTP as indicated in Fig 1. Determination of the bound Met-tRNA$_f$ was as described in the legend of Fig. 1. Ribosomes from the incubations designated as '+haemin' were obtained from reticulocyte lysates supplemented with 50μM haemin, all other incubations contained ribosomes from unsupplemented lysates. Inhibition is expressed as the percentage of binding activity lost relative to samples not incubated at 30 °C before addition of Met-tRNA$_f$ and GTP. Different preparations of ribosomes obtained from different lysates were used for each experiment. Addition of TI and ATP after incubation of ribosomes with Met-tRNA$_f$ and GTP does not decrease the amount of bound Met-tRNA$_f$. Protein synthesis in cell lysates is 50% inhibited by 10μg of TI in a 50-μl assay[13], and Met-tRNA$_f$ binding is inhibited 50% by 5 μg of TI in the assay described in the legend of Fig. 1.

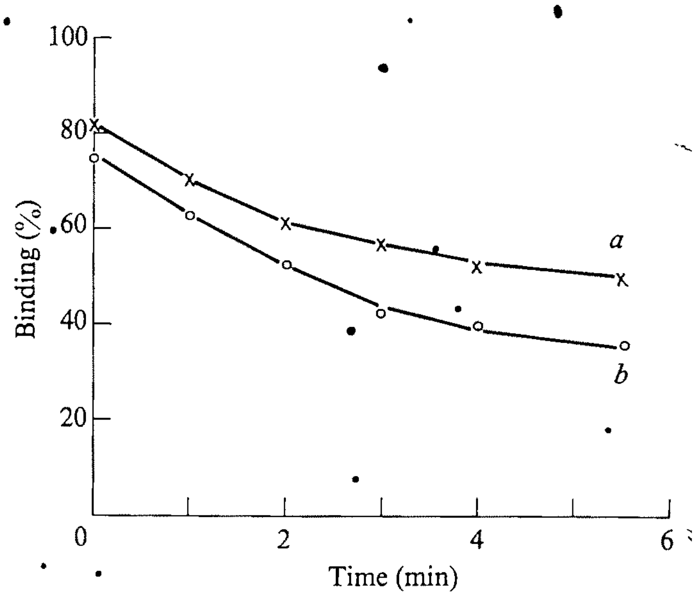

Fig. 2 Time course of haemin protection of (^{3}H)Met-tRNA$_f$ binding to ribosomes from inactivation by TI. Approximately 40μg of reticulocyte ribosomes from either lysates supplemented with 50 μM haemin (*a*) or unsupplemented lysates (*b*) were incubated with 40 μM ATP and TI at 30 °C for the time indicated on the absissa as described in Fig. 1 Then (^{3}H)Met-tRNA$_f$ and GTP were added, the incubation continued at 24 °C for 5 min, and the samples processed as described in Fig. 1. Binding is expressed as a percentage of the amount of (^{3}H)Met-tRNA$_f$ bound relative to samples incubated without TI.

Phosphorylation *in vitro* of each of the three subunits of eIF-2 by protein kinases has been reported (refs 9–12, and P. Farrel *et al.*, personal communication). Moreover, phosphorylation of the 38,000 subunit may be responsible for inhibition of initiation of protein synthesis (ref. 11, and P. Farrel *et al.*, personal communication). Phosphorylation of other initiation factors which stabilise the association of Met-tRNA$_f$ with 40S ribosomal subunits[16] may also play a role in the inhibition of Met-tRNA$_f$ binding.

A difference in the pattern of phosphorylated polypeptides is observed between ribosomes prepared from lysates supplemented with haemin (track 2) and those from unsupplemented lysates (track 1). A polypeptide of MW 53,000 is phosphorylated to a much greater extent in the ribosomes from unsupplemented lysates. This polypeptide is associated with native 40S ribosomal subunits. Incubation of these subunits with TI and (^{32}P-γ)ATP results in the phosphorylation of several polypeptides, among which is the 53,000 polypeptide. Addition of 50 μM haemin to the incubation medium markedly decreases the phosphorylation of this polypeptide (Fig. 3, tracks 3 and 4). The 53,000 MW polypeptide is not associated with salt-washed 40S subunits derived from polysomes (unpublished work of Sarma, M. and Baglioni, C.). Since most eukaryotic initiation factors are associated with native 40S ribosomal sub-units[17,18], it is likely that the polypeptides phosphorylated by TI which are associated with these subunits, but not with salt-washed 40S ribosomal subunits, are initiation factors.

The data presented here show that a certain amount of the Met-tRNA$_f$ binding capacity of ribosomes is resistant to inactivation by TI. Ribosomes from haemin-supplemented lysates show a greater resistance to inactivation by TI than those from unsupplemented lysates. This increased resistance due to haemin is correlated with a decrease in phosphorylation of a specific polypeptide of MW 53,000.

We have established that haemin co-sediments with ribosomes prepared from cell extracts supplemented with 50 μM haemin. By analysing the visible absorption spectrum of these ribosomes, we find the typical spectrum of a haemin–protein complex with a maximum absorption at 390 nm.

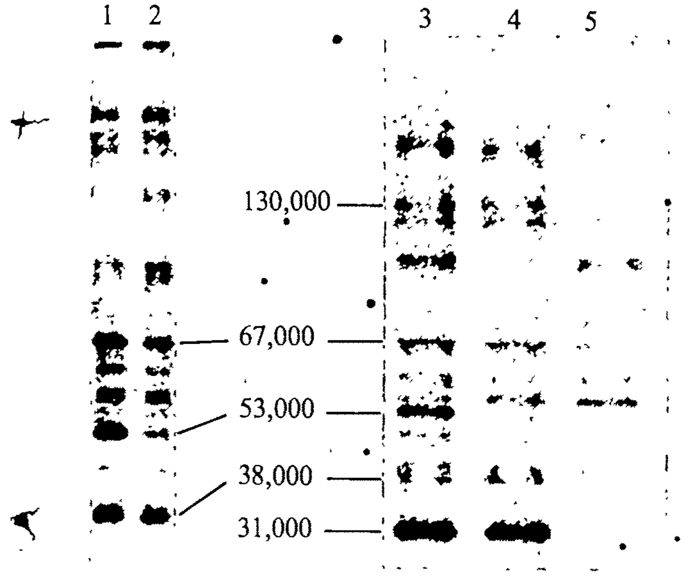

Fig. 3 Polyacrylamide gel electrophoresis of (^{32}P)-labelled ribosomal proteins. For tracks 1 and 2, 40 μg of ribosomes from either lysates supplemented with 50 μM haemin (2) or unsupplemented lysates (1) were incubated with TI as described in Fig. 1, except that 40 μM (^{32}P-γ)ATP (15 Ci mmol^{-1}) and 1.5 μM cyclic AMP but no (^{3}H)Met-tRNA$_f$ or GTP were added. Omission of cyclic AMP results in no change in the pattern of phosphorylated proteins at this ATP concentration. For tracks 3, 4 and 5, 25 μg of TI were incubated with 30 μg of BSA, 400 μM ATP, 5 μCi of (^{32}P-γ)ATP, 1.5 μM cyclic AMP, 25 mM HEPES-KOH (*p*H 7.2), 6 mM Mg(OAc)$_2$, 20 mM KCl, and the following additions: 3, 16 μg of native 40S ribosomal subunits prepared according to Freienstein and Blobel[18]; 4, 16 μg of native 40S subunits and 50 μM haemin; 5, no additions. Incubations were at 30 °C for 30 min in a 50-μl volume. Omission of cyclic AMP resulted in a significant decrease in the phosphorylation of only two bands, one of MW 31,000 which is a ribosomal protein present in salt-washed 40S ribosomal subunits[12] and the other of approximate MW 130,000. Reactions were stopped by adding an equal volume of 2× electrophoresis buffer. Samples were fractionated by electrophoresis on 8-cm gel slabs, made with 12.5% acrylamide and 0.1% *bis*-acrylamide at *p*H 8.7, with a 2-cm, 5% acrylamide, 0.13% *bis*-acrylamide stacking gel at *p*H 6.8 according to Laemmli[21] with *bis*-acrylamide concentrations from Blattler *et al.*[22]. Electrophoresis was at room temperature for 1 h at 50 V, then for 3.5 h at 150 V. Gels were stained with Coomassie Brilliant Blue, dried, and autoradiographed for 1–3 days using Kodak RP Royal X-Omat film. The MW included have been calculated by running in separate tracks marker polypeptides of known MW.

Ribosomes obtained from cell extracts unsupplemented with haemin do not show such an absorption at 390 nm. Haemin may (i) render the 53,000 MW polypeptide a less accessible substrate for a protein kinase, (ii) increase the activity of a phosphatase specific for this polypeptide, or (iii) inhibit a kinase which specifically phosphorylates this polypeptide Haemin may modulate the activity of a protein kinase and of a phosphatase, as suggested by Traugh[19]. The finding that haemin promotes the aggregation of inactive low MW initiation factors into active high MW complexes[20], suggests, however, that haemin may directly change the conformation of initiation factors and possibly render them more resistant to inactivation by protein kinases.

Does 5S RNA function by a switch between two secondary structures?

THE structure of 5S RNA has been a lively field for experiment and speculation, with no definitive resolution of the problem in sight (see refs 1 and 2 for reviews). Fox and Woese[3] suggested comparative sequence analysis of prokaryotic 5S RNAs as a method for locating base paired regions, an appealing procedure because of its similarity to the method used to substantiate the cloverleaf model for tRNA. Its logic states that if all known 5S RNA sequences contain complementary bases at a site, a double helix probably exists there in the functional form. We propose that comparative sequence analysis suggests two different functional structures for prokaryotic 5S RNA. One of them has been introduced by Fox and Woese[3], and its secondary structure is based on four conserved helices: the 'molecular stalk' (*Escherichia coli* residues 1–10 and 119–110), the weak 'tuned helix' (18–23/65–60), the 'common arm base' (31–34/51–48) and the 'prokaryotic loop' (82-86/94-90). The base paired structure that results is consistent with enzymatic digestion[14] and chemical modification[1,5] results on native 5S RNA, if allowance is made for protection of residues by tertiary bonding as well as secondary structure. This 'model', however, does not explain the apparent conservation of a double helix (33–39/88–82 in *E. coli*) (Table 1) which is sterically inconsistent with two of the helices listed (the common arm base and the prokaryotic loop). Fox and Woese[3] noted this conservation but considered it unimportant because of the variable helix length and the conflict with the other two helices.

Our proposal begins with the observation that the alternate conserved helix explains the enzymatic degradation pattern[4] of the 'denatured' or B form of 5S RNA (ref. 13), whereas the Fox and Woese model does not. Hence the alternate conserved helix, which we term the 'central helix', may be part of the secondary structure of the B form. Since the central helix is conserved over all known sequences, we conclude that it is functionally significant. Therefore the finding of two conformational forms of 5S RNA is neither accident nor artefact, but an indication of an important conformational balance which allows rearrangement of 5S RNA secondary structure during protein biosynthesis. The fact that only the A form has yet been isolated from native ribosomes may be because of instability of the B form except in the elongation factor G/GTP/ribosome complex.

Figure 1 shows the two models. The crucial observations that distinguish them derive from the nuclease digestion experiments of Jordan[4]. He found a fragment of the B form containing residues 25–41 and 96–80, clearly indicating that those

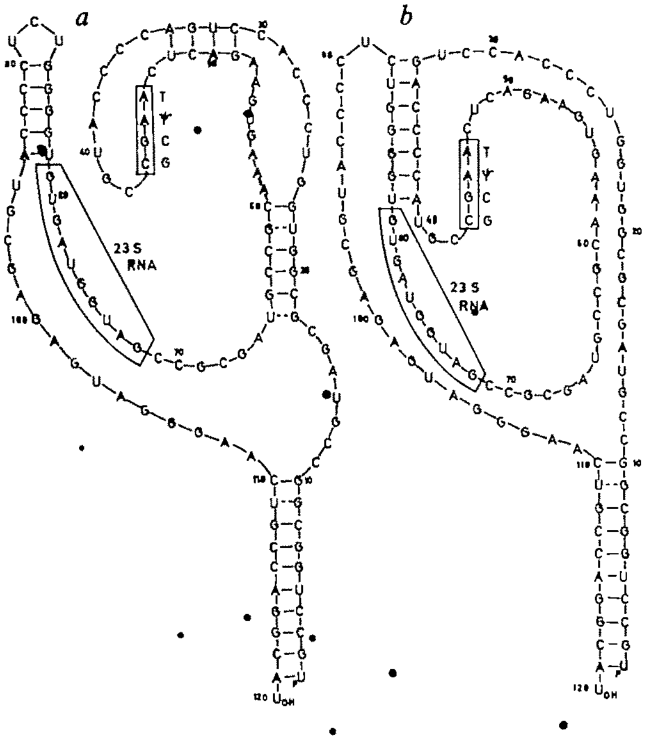
sections are bonded together. This feature is found in our B-form model but not in the A-form model. The only double helices included in Fig. 1 are those which can be justified by comparative sequence analysis. The 'tuned helix', though sterically feasible in the B form, is not included because chemical modification results[5] indicate that G_{61} is accessible for modification in the B form. The high activation energy necessary for the conversion between the two forms[14] corresponds well to the melting of the specific helices.

We feel that most of the remaining structural organisation of both 5S RNA forms is probably not provided by Watson–Crick base pairing, but rather by tertiary interactions of an unknown nature. There is, however, no definitive method for distinguishing secondary and tertiary structures in RNA molecules. NMR measurement of protons in base pairs is a promising technique, but is complicated by the contribution of resonances from protons in tertiary bonds with chemical shifts similar to protons in standard base pairs[15–17]. Hence we can discount detailed models of 5S RNA structure based on NMR measurements which ignore possible contributions from tertiary bonds[18]. Our studies of conformational equilibria and dynamics in 5S RNA (in preparation) provide circumstantial evidence favouring extensive tertiary structure in 5S RNA.

Fig. 1 *a*, A-form snd *b*, B-form conformations of prokaryotic 5S RNA. Sequences complementing 23S RNA and tRNA segments are indicated.



The detailed mechanism of the 5S RNA conformational switch, and the role of GTP hydrolysis and ribosomal proteins[19,20], are subjects for potentially endless speculation. We limit ourselves to one observation. Figure 1 shows the highly conserved region G_{71}–G_{83}, which has recently been found to be complementary to a 23S RNA sequence[21]; also nucleotides CGAA in position 43–46 have been proposed[22,23] as a tRNA binding site on the basis of their complementarity with the tRNA sequence TΨCG. Note that the first base of the central helix precedes this CGAA sequence by exactly 10 nucleotides in all species but the blue-green alga *Aspergillus nidulans*, where both helix and distance are shorter by one nucleotide. The A $\rightleftharpoons$ B conformational switch, as represented in Fig. 1, places the tRNA binding site adjacent to the 23S RNA in the B form, but free to move away from that position in the A form. A switch from one conformation to another, possibly induced by the binding and release of the elongation factor G, could cause movement of the tRNA relative to the 23S RNA. As the migration of the mRNA in the ribosome is probably induced by the tRNA (ref. 24), a process of this sort is likely to be part of the translocation step in protein biosynthesis.

matters arising

Assortative mating

VETTA[1] claims that Fisher's[2] well known formulae for the correlations between relatives under assortative mating are incorrect, and he presents alternative formulae for the parent–child and sib–sib correlations. I intend to publish elsewhere a simplified proof of Fisher's results, but it seems worthwhile to indicate here why I am not convinced by Vetta's argument.

Consider for simplicity the case in which there is no dominance and no environmental variability, so that all the variance is additive genetic. The alternative formulae for the parent–child correlation, which is in this case the same as the sib–sib correlation, are as follows

$$\text{Fisher: } \tfrac{1}{2}(1+\mu)\text{, and}$$
$$\text{Vetta: } \tfrac{1}{2}[1+\mu(1-\mu)^2]$$

where μ is the correlation between husband and wife. There is nothing in Fisher's model which restricts attention to positive, as opposed to negative, assortative mating, so that μ may meaningfully take any value between −1 and +1. Fisher's correlation increases linearly from 0 to 1 as μ increases from −1 to +1, which seems reasonable. Vetta's correlation is negative when $\mu < -0.47$, which seems implausible, and is less than −1 when $\mu < -0.87$, which is impossible. Even if we confine our attention to positive values of μ the behaviour of Vetta's correlation is strange, since it increases from 0.5 to 0.574 as μ increases from 0 to $\tfrac{1}{3}$, and then decreases back to 0.5 as μ increases further from $\tfrac{1}{3}$ to 1; I find it difficult to understand how the correlation can fail to be an increasing function of μ.

It is also quite easy to prove, at least to my satisfaction, that Fisher's correlation is correct in this case. Elementary genetic considerations show that the expected value for the child given full information about the complete genotypes of both parents is equal to the mid-parental value. Hence the regression of child on mid-parent is linear with unit slope, from which it follows that the parent–child correlation is $\tfrac{1}{2}(1+\mu)$.

Vetta claims that Fisher's formulae cannot be true in general because they predict that the parent–child correlation will in some circumstances exceed the sib–sib correlation; Vetta considers this to be impossible, but has given no reason to support this assertion.

I conclude that Vetta has failed to demonstrate that Fisher's formulae are incorrect, and that the alternative formulae presented without proof in his paper are almost certainly incorrect.

M. G. BULMER

Department of Biomathematics,
University of Oxford,
Pusey Street, Oxford, UK

[1] Vetta, A *Nature* 263, 316–317 (1976).
[2] Fisher, R A *Trans. R. Soc Edinb* 52, 399–433 (1918)

VETTA REPLIES—I consider[1] that the assumptions on which Fisher[2] derived his formulae are not valid for his model and Bulmer[3] raises no objection to this. His objections concern the parent–child correlations not being a linear function of μ, the applicability of the model to disassortative mating and the excess of sib correlation over parent–child correlation. I consider these in turn.

Bulmer[3] claims that there is nothing in Fisher's model which restricts μ and that it "may meaningfully take any value between −1 and +1". Unfortunately, the constraints of Fisher's model are not well understood. In fact, A (= μ in Bulmer's example) cannot be increased to 1 without limit. For example, when $A \simeq 1$, the increase in additive variance is infinitely large. It is difficult to conceive of any trait with infinite variance. That assortative mating could increase genetic variance to infinity is beyond belief. It is more likely that there are genetic constraints which ensure that the increase in variance brought about by a given degree of assortative mating will not be too large. The notion that A can be increased at will, to 1, is unacceptable.

Is there any reason, apart from the formula $\tfrac{1}{2}c_1c_2(1+\mu)$, to assume that the parent–child correlation will increase linearly with μ? I know of none. Indeed, it is not absolutely clear how a non-linear increase, $A\tau^2/(1-A)$ in the additive variance should give rise to a linear increase of exactly $\tfrac{1}{2}A$ in the parent–child correlation. There is, therefore, no reason to believe that A can take any value between 0 and 1 and that the increase in the parent–child correlation should be exactly $\tfrac{1}{2}A$.

Are there any data which might indicate that an increase in μ will, necessarily, result in an increase in the parent–child correlation? Data on human populations are scarce but studies[4] on racehorses, which have been bred assortatively for generations, do not support this assertion.

Fisher[2] showed that assortative mating (AM) will introduce association between phases of factors of an individual and this will increase the additive variance of the population. Wright[5] asserted that AM will also introduce correlation between the additive and dominance deviations of mates. I show that this, indeed, happens in Fisher's model. Fisher, however, did not take acccount of such correlations. In deriving my formulae, I take account of these and thus, provide a synthesis of Fisher and Wright on AM. I show that AM will (1) increase the association between additive deviations of a parent and his progeny and (2) introduce association between the additive deviations of one and the dominance deviations of the other. These considerations require a correction term to Fisher's formulae. This term, when $c_1 = c_2 = 1$, will be $\tfrac{1}{2}A^2(A-2)$ for parent–child correlation. Note that when $c_2 = 1$,(2) is 0 but (1) is not 0.

In Fisher's model A has two meanings: it is the genetic component of μ and it also represents genetic correlation between phases of factors. It occurs in the former sense in Fisher's formulae and in the latter sense in my correction term. Obviously, when the correlation between phases of factors is 0, that is, the population is mating assortatively for the first time, my correction term is 0. I, therefore, assert that Fisher's formula for parent–child correlation, as given by Bulmer, is correct for a population which mates assortatively for the first time and is not correct for his model where the population is in equilibrium under a given degree of AM.

Geneticists[6,7] distinguish between assortative and disassortative mating because they have different genetical consequences. No polygenic model of disassortative mating is available. If one is constructed on the lines of Fisher's model. it will differ from the latter in three respects. First, there will be negative correlation between genotypes of an individual. Second, the genetic variance will decrease. And third, the correlation between the additive and dominance deviations of mates will be negative. Moreover, the attainment of equilibrium may present certain problems. Even if, for a given μ, all these effects were exactly the same in the two models, the correlational formulae may still not be the same. Fisher[2] restricts himself to a model which results in "an increase in variance". Later[8,9] discussing it, he uses assortative mating and homogamy by which he means "the tendency of mating like with like" interchangeably.

I considered the possibility that, for his model, sib correction could be greater than the parent–child correlation but rejected it. Briefly, the reason is that, in presence of partial dominance, it is greater than parent–child correlation for one factor as well as for a large number of factors[10]. This holds for assortative mating when the number of factors is small. There is no reason to believe that the situation is reversed when the number of factors is large. Fisher[2,9], himself, believed this to be the case for his model and I agree with him. For, in Fisher's model, where add., dev., dom. and cov. stand for additive, deviation, dominance and covariance respectively, sib covariance = cov.(add. dev., add. dev.) + cov.(add. dev., dom. dev.) + cov.(dom. dev., dom. dev.), and parent–child covariance = cov.(add. dev., add. dev.) + cov.(add. dev., dom. dev.). All covariances on the right of these equations are positive. Mendelian segregation will ensure that cov.(add. dev., add. dev.) and cov.(add. dev., dom. dev.) in the two equations are equal. It is obvious that in presence of dominance, sib covariance will be greater than the parent–child covariance. In absence of dominance they will be equal. Incidentally, I do not assert that it is 'impossible' for parent–child correlation to exceed the sib correlation, only that, in Fisher's model, it should not.

Cholecystokinin produces bait shyness in rats

BECAUSE an injection of cholecystokinin (CCK) (or of the synthetic C-terminal octapeptide of CCK[1]) reduces food intake in the fasted rat, it has been suggested by Gibbs, Smith and colleagues[2–6] that CCK may be a satiety signal. We present here evidence against this conclusion.

To quote from ref 4, "In order to establish CCK as a physiological satiety signal, one requirement is that CCK does not inhibit feeding by inducing nausea or other subclinical sickness". An attempt to detect such sickness was made by injecting CCK after the rats had drunk a saccharin solution. If sickness occurs after CCK then less of the saccharin solution should be drunk on a subsequent occasion[7,8].

The tests for nausea already performed[2,3], however, were quite insensitive. In the first[2] the rats were extremely thirsty (23½ h) and were given a very attractive sweet taste to drink (0.25% saccharin). Such test conditions would only be expected to reveal a very strong nausea induced by CCK. The dose of CCK used in this nausea test suppressed eating by only 50% when the CCK was injected before the rat ate[2]. This suggests that only a mild degree of nausea was induced by that dose of CCK if nausea was indeed the explanation. The results of the test showed no effect of CCK (40 U kg^{-1}) or synthetic terminal octapeptide of CCK (40 U kg^{-1}) but a strong effect of 0.15 M lithium chloride as 0.6% body weight. Lithium chloride in this dosage is a very powerful aversive agent. Even higher levels of thirst were used in a comparison of apomorphine, another strong aversive agent, with CCK (40 U kg^{-1}) (ref. 4). Conditioned aversion was shown to apomorphine but not to CCK. Whilst these studies show that in the doses used, CCK (or the C-terminal octapeptide) is less aversive than LiCl or apomorphine, more sensitive tests of nausea might reveal intermediate degrees of aversiveness.

In our first experiment we used rats (Charles River, male Sprague–Dawley) 22-h thirsty and given 8-min exposure to a novel neutral flavour (almond Schilling 0.5% in water). Immediately after this drinking period nine rats were injected intraperitoneally with 40 Ivy dog units per kg of the terminal octapeptide in saline[6], and 8 h later the rats were given water *ad libitum* for 2 d. Then they were again water deprived for 22 h. Both groups were then again presented with the almond solution for 8 min. The mean amount consumed on the first day of exposure was almost identical for the experimental rats (10.3 ml) and for the control rats (10.4 ml), but on the second presentation the control rats drank a mean of 14 ml as against 9.6 ml consumed by experimental animals ($t=3.66$, d.f.$=16$, $P<0.01$). We used an even more sensitive indicator of conditioned aversion in our second experiment by using a preference instead of a single bottle method as a test. A group of 14 naive Sprague–Dawley rats underwent 22 h water deprivation; half the rats were then presented with almond flavoured water and the others with banana flavoured water (both 0.5% Schilling). After 24 h of water *ad libitum* the rats were again deprived of water for 22 h and allowed to drink the alternate flavour. Immediately following the consumption of this flavour, the experimental rats were injected with CCK octapeptide as above, while the control rats were injected with vehicle. After 24 h of water *ad libitum*, rats were again fluid deprived for 22 h. They were then given a 30-min simultaneous choice between the two flavoured solutions. The controls drank a mean of 8.9 ml of the flavour presented on the first day, and a mean of 8.6 ml of the fluid presented on the second day when these fluids were simultaneously presented. In contrast, the rats injected with the CCK C terminal octapeptide drank a mean of 9.4 ml of the flavour that had been presented on the first day, but only a mean of 3.3 ml of the flavour paired with the octapeptide when the two flavours were presented simultaneously. There was a significant difference between the experimental and control groups ($t=4.36$, d.f.$=12$, $P<0.001$), indicating a larger conditioned aversion due to the octapeptide measured by this more sensitive method. We therefore conclude that the C terminal octapeptide of CCK in the dose administered to produce apparent satiation causes some form of sickness in the rat. Whether CCK is a satiation hormone is therefore left in considerable doubt.

We thank Dr A. Ondetti, Squibb Institute for Medical Research, for CCK octapeptide.

GIBBS AND SMITH REPLY—The production of a conditioned taste aversion, using a single dose of the synthetic octapeptide of CCK as the unconditioned stimulus, is not a critical test of the hypothesis that CCK mediates all or part of the satiety effect of food in the intestine. One indirect test of the hypothesis using the taste aversion paradigm would be the comparison of dose–response curves for both satiety and taste aversion If the doses of CCK required for satiety were always equal to or larger than the doses that are aversive enough to produce a conditioned taste aversion, this would be indirect evidence against the hypothesis. Such a comparison has not been performed. The hypothesis will be most critical tested, however, when the concentration of circulating, endogenous CCK can be measured reliably during satiety. Then it should be possible to decide if ingested food releases sufficient CCK to account for the satiating effect of that ingested food.

Landscape legacy for Ireland

R. Common

The Irish Landscape. By F. Mitchell. Pp.240+32 plates. (Collins: London, 1976.) £5.50.

As an environmental scientist, and as a countryman at heart, Professor Mitchell is concerned in this book with the interactions of natural phenomena and the relationships between man and environment that are now reflected in the Irish landscape.

The author first provides an outline of the geological evolution of Ireland, emphasising the broad relationships between rock type, rock structure and denudation process in the disposition of the major relief features Professor Mitchell embellishes his narrative, from the outset, with comments that are definitive or with opinions that are open ended. He uses the map appropriately, to show space relationships, and the diagram effectively, to indicate the time sequences of formative events.

Explanatory descriptions of selected features that are associated with near-glacial and glacial conditions introduce the next chapter, which is concerned with palaeogeographical conditions in the Quaternary era. The author provides an interpretation which enlightens rather than confuses, and resists the temptation to depart from valuable generalisation for the complexities of local detail. His subsequent treatment of the development of Irish soils, plant covers and animal populations as climatic conditions, land and sea distributions changed in post-glacial time is equally thoughtful and disciplined.

Chapter 4 deals with the first farmers and their growing influence on the physical environment over a timespan of almost 4,000 yr. The findings of the archaeologist and the palaeobotanist provide the basis for the author's suggested sequence of landscape changes Amendments, no doubt, will follow as more evidence becomes available, but these should not diminish the importance of this particular contribution or the diligent research work of fellow scholars

In dealing with the landscape from early mediaeval times to 1900 the author reinterprets historical events in terms of human activities on the land. The human errors and pressures which encouraged environmental deterioration in this period seem to have influenced his thoughts on present conditions. Chapter 6, in fact, begins with a review of significant features in the contemporary scene and then considers the options for change which can enrich or degrade them. Understandably, therefore, the final chapter develops this important theme of a landscape legacy which future generations of Irish people will inherit.

This well illustrated book is written with a direct style, a clarity of thought and a turn of phrase which make for pleasurable reading. It will appeal to those with general interests in Natural History besides satisfying those with particular interests in Ireland. In academic terms it claims a significant place beside the writings of R. L. Praeger, J. K. Charlesworth and E. E. Evans. ☐

R. Common is Reader in Geography at Queen's University, Belfast, Northern Ireland.

Pheromone communication

Animal Communications by Pheromones. By H. H. Shorey. Pp viii+167 (Academic: New York and London, 1976) $16.50; £10.05.

PHEROMONES are chemicals produced by an individual which elicit specific behavioural or developmental reactions when perceived by other individuals of the same species. The presence of pheromones has been deduced in most animals, from Protozoa to primates, and in some groups, such as the insects and mammals, many pheromones have been identified chemically, and the synthetic compounds shown to have the same effects as the natural substances.

A comprehensive survey of the functions of pheromones requires a formidable knowledge of the morphology, physiology, behaviour, and even ecology, of members of almost every animal phylum The author of *Animal Communication by Pheromones* points out that no single-authored monograph on pheromones has hitherto been published, and that his book is an attempt to review, digest and present in a cohesive manner pheromone communication within the entire animal kingdom. Unfortunately, the book falls far short of these objectives.

Only brief mention is made of 'primer' pheromones, a surprising omission, since the ways in which these substances induce developmental changes in the recipients can usefully be compared in animals as diverse as the insects and the mammals, and discussion of those pheromones which induce both behavioural and developmental changes must necessarily also be limited. The arrangement of chapters dealing with particular 'classes' of pheromones—recognition, aggregation, dispersion, and so on, inevitably leads to repetition. The author's style is turgid and often leads to confusion. For example, what is one to make of: "Colonization begins with the alightment on a suitable host tree of an initially invading beetle, which may be a male or female (*but not both*), depending on the species" (p56) (my italics).

Many of the line drawings are unnecessary, and most of the plates are too dark and without contrast. Figure 14 (courtesy of N. W. Nowell) has a hopelessly inadequate legend, and must be meaningless to all but Dr Nowell, even with reference to the text And why did the publishers decide to begin each chapter on an odd-numbered page? This may be useful in multi-authored compendia, where each contributor is normally given a number of reprints, but in the present volume it results in some chapters ending with up to one and three quarters blank pages. Since £10.05 buys only 121 numbered text pages, these blank spaces are expensive. The book contains an extensive bibliography of 726 titles, together with taxonomic and subject indexes. It cannot be recommended.

Plants and pathogens

Plant Pathosystems. R A. Robinson. Pp. x+184 (Springer: Berlin, Heidelberg and New York, 1976.) DM48; \$19 70

MR ROBINSON is a plant pathologist who has been much involved over many years in breeding crop plants for resistance to important pathogens in a number of developing countries. It is therefore not surprising when he states in his preface that this book was written in remote places far from good library facilities. This being so, one asks what would have been the difference had this been otherwise, because *Plant Pathosystems* is already a very good book and unique in many ways. The text is based on long and varied experience of field plant pathology in Africa and essentially is a series of perceptive analyses of interactions between populations of host plants and populations of pathogens, and of assessments of what such analyses teach about the management of crops so as to decrease losses caused by plant pathogens to economically low levels and, in agricultural terms, more or less permanently.

The book begins with a short account of the systems concept and of the properties, analysis and management of systems. This is useful and interesting to the uninitiated such as the reviewer. The main substance of the book starts with chapter 2, which first describes plant pathosystems, defined as any subsystem of an ecosystem which involves parasitism. It then characterises the "esodemic" and the "exodemic" as parts of epidemics that depend, respectively, on infection from within (auto-), and from outside (allo-) crops and which are therefore of quite different significance in the development of epidemics especially in relation to the type of disease resistance that controls infection.

Chapters 3–6, as the core of the book, deal in depth with analysis and management of pathosystems comprising either interactions between vertical resistance and vertical pathogenicity, or between horizontal resistance and horizontal pathogenicity. Subjects discussed include the properties of vertical and horizontal resistance in genetical and epidemiological terms, the nature and role in disease of gene-for-gene relationships and of strong genes, genetic flexibility of host and pathogen in relation to the origin and developments of epidemics, and the paramount importance of horizontal resistance in crop management both generally and as illustrated by many well-chosen examples of important diseases of crops of different types, and especially of maize and sugar-cane.

Chapter 7 is concerned with the operation of some of these factors in polyphyletic crops, again illustrated with examples, and chapter 8 is a short review of the nature and assessment of the vulnerability of crops to serious damage by pathogens, and how vulnerability can be decreased by various measures which prevent, or prepare for, the exposure of crops to virulent pathogens.

Chapter 8 contains a series of conclusions which emphasise the value of the systems concept and of well conceived programs of domestication of crop plants which exploit the superior qualities of horizontal resistance. A last chapter on terminology defines or describes, often at some length, no fewer than about 300 words, terms and concepts in some 24 pages. This is a particularly valuable and essential part of the book. There are about 100 references, a small number in relation to the scope of the book; even so, a few are unexpected. The shortness of the list is explained by the circumstances and style in which the book was written. In contrast, there is an extensive index of about 1,000 entries.

Mr Robinson states in his Preface that his book is theoretical and speculative. But much of it is a good deal more than theoretical, as would be expected from Mr Robinson's background; and the speculation is reasoned and not unrealistic. Quite a lot of the book is controversial. Thus, Mr Robinson's concept of vertical and horizontal resistance will be regarded as oversimplified by plant pathologists who have studied resistance at the cellular and molecular levels. Also, Mr Robinson does not like the extensive use of vertical resistance in plant breeding and says so very plainly. But he is an enthusiast for the use of horizontal resistance whenever possible and that, in his opinion, should be almost always.

Some plant breeders will not agree with the extremities of his approach. The writing from time to time is forthright and provocative but attractively so and certainly should not offend those against which it is sometimes quite pointedly directed. The book is well and clearly written but must be taken slowly because almost each paragraph on each page contains one or more substantial points which must be understood if the main themes which are propounded are to have their full impact. But the effort called for is very well rewarded because few books published on plant pathology during the past three decades are so stimulating, challenging, and have been written with such worthy objectives. *Plant Pathosystems* will undoubtedly cause quite a stir among plant pathologists and plant breeders, for most of whom it must be regarded as compulsory reading.

R. K S. Wood is Professor of Plant Pathology at Imperial College, University of London, UK.

Laser physics

Principles of Lasers. By O. Svelto. Pp. x+376 (Plenum: New York and London, 1976.) \$30.00.

THERE is light, and light. Or as Svelto might put it, the properties and quality of radiation can be defined and quantified by the first, and higher-order, correlation functions of the electromagnetic field. Thus, to first-order the coherence of laser light is revealed in its exceptional brightness and monochromaticity. The unique spatial and temporal coherence of such sources has already led to a number of practical applications, and largely accounts for the current scientific interest in this subject.

This book develops the theory and techniques of laser physics from first principles (quantum mechanics and electromagnetism), is completely self-contained, and should prove of particular value to the undergraduate reader. The text is well illustrated, very carefully referenced, and includes imaginatively chosen questions at the close of each of its nine chapters. (Problems in the introductory chapters, for example, range from black-body radiation to practical design problems of ruby, dye, He-Ne and CO_2 lasers.) Pumping processes, passive optical resonators, continuous and transient energy extraction (including the semiclassical treatment of π pulses, photon echoes and passive-mode-locking) are treated in detail; illustrative applications, including holography and optical data-processing, are treated more generally. Topics involving quantisation of the electromagnetic field (such as laser noise) are not discussed.

In my opinion, unstable optical resonators warranted a more extensive discussion for example, the importance of diffuse apertures was not considered, and Ananev's work was not referenced. Surprisingly, the highly efficient CO laser and recent Kr_2^* and Ar_2^* excimer (and halide exciplex) lasers receive no mention. These are, however, minor criticisms of a book which has been carefully translated and which makes excellent reading.

WILEY INTERSCIENCE

INTRODUCTION TO THE RENORMALIZATION GROUP AND TO CRITICAL PHENOMENA

by **P. Pfeuty** and **G. Toulouse,** *Université de Paris-Sud, Orsay, France*

Translated from the French by **G. Barton,** *School of Mathematical and Physical Sciences, University of Sussex.*

This book is intended as an introduction to an extensive domain within physics which has grown around certain problems in field theory, statistical mechanics, solid state physics, chemical physics, and elsewhere. In the space of a few years, the subject has grown from a set of vague analogies to a domain thoroughly unified by methodology and by the language of the renormalization group. Some regions of the domain have been well explored (for example, critical phenomena in phase transitions, various problems in field theory, the statistical mechanics of polymers, the Kondo effect) while others are hardly touched (for example, dynamical critical phenomena, inhomogeneous media, one-dimensional metals, instabilities in steady states in the fields of hydrodynamics, chemistry and biology, and many problems concerning elementary particles).

0471 99440 5 200 pages February 1977 £9.00/$18.50

EXPERIMENTAL REACTOR PHYSICS

by **A. E. Profio,** *University of California, Santa Barbara.*

Presents a complete and up-to-date treatment of neutronic experiments, including experiments and techniques of radiation measurements in moderators, subcritical assemblies, critical assemblies and nuclear reactors. Emphasizes the physics of the situation, and the importance of estimating error as well as the mean value of a measured quantity.

0471 70095 9 826 pages March 1976 £20.25/$35.00

ORGANIC ELECTRONIC SPECTRAL DATA: Vol. 11: 1969

edited by **J. P. Phillips,** *University of Louisville,* **H. Feuer,** *Purdue University,* **P. M. Laughton,** *Carleton University,* and **B. S. Thyagarajan,** *University of Texas, San Antonio.*

This series abstracts and publishes in formula order all the ultraviolet-visible spectra of organic compounds presented in the journal literature All entries are organized according to the molecular formula index system used by Chemical Abstracts.

0471 68802 9 1072 pages February 1976 £29.90/$51.60

INTRODUCTION TO ECOLOGICAL ANTHROPOLOGY

by **D. L. Hardesty,** *University of Nevada.*

This comprehensive introduction to modern anthropological thought examines the role of the environment in relation to human behavior. Organized around the concept of the ecological system, it emphasizes human population as the focal point of ecological studies Ethnoecology and the use of ecological principles and methods in paleoanthropology and pre-history are also discussed.

0471 35144 X 320 pages February 1977 £9.35/$16.00

VIRAL INFECTIONS OF HUMANS: Epidemiology and Control

edited by **A. S. Evans,** *Yale University School of Medicine, USA.*

This book provides a comprehensive presentation of all major viral infections of man, with major emphasis on epidemiology and control. It fits between basic texts on virology and the larger books on clinical infectious diseases. Each chapter is divided into ten sections: introduction, history, methodology, characteristics of the agent, descriptive epidemiology, mechanisms and route of transmission, pathogenesis, patterns of host response (clinical features, diagnosis), prevention and control, and unsolved problems.

0471 99435 9 616 pages February 1977 £23.00/$44.00

(Available from Wiley in the U.K., Europe and Africa [not Israel]).

EVOLUTION, BRAIN, AND BEHAVIOR IN VERTEBRATES

Vol. 1: Modern Concepts

edited by **R. B. Masterton,** *Florida State University;* **M. E. Bitterman; C. B. G. Campbell,** and **N. Hotton.**

With chapters devoted to particular groups of vertebrates, this collection of articles presents an up to date overview of the evolution of vertebrates in terms of the development of their brain, sensory receptors, and other nervous system components.

0470 15045 9 496 pages February 1977 £22.45/$35.00

Vol. 2: Persistent Problems

edited by **R. B. Masterton,** *Florida State University;* **W. Hodos** and **H. Jerrison.**

This volume concentrates on method, discussing comparative method and homology. Topics discussed include: Comparative Method of Investigation; Principles of Evolution of the Brain and Behavior; Practical Aspects of Homology and Recognition; Problems in the Comparative Study of Language.

0470 15046 7 286 pages February 1977 £11.20/$19.00

Published by Lawrence Erlbaum Associates and distributed by John Wiley & Sons Ltd.

ADVANCES IN PSYCHOBIOLOGY Vol. 3

edited by **A. H. Riesen,** *University of California, Riverside,* and **R. F. Thompson,** *University of California, Irvine.*

Assembles recent research and current knowledge about behavioral changes and the nervous system. Experts delve into recent findings about day-night behavioral rhythms, sex differences in feeding behaviors and appetite, visual development as a function of the environment, and changes in the brain related to learning experience.

0471 72173 5 510 pages September 1976 £18.45/$32.25

Practical Methods in Electron Microscopy, Volume 5

edited by **AUDREY M. GLAUERT,** Strangeways Research Laboratory, Cambridge, England.

1977. about 556 pages. Price: US $71.25/Dfl. 178.00. ISBN 0-7204-0605-6. Hardbound.

The books in this series provide enough detailed information for newcomers to carry out well-established techniques with success. Each volume is published in a hardbound edition for reference purposes and individual parts are published in paperback for easy use in the laboratory.

Part I

Staining Methods for Sectioned Material

by **P.R. LEWIS,** Physiological Laboratory, University of Cambridge, England, and **D.P. KNIGHT,** Biology Department, King Alfred's College, Winchester, England.

1977. about 332 pages. US $22.50/Dfl. 56.00. ISBN 0-7204-0606-4. Paperback.

The aims of this part are twofold: to help the beginner to choose between the bewildering variety of published techniques and to provide a compact source-book of those particular techniques which have proved to be both useful and reasonably easy to use. To achieve the first aim some discussion is included of the underlying chemical basis of the staining techniques. Acquaintance with histochemical techniques at the light microscopical level will help in the understanding of the more complex staining procedures described but it is anticipated that the beginner will find this volume self-sufficient. Some of the more complex cytochemical techniques are included, but the main emphasis is on providing full practical details of basic and dependable methods for use by the average electron microscopist, rather than on covering all the latest modifications and applications.

Part II

X-ray Microanalysis in the Electron Microscope

by **JOHN A. CHANDLER,** Tenovus Institute for Cancer Research, Welsh National School of Medicine, Heath, Cardiff, Wales.

1977. about 232 pages. Price: US $17.75/Dfl. 44.00. ISBN 0-7204-0607-2. Paperback.

This laboratory manual describes, for the uninitiated and experienced alike, the principles of X-ray microanalysis together with the range of instruments and techniques available for producing, measuring and interpreting the X-ray signals. The preparation and handling of thin specimens in the TEM and thicker samples in the SEM are discussed in detail for both biological and physical materials. Throughout, major emphasis is placed on practical details, and a wide range of applications is used to illustrate the practical problems involved in specimen preparation and analysis.

Clearly illustrated to provide an easy-to-read and comprehensive reference to all aspects of X-ray microanalysis in the electron microscope, this book should find a place in laboratories of cell biology, zoology, chemistry, mineralogy, physics and metallurgy.

In preparation

Volume 6 Part I Autoradiography and Immunocytochemistry

Part II Quantitative Methods in Biology

by **M.A. WILLIAMS,** Reader in Human Biology and Anatomy, University of Sheffield, England.

Calcium in control

Calcium in Biological Systems. (Symposia of the Society for Experimental Biology.) Edited by C. J Duncan. Pp. viii+485. (Cambridge University: Cambridge, London and New York, 1976.) £18.

THE study of extracellular calcium metabolism and its hormonal control has progressed steadily over many years. Interest in intra-cellular roles of calcium, confined for some time to its regulatory function in muscle, has recently grown rapidly following independent advances in several areas. Calcium is now known to be a key factor in triggering secretion, activating cells for division, controlling intercellular communication and regulating glycolysis and respiration, in addition to its involvement in contractile systems and in nervous conduction.

This latest Symposium of the Society for Experimental Biology considers mainly these intracellular systems. The organisers have concentrated attention on the general problems of how intracellular calcium levels are controlled, rather than on the detailed analysis of the effector roles of Ca^{2+} which differ greatly in different systems. This is a particularly difficult experimental field for the very reason that calcium is such a good controlling ion; its intracellular concentration is normally in the submicromolar range so that small fluxes have large effects.

It is only within the last five or ten years that the discovery of aequorin by Shimomura and Johnson has provided a direct approach to its measurement. These authors contribute a useful paper on the properties of this interesting luminescent protein and other papers by P. F. Baker and C. C. Ashley *et al* describe its application in nerve axons and in muscle fibres. Baker also provides a good general analysis of intracellular Ca^{2+} regulation, and Ashley *et al.* consider the technical problems in the quantitative interpretation of aequorin luminescence They also describe the use of a microscintillator probe to follow the influx of $^{45}Ca^{2+}$ but they do not evaluate the relative merits of these two techniques.

Two good introductory chapters deal with the general chemistry of Ca^{2+} and its complexes (R. J. P. Williams) and with a variety of natural and synthetic ionophores for divalent cations (M. Truter). I missed a similar introductory section on the use of electrophysiological techniques and concepts and the uninitiated will find unfamiliar jargon and usage in this field. For example, the significance of a potentially interesting paper on the effects of intracellular calcium on membrane permeability (R. W. Meech) was obscured by the use of the term 'activation' in different and undefined senses.

Almost half of the twenty papers concern contractile systems and three of these were on troponin. A clear account of its evolutionary relationships with parvalbumins and myosin light chains, based on amino acid sequences (J. H. Collins), was complemented by a comparison of control functions in different species and a study of the functional interchangeability of these regulatory proteins *in vitro* (A Szent-Gyorgyi). It was pointed out (S. Ebashi *et al.*) that in spite of such homologies one must be cautious about arguing too closely from the regulatory mechanisms in skeletal muscle to other situations, since in smooth muscle, for example, calcium behaves as an activator rather than as a derepressor.

Several papers considered the problems of coupling between excitation and contraction. In skeletal muscle (S. R. Taylor and E. Godt) a depolarisation induced release from sarcoplasmic reticulum is the main physiological mechanism. The more complex situation in heart muscle is reviewed at the physiological level by R. Niedergerke *et al*, and some of the biochemical problems are discussed by E. Carafoli and M. Crompton in their critical evaluation of the role of mitochondria in Ca^{2+} regulation.

One conclusion to be drawn from several of the contributions is that with the exception of sarcoplasmic reticulum and of Ca^{2+} uptake by mitochondria, little is known about the nature of intracellular calcium stores and their control. The large reservoir of calcium in the nucleus can best be described as a pool of ignorance.

The conference is ably summarised in a concluding chapter (A. Weber) which also mentions relevant points from the discussion These tantalising glimpses make one wish that a more extensive record of this part of the meeting could have been included in the book. Nevertheless, the account as it stands provides a valuable survey of a diversifying and developing subject. It will be particularly valuable to workers in the calcium field who wish to keep up-to-date with advances in less familiar parts of their subject.

N. Michael Green

N. Michael Green is a member of the MRC staff, working at the National Institute for Medical Research, London, UK.

'By the year 2009 twice as much food, water, energy and mineral ore will be needed to maintain man in his present state of comfort – or discomfort.

Conservation of Resources

Since the 1973 oil crisis the Western industrialised nations have come to realise that not only oil but almost all resources on which their high standard of living depends are in a finite state of supply, and that the Third World nations are likely to demand a fairer share of these limited resources.

In this book recognised authorities in their fields present a wide-ranging look at the problems of conservation in terms of future energy needs and energy sources, human energy needs and food supplies, mineral resources and the often ignored areas of fresh air and fresh water.

Pragmatics

Language and Context: The Acquisition of Pragmatics. (Language, Thought and Culture: Advances in the Study of Cognition.) By E. Bates. Pp. xiv+375 (Academic. New York and London, 1976.) $19.95; £12 20.

PSYCHOLINGUISTICS has traditionally depended on linguistics proper to supply research topics. When linguists produce a rule to which the sentences of our native language can conform, psycholinguists can then go off and try to explain either the sense in which we "know" this rule, or how we manage to act as if we knew it. Until quite recently, the rules in question were almost exclusively rules of syntax, and the psycholinguist's problem was, for instance, to explain the mental organisation that might lead us to exclaim "Ah, there's the book that I was hunting for!" but never "Ah, there's the book that I was wondering where was!".

In the past few years, however, linguists have been giving increasing attention to the study, under the heading of "pragmatics", of the conventions surrounding the use of various linguistic forms. For instance, "Can you shut the window" has a syntactic form normally associated with questions, yet it might easily function as a request. Furthermore, it is a more polite request than a simple "Shut the window". In some circumstances, "Do you think it's a bit chilly in here?" might be more polite still, although at other times it will just be annoyingly indirect.

The psycholinguist Elizabeth Bates has set out to chart the mastery by children of these, and other, subtleties of linguistic usage. Working from studies of pre-school age Italian children, she marks the onset of such phenomena as talking about talking, laying emphasis on particular words, discussing situations beyond the here and now, and wording an appeal for a sweet so as to make it as persuasive as possible She also considers, from the standpoint of Piaget's theory of cognitive development, what mental capacities are required to reach these pragmatic milestones, and so sets linguistic development in the context of general cognitive development.

Professor Bates has written an excellent and fascinating book. She is considerate to the reader, explaining clearly and carefully both the theoretical background, and the design and interpretation of her experimental studies It is a book pregnant with possibilities for further research, and one can only hope that others who follow her, mantain her standards of liveliness and clarity. **S. D. Isard**

S. D Isard is Lecturer in Experimental Psychology at the University of Sussex, UK.

Air pollution

Effects of Air Pollutants on Plants. (Society for Experimental Biology, Seminar Series 1.) Edited by T A Mansfield Pp. 209. (Cambridge University. Cambridge, London and New York, September 1976.) Hardcover £8 50; paperback £3 80.

THIS volume appears 15 months after the seminar on which it is based. The authors have concentrated on their own findings, and consequently much material appears here for the first time; coverage is uneven and references highly selective. Less understandably, there is no attempt to place the contributions in a wider framework or to define the outstanding problems. For example, the chapter on uptake of pollutants (Unsworth, Biscoe and Black) mentions only the resistance analogy approach; such work surely should form the basis for simulation modelling of the growth of polluted crops. but nowhere in the book is this suggested. Only Bradshaw on evolution and pollution gives an integrated account of his field The central challenge of bridging laboratory and field observations is raised both for fluorine (Davison and Blakemore) and for ozone (Manning and Feder)—the latter authors, like most Americans, eschew growth analysis. Both of these chapters find contradictions between laboratory and field data: could the method of expressing pollutant levels (as mean, peaks or dose) be partly responsible? The singular properties of open top chambers (McCune, Maclean and Schneider) make it unlikely that this type of enclosure will yield unambiguous results By recording changes in enzyme activities following fumigations, the Lancaster group point the way to pollutant-specific physiological tests Would that more work on SO^2 and lichens were as analytical as that described here (Nieboer, Richardson, Puckett and Tomassini) Two useful appendices summarise data on air chemistry and references to biochemical effects. Overall, we are given valuable data but little perspective; a book for the specialist

J. F. Farrar

J F. Farrar is Lecturer in the Department of Botany at the University of Liverpool, UK.

Soils of arid regions

Soils of the Arid Regions. (Developments in Soil Science 6.) By H. E. Dregne. Pp. xii+237. (Elsevier Scientific. Amsterdam, Oxford and New York, 1976.) Dfl. 75.00; $28.95.

THE aim of this book in attempting to collect together the available information on arid region soils is highly commendable. In attempting to cover such a vast topic in only 223 pages, however, the author sets himself an impossible task. The inevitable result is a book which is too specialised for the layman and too superficial for the professional pedologist.

From a brief introduction to arid regions (excluding polar deserts) the author moves on to consider with little comment, various approaches to the classification of arid region soils, finally selecting the USDA 7A scheme as a basis from which to work. Chapter three consists of a short discussion of each of the soil orders found in arid regions together with a cursory summary of the geomorphology of arid regions. In the following six chapters the distribution of arid soils is considered on a continental basis; accompanying each of these chapters is an absurdly small scale map showing the distribution of the principal associations of great soil groups. The choice of symbols is such that on several maps it is impossible to differentiate between alfisol, aridisol and mollisol groupings. This approach to the consideration of soil distribution leads to a mass of needlessly repetitive information on each great group, which could, together with better maps, have been condensed into one chapter. The last three chapters cover very briefly those chemical physical and biological properties of soils which are (according to the author) important for management. Throughout the whole text discussion on pedogenesis is extremely limited and very superficial.

The standard of the twenty-six line illustrations (there are no photographs) is extremely low: several are illegible and many others are irrelevant, adding nothing to the text.

Despite all these shortcomings, had the book been reasonably priced it could have been recommended, simply because it is the first text to attempt to draw together information on arid region soils With its outrageous price of about £19.00, brief coverage and appalling illustrations, however, there is no reason to recommend this book. Sadly there still remains a great need for a comprehensive text on the soils of arid regions. **M. J. Alexander**

M J. Alexander is Lecturer in Geography at the University of Durham, UK.

obituary

Professor Philip Macdonald Sheppard, FRS, died on October 17, 1976. He was an outstanding scientist, an inspiring teacher, a formidable adversary and a very good friend.

Philip Sheppard was born in 1921, the son of a schoolmaster. He was educated at Marlborough College. He joined the Royal Air Force Volunteer Reserve in 1940, and was a prisoner-of-war from 1942 to 1945. Immediately after the war he went up to Worcester College, Oxford, to read Zoology, and in 1948 was awarded a second class Honours Degree. It is said that he could easily have gained a 'first' had it not been for his single-minded devotion to genetics, the subject to which he dedicated the rest of his life.

He studied for the D.Phil. at Oxford under Dr (now Professor) E. B. Ford, and obtained the degree in 1951. From 1951 to 1956 he was Junior Research Officer in the Department of Zoology, taking a year off in 1954 to work with Professor Theodosius Dobzhansky at Columbia University. In 1956 he was appointed Senior Lecturer in Genetics in the Department of Zoology at Liverpool University. He was promoted to Reader in 1959. In 1963 he became the first Professor of Genetics at Liverpool, and remained in this post until his death. He was elected to a Fellowship of the Royal Society in 1965, and to an Honorary Fellowship of the Royal College of Physicians in 1975. In 1974 he was awarded the Darwin Medal of the Royal Society, and in 1975 the Gold Medal of the Linnean Society.

The bare description of a distinguished career shows little of the great impact that Philip Sheppard made on the study of ecological genetics. He had an almost uncanny ability to see the next step in an argument, the next experiment to be done. He applied this ability freely and generously to the work of others, and generated many an idea or experiment that came to be published under another name

His own work completed the transformation of ecological genetics from a science of observation to a science of experiment. His central interest lay in the mechanics of natural selection and its effects on the genetic constitution of organisms. This interest guided his work with Sir Ronald Fisher and Professor E. B. Ford on polymorphism in the moth *Panaxia dominula*, in which they finally demonstrated that the temporal changes of gene frequency were the consequences of natural selection. It motivated his studies with Professor A. J. Cain on polymorphism in the snail *Cepaea nemoralis*, studies which showed that spatial variations in this species were also due to selection, and which culminated in his beautiful experiments on selective predation by thrushes. It also guided the work with Sir Cyril Clarke on mimicry in butterflies of the genus *Papilio*, demonstrating the evolution of 'supergenes', linked polymorphic complexes of genes maintained in a state of linkage disequilibrium by strong selective interactions. Their interest in such interactions led Sheppard and Clarke to studies of human blood groups, bringing them finally to a method of preventing Rhesus haemolytic disease. Apart from these classic experiments, Sheppard also made important studies on the evolution of dominance, the genetics of industrial melanism in moths, heavy metal tolerance in plants, insecticide resistance in mosquitoes, and schizophrenia, anencephaly and spina bifida in man. In 1958 he published *Natural Selection and Heredity*, and the fourth edition was issued shortly before his death It is still the best introductory book about ecological genetics, and one of the rare breed of elementary texts that are quoted in the research literature because of the original ideas that they contain.

He was an exceptional teacher. His transparent intellectual honesty, his passion for truth and rigour, and perhaps above all his patent desire that his hearers should understand and enjoy his subject, made an enduring impression on his students. As a colleague and friend he was a delight, and a very good companion. His comments on cherished ideas or manuscripts were sometimes blunt to the point of pain, but they were always given with good humour, never tinged with malice. His friends said that he reversed the normal academic procedure, he stabbed you in the front, and then did you favours by stealth Hating pomposity, he was marvellously uncorrupted by success. As a distinguished Darwin Medallist he was much the same Philip Sheppard as the Junior Research Officer at Oxford. He bore his three-year illness with quite extraordinary courage and cheerfulness.

His life can be epitomized in the words of one who was also a prisoner-of-war. "To serve his vision, to protect it against all plausible substitutes, reasonable approximations and coward compromises is still, I believe, the knightly duty of contemporary man. He has only to remain steadfast in pursuit of it and his life will achieve something which is greater than happiness and unhappiness: and that is meaning."

B.C.C.

Sigurd Zienau died on October 18, 1976 at the early age of 55 years. He had been a Reader in Physics at University College London since 1965, following a period from 1954 as a Lecturer, and as ICI Research Fellow at Liverpool.

Dr Zienau was trained in the old school of European physics, being a student of Heitler, Pauli and Fröhlich, after a distinguished period as a mathematics undergraduate at Birkbeck College.

His name is familiar to solid state physicists as a co-author of the theory of the polaron through which, in 1950, field theory was introduced into solid state physics. He will also be remembered in the worldwide community of theoretical physicists for his important revisions of two classic texts in theory: both Heitler's *Quantum Theory of Radiation* (3rd ed.) and Mott and Massey's *The Theory of Atomic Collisions* (3rd ed.) owe much to his labour and insight. He had a phenomenal memory for the literature of theoretical physics and would recall from obscure journals published in the first half of the century the seminal work that could shed light on modern problems. His main research interests lay in scattering theory and electrodynamics, but he had a scholarly interest in a much wider range of subjects.

Dr Zienau's published papers do not, in quantity, do justice to his gifts. However, they are thoughtful contributions and each one represents the distillation of many months hard work, as well as hard argument, with his co-workers. There are three phases of his research represented in these papers. In the early 50s he published work on dielectrics, especially on the motion of slow electrons in polar materials. Later in the 50s and early 60s he published a series of six papers on electrodynamics including contributions to damping processes, line shapes, intermolecular forces (including retardation and three body interactions) and gauge problems. The final set of papers concern various specialised aspects of field theory.

He trained about ten research students who now teach throughout the world and these will always have that special magic that comes from having worked with and learned from Sigurd.

In recent years he interested himself in the history and philosophy of science and was active in the British Society for Social Responsibility in Science.

He will be sadly missed by his friends, colleagues and students at University College. He leaves a young daughter and son by his second marriage, and one son by his first.

E. A. Power
F. F. Heymann

J. V. Peive, the Soviet soil scientist, died after a long illness on September 13, 1976, aged 70. As well as being one of the leading Soviet agricultural scientists of the post-war era, Dr Peive had been politically active and, according to Tass, his official obituary was signed by Mr Brezhnev and other prominent Soviet politicians and scientists. Of Latvian extraction, he was born in 1906 in the adjoining Toropets district of Russia and, after training as a teacher, graduated in 1929 from the Timiryazev Agricultural Academy in Moscow.

For 13 years from 1931 he worked in the All-Union Flax Research Institute in Torzhok, some 200 km north-east of Moscow, rising to the position of Director. After the war he became Rector of the Latvian Agricultural Academy in Riga, carrying out his own specialist investigations in the Laboratory of Biochemistry of Soils and Trace Elements in the Institute of Biology. He published a text-book on the biochemistry of soils in 1961 but will be best remembered for his work on the effects of trace elements in soils on plants and animals. Several volumes of the Transactions of his laboratory, dealing with different aspects of trace element problems, have been published by the Latvian Academy of Sciences, and he chaired the Co-ordinating Commission on Trace Elements in Soils, Plants, Animals and Human Nutrition in the USSR. Dr Peive's wider interests in soils were recognised by his appointment as Editor-in-chief of *Pochvovodenie*, the Soviet journal of soil science, a post that he had occupied for the past 14 years.

Peive rose to the Presidency of the Latvian Academy of Sciences and, after 13 years as a Corresponding Member, was elected an Academician of the Academy of Sciences of the USSR in 1966, in which he held the post of General Secretary. He was Prime Minister of Latvia from 1959 until 1962 and was one of the three Latvian representatives in the Soviet of Nationalities, one of the two Chambers of the Supreme Soviet of the USSR, and Chairman between 1958 and 1966.

He seldom attended scientific gatherings outside Russia, although only ill-health prevented his participation in the meeting of Commissions II and IV of the International Society of Soil Science in Aberdeen in 1966. In private discussion he talked about his work with much less formality than is the case with many Soviet scientists and often introduced a light-hearted note. His major contribution to Soviet agriculture was in the immediate post-war years when he pointed out the existence of trace element problems in many Russian soils, particularly deficiencies of boron, zinc, manganese, cobalt, copper and molybdenum.

R. L. Mitchell

Professor Leo Pincherle died suddenly on October 25, 1976 I came to know him well during the last years of his life He regularly attended the Bedford/Westfield College solid state physics seminars. Characteristically, he spoke little at these meetings, but his rare contributions were profound and to the point. He was modest to a fault and abhorred the limelight; yet his colleagues, friends and students know of the innumerable unobtrusive ways in which he served the cause of scholarship in teaching and research.

Leo Pincherle was born in Bologna in 1910. He came from a line of distinguished academics—the mathematician Salvatore Pincherle was a grandfather—but Leo was the first of the family to take up physics as a career. His first publication (1931) reported a calculation of the wavelength of the oscillations in Hull's magnetron; and the interest in the theoretical principles underlying practical devices marked his work to the end. He was with Fermi in Rome, later moved to Padua and came to England shortly before the Second World War as a refugee from Mussolini's Italy During the difficult years which followed he was befriended by the late H T Flint who brought him as a lecturer to King's College, London. Leo's early research, on a variety of topics in spectroscopy, atomic physics and electromagnetic theory, demonstrates the width of his scientific interests. But his great productive period came at the Telecommunications Research Establishment (TRE), Malvern, where he was Principal Scientific Officer from 1948 until 1955. Here he established himself as a leading authority on energy band theory. The 1953 paper on the band structure of lead sulphide (Bell *et al.*), in which the cellular method was first applied to a diatomic semiconductor, is an early classic in the field, and fundamental theoretical work on applications of group theory appeared in the form of TRE Memoranda Pincherle returned to university life in 1955 when he rejoined Flint, by then head of the physics department at Bedford College, London, as a University Reader; overdue promotion to Professor of Mathematical Physics came in 1969. A fruitful collaboration with P. M. Lee led to further band structure papers in the early 1960s. In the last ten years of his life Leo Pincherle published few research papers. But he continued to be active and fertile in the many other ways a scholar exerts his influence: as supervisor of research students, as a sought-after contributor to summer schools in Italy, as UK editor of the international journal *Solid State Electronics,* and not least as author of the definitive textbook *Electronic Energy Bands in Solids* (1971) which itself contains much original work. Above all Leo Pincherle loved teaching and the contact with his students, a love which was fully returned, and the prospect of retirement from this activity filled him with dismay. Leo's lectures and publications all bear the stamp of his characteristic approach to physics careful preparation, great clarity and economy of style, the use of the simplest mathematical techniques appropriate to the physics of the problem in hand. He tackled difficult problems but was never a narrow specialist.

The picture of Leo Pincherle the scientist cannot be separated from that of Leo Pincherle the man. He was devoted to his family, for whom his too-early death is a tragic loss. His sense of humour, dry and delicious, showed in his fund of stories about well-known contemporaries — always amusing and never malicious. His quiet demeanour concealed plenty of fire and imagination, as you soon discovered when you partnered him at bridge. He was the most knowledgeable of men on fundamental aspects of European culture and history and wore his learning lightly; his love of music and the arts was intense, his taste discriminating. He was, in the best sense, both very Italian and very English, combining in his person that internationalism in science and that European spirit which it is so necessary to keep alive today. His friends miss him deeply.

Ernst Sondheimer

announcements

Awards

The Lomonosov medals—the highest award of the Soviet Academy of Sciences—for 1976 have been awarded to **Academician S. I. Vol'fkovich** of the Soviet Academy of Sciences for his work on the chemistry of phosphorous, and to **Dr Hermann Klare**, President of the Academy of Sciences of the German Democratic Republic, for his work on artificial fibres.

The Royal Astronomical Society Gold Medal has been awarded to **Mr John Bolton**, a Chief Research Scientist with the CSIRO Division of Radiophysics at Parkes, NSW, for outstanding contributions to both radio and optical astronomy, particularly for his studies of radio sources in space.

The Clough Medal for 1976–77 has been awarded to **Professor T. S. Westoll**, FRS, Department of Geology, University of Newcastle upon Tyne for contributions to geology, in particular studies of fossil vertebrates and their application to the stratigraphy of the Old Red Sandstone of Northern Scotland. The Clough Award for 1976–77 has been conferred on **Dr E. N. K. Clarkson** of the Grant Institute of Geology, University of Edinburgh, for his work in palaeontology and palaeoecology, in particular on the eyes of trilobites and including trilobites from the Lower Palaeozoic rocks of Scotland

The Faraday Medal has been awarded to the Executive Director-General of the CERN Laboratories in Geneva, **J. B. Adams**, for his contribution to the design and construction of high-energy particle accelerators.

Meetings

14 March, **Ion Implanted Semiconductor Devices**, London (Institution of Electrical Engineers, Savoy Place, London WC2).
15 March, **Vehicle Navigation and Identification**, London (Institution of Electrical Engineers, Savoy Place, London WC2).
26–28 March, **Changing Sea Bird Populations Of the North Atlantic**, Aberdeen (G Sarle, Royal Society for the Protection of Birds, Sandy, Beds.).
29 March–1 April, **Submillimetre Waves and their Applications**, Surrey (Institute of Physics, 47 Belgrave Square, London SW1).
5–7 April, **Energy in the 80s**, Middlesbrough (Institution of Chemical Engineers, 165–171 Railway Terrace, Rugby).
18–20 April, **Advances in Extractive Metallurgy**, London (Institution of Mining and Metallurgy, 44 Portland Place, London W1).
19–20 April, **Strain Rate Method of Stress Corrosion Testing**, Newcastle upon Tyne (Society of Chemical Industry, 14 Belgrave Square, London SW1).
9–11 May, **Hepatotrophic Factors**, London (Ciba, 41 Portland Place, London W1).
17 May, **The Changing Face of Cancer**, London (Marie Curie Memorial Foundation, 124 Sloane Street, London SW1).
22–25 May, **Autoradiography in Pharmacology and Toxicology**, Uppsala (S. Ullberg, University of Uppsala Biomedical Center, Box 573, S-751 23, Uppsala, Sweden).
31 May–2 June, **Lasers in Chemistry**, London (M. West, The Royal Institution, 21 Albemarle Street, London W1).
1–2 June, **30th Chemists' Conference**, Scarborough (K. Speight, BSC, Sheffield Laboratories, Hoyle Street, Sheffield).
15–26 August, **Scientific and Mathematical Foundations of Engineering Acoustics**, Cambridge, Mass. (MIT, Room 3-366, Cambridge, Mass. 02139).
31 August–2 September, **Cell–Cell Recognition**, Oxford (A. S. G. Curtis, Cell Biology, University of Glasgow, UK).
4–8 September, **Low Energy Ion Beams**, Salford (Institute of Physics, 47 Belgrave Square, London SW1).
10 September, **The Microscopic Structure and Dynamics of Liquids**, Corsica (J Dupuy, Physics, University of Lyons, 69621 Villeurbanne, France).
13–16 September, **Scintillation Counting**, Bath (The Secretary, Analytical Division, Chemical Society, Burlington House, London W1).
26–28 September, **On-line Surveillance and Monitoring of Process Plant**, London (E. Wakely, Society of Chemical Industry, 14 Belgrave Square, London SW1).
2–4 October, **5th Biennial Symposium on Turbulence**, Rolla, Missouri (J. L. Zakin, Chemical Engineering, University of Missouri, Rolla, Missouri 65401).
10 October, **The Display of Nondestructive Testing Data**, London (Institute of Physics, 47 Belgrave Square, London SW1).
19–21 October, **Current Topics in Drug Research**, Uppsala (R. Dahlbom, Biomedical Center, University of Uppsala, Box 574, S-751 23, Uppsala, Sweden).
9–11 November, **Atherosclerosis**, Milan (Fondazione G. Lorenzini, Via Montenapoleone 23, Milano, Italy).
28 November–2 December, **Protons and Ions Involved in Fast Dynamic Phenomena, Paris** (C Troyanowsky, 10 rue Vauquelin, 75231 Paris Cedex 05, France).
23–28 February 1978, **5th International Wheat Genetics Symposium**, New Delhi (M. V. Rao, Cummings Laboratory, Indian Agricultural Research Institute, New Delhi–110012, India).
10–14 April, **9th International Symposium on Carbohydrate Chemistry**, London (J. F. Gibson, The Chemical Society, Burlington House, London W1)
12–14 April, **4th European Immunology Meeting**, Budapest (The Secretariat, c/o MOTESZ, H-1361 Budapest, Hungary).
17–20 April, **10th National Atomic and Molecular Physics Conference**, London

Person to Person

The Einstein Archive is at work on a Collected Edition of the Papers of Albert Einstein. Would anyone in possession of, or knowing the whereabouts of, original manuscripts, letters to or from Professor Einstein, or documents or letters mentioning him, of which they are not sure that the Archive already has copies, please contact The Einstein Archive, Institute for Advanced Study, Princeton, N.J. 08540.

Exchange large furnished house Berkeley for one in London, July 1977 to August 1978. Pleasant neighbourhood, near schools and public transport and within walking distance of the University of California (1 mile). Transportation to San Francisco very convenient. Exchange of car (Saab) also considered Please contact: Dr Richard Malkin, 1967 El Dorado, Berkeley, California 94707, U.S.A.

There will be no charge or this service. Send items (not more than 60 words) to Marcus Dobbs at the London office. The section will include exchanges of accommodation, personal announcements and scientific queries. We reserve the right to decline material submitted. No commercial transactions.

(Institute of Physics, 47 Belgrave Square, London SW1).

20–25 August, **3rd European Conference on Analytical Chemistry,** Dublin (Euroanalysis III, Institute for Industrial Research and Standards, Ballymun Road, Dublin 9, Ireland).

4–7 July, **7th International Cryogenic Engineering Conference and Exhibition,** London (Institute of Physics, 47 Belgrave Square, London SW1).

20–25 August, **Plant Cell and Tissue Culture,** Calgary (IAPTC Congress, University of Calgary, Calgary, Alberta, Canada).

21–25 August, **4th International Congress of Cybernetics and Systems,** Amsterdam (J. Rose, c/o College of Technology, Blackburn, UK).

4–8 September, **4th International Symposium on Physical Organic Chemistry,** York (J. F. Gibson, The Chemical Society, Burlington House, London W1).

11–15 September, **Thin Film Properties in Relation to Structure,** Loughborough (Institute of Physics, 47 Belgrave Square, London SW1).

More Interdisciplinary Theses

IN the past couple of years, academics in Britain have been urged by the Science Research Council to look at the style of postgraduate education provided by the Massachusetts Institute of Technology (MIT) and to think seriously about transplanting some of its best features to British universities. Particular attention has been drawn to the extensive course work done in the first year or two at the postgraduate level, the subsequent examination, success in which has been necessary before a thesis could be ventured into seriously, and the (by British standards) free-flowing interdisciplinary character of much of the work that a student would do. But how does MIT see its own intellectual future—is there to be more innovation in postgraduate education or is the present mixture regarded as about right?

MIT administrators see a variety of trends as both restricting and demanding future change. There is a general feeling that the shape of postgraduate education in terms of requirements is satisfactory and should not be tampered with. But the content is another matter; defence and space were the two big customers for MIT PhDs and for research projects at the institute in the 1960s, and this wave has now broken. Present day and near-future demands on science and engineering research are much more closely related to what one person described as 'ways of engaging reality', such as increasing industrial productivity, solving energy problems and looking at questions in biomedical engineering and in transportation. These are interdisciplinary problems *par excellence* and there seems general agreement that the interdisciplinary revolution at MIT has not yet run its course. There is a pretty clear lesson here for some of the narrow self-regarding departments in British universities.

New commitments to multidisciplinary research and education are bound, however, to come up against the severest of financial and administrative obstacles. A report last summer by an MIT committee charged with looking at the institute's research structure painted a generally gloomy picture of federal support levels which have stagnated for several years, and of the research environment, which many believed had declined in recent years largely as a result of increasing pressure on faculty to raise research funds and a concomitant drop in flexibly-available resources. The committee endorsed the singular mix which MIT had evolved of departments, inter-departmental research programmes and specific laboratories and saw, in particular, research centres on campus as a way to proceed for the next decade; such concepts would be bound to influence the content of the education provided.

But if there are still new academic horizons, however shaky the funding prospects, there is one factor which is causing a lot of worry: changing levels of student enrolment in the next twenty years. Projections for the next ten years by the National Center for Education Statistics of the US Office of Education see a steady growth in bachelors degrees awarded in science and engineering up to 1985, with all the growth taken up in engineering, the life and the social sciences. But thereafter demographic trends take over. The number in the postgraduate age group (22–25) in 1995 will have dropped by 20% compared with 1985. This means not only that some inferior colleges will probably have insufficient students to justify their continuation, but also that even the big names in education will find themselves competing fiercely by 1990 to attract students to justify staffing levels.

And even before 1990 the PhD emerging from an American university is likely to find the world much changed from its present scene. Allan Cartter, in his book *PhDs and the Academic Labor Market*, projects US academic needs for junior faculty for the next twenty years. Whereas before 1970 academe could gobble up every PhD produced, by 1985 on the most optimistic projections (assuming faculty take early retirements and so on) there will only be an academic job for one PhD in every six produced in the United States. The moral is farily obvious; discourage right now those who believe three or four years research is an admission ticket to a cosy faculty post somewhere; and go on broadening the scope of the PhD so that it becomes a very widely acceptable qualification. Hence the continuing talk of interdisciplinary postgraduate education. □

Assessing the Oklo phenomenon

Professor Alvin Weinberg, Director of Oak Ridge National Laboratory, Tennessee, comments on the lessons to be learned from the discovery of a natural reactor

THE Oklo River is a small stream that runs near the town of Mounana, Gabon; here there is a large, open-pit, uraninite mine which I visited a few months ago. Oklo has become famous ever since French scientists of the Commissariat a L'Énergie Atomique discovered in 1972 that the mine was the site of ancient spontaneous chain reactors some 1.8×10^9 years ago. At that time the uranium-235 concentration was about 3%, instead of its present 0.72%. This is the same concentration now used in the fuel of modern pressurised water reactors. Indeed, the reactors at Oklo operated for about 15,000 MW years—that is, the equivalent of 5 years of a modern 1,000 MW reactor—and reached a burn-up of about 25,000 MW days per ton of uranium, again about the same as is reached in a modern PWR.

The Oklo phenomenon is surely one of the most exciting scientific discoveries of the decade. I hope that it quickly becomes part of the common understanding not only of scientists, but also of laymen—just as Pithecanthropus Erectus or King Tutankhamen have become parts of the common, as well as the scientific, understanding. I am not unbiased in this desire. Despite all the fuss about nuclear energy, I am still an unabashed nuke. For me, the long-term alternatives to nuclear energy: solar energy (and its children—wind, waves, ocean thermal gradients, biomass), geothermal energy, and fusion are either too expensive (solar) or too small (geothermal) or too uncertain (fusion).

The path of conservation is all well and good for a developed country that has energy to conserve; it has little relevance for a country such as Gabon, or for that matter, most of the world that is bent on development. Nor can I take the talk about 'small is beautiful' or a 'fission-free bridge to a solar future' fully seriously. Has anyone demonstrated on a scale large enough to make the experiment convincing, that small is really beautiful rather than simply poor? Or can anyone speak so confidently about future heavy dependence on fossil fuel with the CO$_2$ in the atmosphere increasing at a rate of about 0.15% per year, probably because we are burning so much fossil fuel? No, it seems to me that nuclear energy will be necessary *especially in the long run.* The main job of the nuclear community at present then is to make nuclear energy acceptable—to construct a nuclear future that adequately deals with the shortcomings of nuclear energy—some real, some only imagined.

We are all familiar with the issues by now: proliferation, reactor safety, terrorism and sabotage, diversion, waste disposal. Of these issues, there is little question that in the public's mind, and indeed, in the minds of most scientists outside the nuclear community, waste disposal is the most serious concern. As long ago as 1952, James Conant, the president of the American Chemical Society, asserted that the public would reject nuclear energy as not being worth the candle because the safe, permanent disposal of radioactive waste posed an insoluble problem. The recent Flowers report, on nuclear power and the environment, regards the problem of waste disposal as being in an unsatisfactory state. The new California law requires that a technology for permanent waste disposal must be demonstrated before reactors can be built there.

Until Oklo was discovered, permanent waste disposal in geologic formation seemed to be a problem that could not be solved *in principle*: since the wastes remain hazardous for thousands of years, one generation simply could not perform a definitive experiment. But Oklo has done much to change this. During the course of the chain reaction some five tons of fission products and perhaps one-half this amount of plutonium and other transuranics were formed. Of the fission products, the gases, the alkalis and alkaline earths, and ruthenium disappeared. On the other hand, the rare earths and the plutonium, uranium, and presumably the other actinides, remained in place, within the limits of measurement (at least 80 per cent of the plutonium is accounted for). The strontium-90 probably decayed in place to zirconium-90; whatever leaching of alkaline earth fission products occurred took place over a time long compared to the 30-year half-life of the strontium-90.

IAEA

The Oklo site

Thus nature has performed the experiment, and the findings, on the whole, are reassuring. To be sure cesium-137, a soluble species, migrated from the site; on the other hand strontium-90 probably did not; and most important, the actinides, which pose the really long-term hazard (thousands rather than hundreds of years) remained in place.

Sceptics will still remain unconvinced; they wil argue that Oklo represented a special geologic situation, that we cannot be absolutely sure—and that anyhow, there really is something new and spooky about this whole radiation thing. This is the essence of the matter. I shall never forget Enrico Fermi, during one of the monthly information meetings we held in 1943 at the wartime Metallurgical Laboratory, reminding us that the unique significance of the chain reaction lay in its bringing mankind in contact with unprecedented amounts of radioactivity. Never mind that radiation has become one of the best, if not the best, understood physical insults to the biosphere. It nevertheles represents something most people are unfamiliar with and are therefore afraid of.

Unless our society accepts the reality of radiation, and the proposition that radioactivity can be safely sequestered, nuclear energy will founder. And this is why it is so important that Oklo become a household word. Fermi was not the first to achieve the chain reaction, nor was he the first to put large, concentrated amounts of radioactivity on earth. Nature had achieved this 1.8×10^9 years earlier. Although the Oklo event affected life in the immediate vicinity, our planet survived and the biosphere evolved. Perhaps 100 years from now, when we have become fully accustomed to man-made chain reactors, we will look back and wonder why so much fuss was made about the problem of radioactive waste disposal which nature had already demonstrated to be tractable. ☐

Grow your own grass

David Spurgeon examines a programme for improving agriculture in Antigua

A COMMON problem of Third World countries is an unfavourable balance of payments caused by a shortage of indigenous industry and a consequent reliance on imports from developed countries. This is particularly true of many of the small Caribbean islands, whose industries (when there are any) are often foreign-owned and more concerned with exports to an affluent overseas market than with self-sufficiency of domestic supplies.

The tiny, 108-square-mile island of Antigua is a case in point. Since a sugar cane company left the island some years ago, there has been little more than tourism and rum-making in the way of industry there—both the molasses for the rum and most of the beef for the tourists being imported. Where sugar cane once flourished, acacia bushes now grow like weeds. Yet much of this land, rocky and hilly though it often is, could be used for grazing cattle, and if only the grass and legumes were more abundant and of better nutritional quality, the island might become self-sufficient in beef and dairy production—and even export to other Leeward Islands.

This in fact is the aim of a research programme now being conducted in Antigua, Trinidad and Belize by the University of the West Indies (UWI) with the aid of a grant from Canada's International Development Research Centre. The programme began in 1972 and is now in its second phase. It has an Australian consultant, Dr Robert Burt of the Commonwealth Scientific and Industrial Research Organisation (CSIRO), and the experiment is being watched with interest not only by the agricultural ministries of the three countries concerned but those of the neighbouring territories of Guyana, Barbados, Jamaica, Guadeloupe, Martinique and Cuba as well.

Two meetings have been held of representatives of agricultural ministries of the region—including representatives from other islands—to look at results where tests are being carried out with material from the project. The most recent was held in Antigua from 29 November–1 December. The Antigua component of the project is directed by a New Zealander, John Keoghan, who has taught at McGill's Macdonald College and done research at the University of Guelph. He is assisted by Belal Ahmed, a microbiologist from Bangladesh, employed by the department of soil science at the UWI in St Augustine, Trinidad, Clive Devers from Guyana, a graduate assistant, and Perry Phillip, a technical assistant.

Interviewed in Antigua recently, Keoghan spoke of the implications of the project and the relevance of the Australian experience. All of the grasses growing in the Caribbean and thought of as 'native' to the area, actually come from Africa, he said, while the legumes come from the area itself. The soil in both regions of the world is heavy clay, and if work done in the Caribbean were applied to Africa it could revolutionise agriculture there.

"This is not far-fetched," he said. "This is what the Australians did. They went to South and Central America and found plants for Northern Australia, which is tropical. The legumes that dominate livestock agriculture in Northern Australia were originally growing as weeds in South and Central America."

There is a difference, of course. The Australians selected plants from acid soils for acid soil areas of their own. Keoghan and his colleagues collect plants from alkaline soils to match those of the dry areas where livestock graze both in the Caribbean and in Africa. So far, they have collected a total of about 1,000 grasses and legumes for planting in experimental plots, including 70 different varieties of grasses. They are carrying out a complete classification and description of the plants, and then are making an agronomic assessment under different growing conditions, for example with different types of soils, and in mixtures of grasses and legumes.

Two plots

Two experimental plots are being used, one of them near the old sugar mill, where the small amount of laboratory equipment required is also located, along with nursery facilities.

As basic as all this might seem to be, it has never been done before, according to Keoghan. Although there were earlier sporadic attempts at collection, classification and description, adequate records were not kept of them and plant collections disappeared.

Pasture legumes are important not only for their high protein content, but for their ability to fix nitrogen and thus act as a fertiliser for the grasses. This latter capability is all the more important to developing countries at a time of high fertiliser prices. Samples of legumes have been collected from all over the island as well as from other countries in the region.

Samples are selected from a six-square-metre area of each plot, the leaves are clipped and the yield is bagged, dried in ovens at the sugar factory and the weight measured. Nitrogen and protein content are determined, and records are kept of these measurements. Seeds are collected and examined, and then sent to CSIRO in Australia, which is the main centre of tropical legume research.

After two years of trials in these plots, the research group in Antigua is now beginning to mix the best grasses and legumes in field trials on heavy soils, and then will test them under actual grazing conditions. The types of soil used for such trials is representative of those found in much of the grazing area in Antigua. This is being done with 15 different grasses and 12 legumes, both singly and in mixed stands to determine the effects of the legumes and grasses on each other. The animal grazing tests will show whether, for example, the animals actually will eat the plants, and how well the plants grow again after grazing.

Basically, the idea is to narrow down the choice of grasses and legumes to determine the best varieties available for local conditions, and the most productive combinations when grown together, and to work out the most suitable management practices. It is the first time such a project has been undertaken in the Caribbean. ☐

Pasture legumes in moveable nursery made from railway cars

Scottish science and devolution

Martin Goldman looks at possible effects of devolution on science in Scotland

FACED with the present media overkill of the devolution debate, more and more Scots are displaying a traditionally 'British' response to the issue—apathy. At the risk of increasing the tendency, Scottish science deserves special attention, for the problem of reconciling the international horizons of science with the nationalist viewpoint is of wider relevance, even though it is still largely theoretical. The Scottish National Party, the spearhead of the independence movement, has not yet needed to produce a concrete science policy. They have not decided whether nuclear power is an invention 'o'er the de'il', much less what role it would play in an overall energy strategy, and have not even considered whether or how to continue as members of CERN.

More positive has been the concern of academics. A strong feeling against the devolution of Scottish universities was displayed in response to a questionnaire sent out by the Scottish Association of University Teachers. About 60% of the replies disapproved of devolution; 20% approved, 20% were neutral.

A paper on the whole subject presented to the government by Professor John Gunn, a theoretical physicist, and Andrew Thomson, an economist, gives the consensus view. They feel that universities ought to be international in outlook, and therefore anything hindering communications between British universities, especially the easy exchange of staff and students, is a bad thing. The decline of the international reputation of Trinity College, Dublin, since Irish independence is an example.

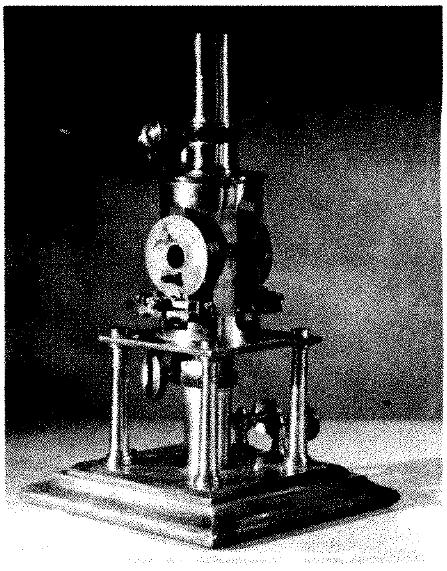
Their other major argument is that there exist economies of scale. Each university department has particular areas where it focuses its attention; Scottish universities do not cover a complete academic spectrum and are overproductive in certain areas (for example, Scotland, with 10% of the UK population, produces 150 vets a year out of a UK total of 350). Because of the expense of equipment, particularly in the sciences, and the existence of critical thresholds on the size of department, below which useful research is not done, such specialisation makes good sense.

In addition to these general arguments, they add that the present funding system, through the Universities Grants Committee (UGC) and various research councils, works well in that it allows a large degree of autonomy to the universities. If a Scottish UGC were created, it would be a cosier affair than the British one, and 'inevitable incestuous relationships' would ensue. Equally dreaded would be the alternative of integration with the Scottish Educational Department (SED) responsible for the present Scottish educational system. Universities are, of necessity, elitist organisations and are afraid they would be swamped if included with other forms of education. In addition the track record of the SED is appalling. In spite of (or because of?) a new newmaths syllabus, there has been a catastrophic disintegration of mathematical education in Scotland. All Scottish university science departments complain bitterly of the mathematical illiteracy of incoming students—the educational elite, no less—who cannot cross-multiply fractions, know no trigonometry, and require remedial courses to teach them basic skills.

Dissenting view

These views contrast strongly with those of both the SNP and the Scottish Union of Students. At the same time as Gunn and Thomson argued their case, Professor R. S. Silver, an internationally renowned expert on desalination and a life-long nationalist, presented a dissenting view. On the 'internationalist' argument, he contends that other small countries such as Holland and Israel have solved the problem. An independent Scotland would be forced to look out more to the world. He repudiates the inevitability of incestuous relationships, arguing that if this were so, then conversely Russia and China would have the fairest support system in the world. Professor Silver also points out that estrangement will inevitably arise under the present proposals between the institutes of technology (controlled from Edinburgh) and the universities (controlled from London). As for the economy of scale argument, he thinks that 'big science' has already grown too big. It leads to massive engineering projects that are socially destructive and tie together the world's economies in an unstable manner, like a house of cards.

Since then the debate has descended to the letter columns of *The Scotsman* and the *THES*. John Hulbert, prospective SNP MP and former lecturer in bacteriology at the University of Dundee, has waded in with his analysis. He finds it 'sinister' that since 1939 the proportion of professors in Scotland with a Scottish education has dropped from 73% to 48%. Remembering that Scotland has only 10% of the UK population, most would find this evidence of continued parochialism, and his views an unhappy auguration of future SNP thinking on the 'internationalism' of Scottish universities.



Produce of Scotland:
Kelvin's mirror galvanometer

To Professor Malcolm Slesser of the energy studies department of Strathclyde University, who is also a nationalist, this idea of 'technological ecology' is also central. Engineering should be on an appropriate, human scale, and vast expensive projects should be eschewed. He, for one, would not complain if an independent Scotland could not build the Concorde. Silver and Slesser's argument is weakened by the fact that whatever the final scale of a project, the cost of developing even appropriate technologies is now vast, as exemplified by the programmes afoot in the USA, France and Japan to utilise solar power. Equally, almost no science is conceivable nowadays without a big computer. How big a computer could Scotland afford?

Professor Slesser thinks the real problem of Scotland stems from a lack of financial support for the development of appropriate new technology. He would like to see a revival of the technological entrepreneurship that characterised nineteenth century Scottish science, when a scientist such as Lord Kelvin could make a fortune (and get knighted) from his inventions. An investigation of government spending supports his view. Scotland does get a fair share of the UGC's and the research councils' university spending. The research councils also support special units: the MRC supports many all over the UK, and Scotland does rather well, with 11 of these. The MRC works on the human scale, however; the SRC, which is responsible for 'big science', believes it has to have its expensive equipment housed in central facilities, shared by the country as a whole. This argument is rather damaged by the fact that its major 'centre', consisting of the Rutherford Laboratory (particle physics), the Culham Laboratory (plasma physics), the National Computer Laboratory, the High Power Laser Facility and the Appleton Laboratory (space and atmospheric research), is very conveniently situated for London, but is well south of the academic centre of the UK, which is strongly weighted by the Northern and Scottish universities.

This is a mere peccadillo compared to the policy of the biggest research spender of the country, the Ministry of Defence. Of the 45 major research establishments listed by the MOD, apart from the lonely Naval Construction Research Establishment in Dunfermline, none are farther north than Baldock, 35 miles from London. As part of the devolution package the government has promised to move the MOD to Glasgow, which has a chronic unemployment problem. Every few weeks Glaswegians read in their newspapers, with a mixture of anger and amusement, the ideas of civil servants on the putative great trek North. The most common view seems to be that civilisation stops at Chingford and the Arctic Circle begins at Watford Gap. Hopefully, if the MOD is ever moved it will learn the error of its views and devolve some of its research establishments also.

Eternal drawback

What, then, about industrial research? While the government tries to encourage industry to the North with various short term benefits, there is an eternal drawback in that Scotland is at the periphery of Europe, and transport costs must always be high. This adds about £50 to the cost of a car made in Scotland rather than Birmingham. The more valuable the basic product, however, the less significant are these transport costs, and thus factories producing high technology items are least affected. This has been recognised by the American computer giants, and Honeywell, IBM, NCR, and Hewlett Packard all have factories in Scotland. They are just factories, however, and the best Scottish managerial and research personnel are siphoned off to England or abroad. Could the process be reversed by independence? This seems doubtful, in that a small Scotland is unlikely to be more successful at dealing with a high-technology multinational than the UK as a whole.

The lack of investment in new technology is also borne out by the experiences of the National Engineering Laboratory (NEL) at East Kilbride. Seven years ago the Rothschild committee recommended that the NEL should become less academic and liaise more with industry—should become, in effect, East Kilbride's answer to MIT. To a certain extent this has worked: of an annual budget of £10,000,000, industry now contributes £1,250,000, and of NEL's marketable ideas about half are taken up by local Scottish industry—eventually. John McAllen of NEL's industrial marketing unit is, however, depressed at the lack of interest that most of industry displays in trying to identify areas where new technology could be developed. Especially depressing is the tale of NEL's hydraulically driven dumper truck. In spite of a total lack of industrial interest NEL were convinced that this idea had promise, and developed it on their own. Their perseverance paid off, and eventually Carron Hydraulics of Falkirk took out a franchise on the invention. When the potential of the idea was proved, however, Carron Hydraulics was promptly taken over by the German Rexroth group.

The story of other countries reaping the rewards from Biritish inventions is now only too familiar. The worrying aspect of this case is that the invention was developed with government money specifically to benefit British industry; safeguards against subsequent foreign takeover should have been written in. The NEL is, nevertheless, of great importance to Scotland, both as an employer of scientific personnel and as a stimulus to industry. Its status in an independent Scotland would be very doubtful. ☐

USA

Maintaining momentum

Colin Norman reports from Washington on latest developments concerning recombinant DNA research

THE debate over the risks and benefits associated with recombinant DNA research, which has been raging in college campuses and city halls around the United States, suddenly picked up momentum in Washington last week. At one end of town, a public meeting sponsored by the National Academy of Sciences provided a forum for a clash of views on whether, and under what circumstances, such research should be permitted. At the other end of town, Representative Paul Rogers, chairman of the House health subcommittee, proposed legislation to regulate all recombinant DNA research in the United States. And in suburban Bethesda, a committee of officials from several government agencies met to try to draft a bill to be sponsored by the Carter Administration.

About the only clear message to emerge from this flurry of activity is that legislation to control recombinant DNA experiments throughout the United States is now inevitable, and that it would be welcomed even by many of the scientists who have long shivered at the thought of having an agency of the federal government regulate their research. But there was the glimmering of another message, at least in the Academy's public meeting. There emerged at the meeting vocal opposition to recombinant DNA research from non-scientists concerned about its potential long-term implications for human genetic engineering. Most of the debate so far has swirled around immediate health hazards, but it may slowly be shifted toward a discussion of the potential uses to which the research may ultimately be put.

First, the legislative developments. The National Institutes of Health (NIH) guidelines published last June formally apply only to recombinant DNA research supported by the federal government, and are not backed by any federal monitoring or enforcement mechanism. Industrial research is not formally regulated at present. Because of these apparent weaknesses some state and local governments are considering adopting their own enforceable regulations. Faced with that prospect, many scientists who once resisted federal legislation would now welcome it.

Whether scientists want it or not, however, legislation is definitely coming. For the past four months a task force of some 25 officials from federal agencies has been seeking ways to extend the NIH guidelines to cover all recombinant DNA research in the United States and to monitor compliance with the guidelines. The task force has recently concluded that no existing federal agency has the authority to carry out those roles, and that new legislation is therefore needed. The task force met last week to try to draft a bill for approval by the Secretary of Health, Education and

Welfare (HEW), who would then submit it to Congress. The task force didn't complete its work, however, and it will meet again this week. Its draft legislation is expected to recommend the establishment of a licencing scheme, administered by an agency of HEW (possibly the Center for Disease Control), for research involving recombinant DNA. In any case, the controls to be enforced on the research will be the NIH guidelines.

Meanwhile, Representative Paul Rogers has already got off the mark with a bill of his own. On 8 March, he made a speech in the House outlining some of the risks and benefits potentially arising from recombinant DNA research, and announced that he would introduce legislation to control the research and that his health subcommittee would hold public hearings on the measure on 15, 16 and 17 March. The following day, he introduced a bill co-sponsored by nine other members of his subcommittee.

The timing of the move was based on political considerations. The House Committee on Science, Research and Technology announced last week that it would hold a series of public hearings on recombinant DNA research during the last week of March, and Senator Kennedy's Senate health subcommittee is planning to hold hearings early in April, after the Administration's bill is introduced into Congress. Rogers didn't want to be in the position of seeming to react to events, so he had his staff draft a bill last week in record time.

When he introduced the bill, Rogers noted that "this proposal is intended to be a vehicle for discussion . . . and does not necessarily represent the views of its co-sponsors." Its chief provisions are as follows:

- It would require the Secretary of HEW to issue regulations governing recombinant DNA research which would be "no less stringent than the physical and biological containment requirements prescribed by the (NIH guidelines)". The regulations would also specify a role for institutional review committees.
- Any researcher wishing to conduct recombinant DNA experiments would have to obtain a licence from HEW, the application for which would describe the experiment and the conditions under which it would be performed. Licences would be valid for a maximum of two years.
- The bill would limit the number of high-containment (P4) facilities in the United States to ten centres.
- It would require the Secretary of HEW to publish in the *Federal Register* a description of projects for which licences have been granted, though trade secrets would be exempted from public disclosure.
- The Secretary would be empowered to inspect facilities in which recombinant DNA research is conducted, to ensure compliance with the regulations.
- Violations of the regulations would result in civil fines of $1,000 per day.
- The bill specifies that federal regulations would pre-empt local controls on recombinant DNA research, except that the Secretary could exempt local controls which are at least as strict as the federal regulations.
- Finally, it would establish an advisory committee to assist the Secretary in the granting of licences for recombinant DNA research.

Last month a bill establishing a licencing scheme and providing harsh penalties for violations of the regulations was introduced by Senator Dale Bumpers and Representative Richard Ottinger. Senator Kennedy may also draft a bill of his own. The final version to emerge will be a compromise between many different proposals, though particular attention should be paid to the Rogers bill if only because he is in a key position to steer his proposals through the House. A recent notable addition to Rogers' subcommittee staff is Burke Zimmer-

---

In an action which has so far attracted little public attention, a biologist at the University of California has been forced to destroy a large and painstakingly constructed clone bank because the clones were produced under conditions disallowed by the NIH guidelines governing recombinant DNA experiments. The incident has been described by some scientists as a good example of the way that the voluntary NIH guidelines can work to protect public health, but others have suggested that it underlines the need for more careful scrutiny of recombinant DNA research proposals before experiments are begun.

The research, carried out by John Carbon of the University of California at Santa Barbara, was performed between mid-1974 and mid-1976, a time when the NIH guidelines were under development. During most of that period, recombinant DNA research in the United States was governed by a loose set of safety guidelines drafted by a group of scientists which met early in 1975 at Asilomar, California. Those Asilomar guidelines did not rule out Carbon's experiments and even the final NIH guidelines, published on 23 June 1976, are a little ambiguous on the matter. Carbon thus did not infringe guidelines in force while he was conducting the experiments and he says he was unaware that his work lay outside the final NIH guidelines.

The work consisted essentially of constructing a large bank of clones of *E. coli* containing transplanted yeast genes and fruit fly genes. Taking the clone bank of yeast genes as an example, this, in short, is what Carbon did:—

He extracted the entire nuclear DNA from yeast cells and chopped it up into small fragments by mechanical shearing. He then spliced the yeast DNA fragments into bacterial plasmids and inserted the hybrid plasmids into *E. coli*. The next step was to culture the bacteria, growing several thousand distinct colonies, and each colony was then harvested separately. The collection of colonies constitutes a clone bank containing copies of DNA fragments, representing the entire yeast genome, spliced into plasmids inside living bacteria.

None of that would ordinarily be considered hazardous; indeed, the NIH guidelines specify that such manipulations with yeast genes require only low (P2) levels of physical containment. The problem, however, was that the *E. coli* which Carbon used to clone the hybrid plasmids also contained so-called fertility, or F, plasmids which promote the transfer of genetic information from one bacterial strain to another. This means that the hybrid plasmids contained in the *E. coli* might easily be transferred into other *E. coli* strains capable of surviving in the natural environment. In other words, use of bacteria containing F plasmids greatly lowers the barriers preventing escape of recombinant DNA molecules from the laboratory.

The scientific advantage of the system, however, is that it can be used for rapid identification of the transplanted genes, and it can also be used simply to test whether they are capable of being expressed in their new host. Essentially, Carbon transferred the plasmids from the *E. coli* bank into other strains and tested to see whether the properties of the new host were altered. In a paper published in the February issue of the *Proceedings of the National Academy of Sciences*, for example, Carbon and his co-workers report evidence that yeast genes are being expressed in their new hosts.

Last June, a couple of weeks before the NIH guidelines were published, Carbon presented the results of his work at a symposium on recombinant DNA held at Massachusetts Institutes of Technology, and his use of a system containing F plasmids was challenged on grounds of safety. Then, shortly after the NIH guidelines were issued, Carbon wrote to the NIH Recombinant DNA Advisory Committee for a ruling on whether or not his system is proscribed by the guidelines. The committee informed him last October that the guidelines should be interpreted as ruling out the use of *E. coli* containing F plasmids, and it instructed him to destroy his clone banks. Carbon was, however, given time to extract those plasmids which he wished to keep and transfer them to safer strains. He complied with the ruling last November.

Asked last week when he first had doubts about whether his experiments infringed the guidelines, Carbon said that "the realisation dawned on us slowly over the course of several weeks last spring". He said, however, that the guidelines do not specifically rule out use of his system, and he was therefore still uncertain about the propriety of his experiments even when the guidelines were issued. Other scientists queried last week said that although the guidelines are a little fuzzy on the matter, they thought that it was generally assumed that *E. coli* with F plasmids shouldn't be used. In any case, Carbon said that he is "willing to go along with the guidelines" and he destroyed more than 50,000 clones containing yeast genes and some 10,000 clones containing *Drosophila* genes.

man, a former representative of the Environmental Defense Fund who has long been active in seeking more public debate and stricter controls on recombinant DNA research.

While those legislative developments were taking place last week, the Academy's public meeting was in full, and sometimes noisy, swing at the other end of the Mall. Though the meeting essentially covered ground which has already been well trodden in college campuses and city halls around the country, it nevertheless generated considerable national attention and not a little friction.

Most of the high-temperature exchanges took place at the opening session, when a group called the Peoples' Business Commission (a reincarnation of the Peoples' Bicentennial Commission) staged a series of disruptions. Jeremy Rifkin, a spokesman for the group, was invited to address the meeting to air his grievances, and as he did so several of his supporters unfurled banners proclaiming their opposition to the research. Rifkin harangued the organisers of the meeting, claiming that the fact that it was supported financially by several drug companies rendered it suspect. In particular, Rifkin claimed that because the agenda was dominated by sessions concerned with potential health hazards from recombinant DNA research, it missed the central question of how the long-term implications of the research should be dealt with. Genetic engineering, he opined, is "the most important issue that society has to grapple with", and he told the researchers present that "you can't hide from the facts any more than the physicists who split the atom".

Although the interruptions and objections formed just a part of the meeting, Rifkin's objections did surface later in rather more subtle form, from speakers such as Jon Beckwith of Harvard, who noted that though there are still some barriers left to introducing genes into human cells, "these goals are not at all inconceivable and they may be achieved very rapidly". Beckwith announced that he has renounced use of recombinant DNA techniques, because "I do not wish to contribute to the development of a technology which I believe will have profound and harmful effects on this society".

Other speakers noted that one of the potential benefits often claimed for recombinant DNA is to help understand the causes of cancer. Such observations put the debate onto a different level from discussion of potential health hazards, and they could be much more difficult for scientists to grapple with. ☐

Sweet sorrow

AFTER more than six years of uncertainty, the Food and Drug Administration (FDA) last week decided to ban the artificial sweetener saccharin from general use in the United States. The action, which was prompted by clear evidence that the sweetener can cause bladder cancer in rats when fed to them in large quantities, immediately prompted shrill protests from the food industry, and it is sure to touch off a new round of attacks on the so-called Delaney Amendment which bans use of any food additive found to cause cancer in animals.

The evidence which finally sounded the death knell for saccharin came from a long-term feeding study sponsored by the Canadian government, preliminary results of which were made available to FDA officials on 7 March. Two days later, FDA and the Canadian Department of Health and Welfare announced that the sweetener would be banned both in Canada and the United States.

The full results of the study have not been published, but according to a summary made available by FDA, it turned up the following results. Out of 50 male and 50 female rats fed a diet containing 5% saccharin throughout their lives, three males and no females developed malignant bladder tumours. In addition, 50 male and 50 female offspring of those rats were also fed diets loaded with saccharin. The cancer incidence among them was more pronounced: 12 male and 2 female animals developed bladder tumours. Thus, 17 out of 200 test rats developed cancer compared with 2 out of 100 in a control group.

Until the full results are published, it is difficult to tell how good the study was. It has, however, long been regarded as the best test of saccharin yet undertaken, and FDA officials have been eagerly awaiting the results in the expectation that the study would finally settle the question of whether saccharin is or is not a carcinogen. They were impressed. The tests, according to Sherwin Gardner, the Acting FDA Commissioner, "show unequivocally that this substance can produce malignant bladder tumours in rats".

It has sometimes been suggested that the carcinogenic potential of saccharin may be caused not by the sweetener but by an impurity, orthotoluenesulphonamide (OTS). The Canadian tests, however, included a separate study of OTS and no carcinogenic effects were discovered. FDA was, therefore left with no choice but to ban saccharin from the market, an action which Gardner suggested was "based on science and on the requirements of Federal law". FDA hopes to publish details of the ban within a month, but it will allow those products already manufactured to be sold.

The ban could have considerable economic impact since saccharin is now the only artificial sweetener on the market in the United States. Cyclamates were banned in 1969, following evidence that they also cause bladder cancer in rats. And another sweetener, aspartame, was due to be approved by FDA a couple of years ago but approval was withdrawn following a discovery that the manufacturer of the substance submitted misleading test data. Once saccharin is removed from the market, there will be no non-nutritive sweetener for use by the burgeoning diet food industry. Some 5 million pounds of saccharin is now used in the United States, about three quarters of which goes into soda pop.

FDA's regulation of saccharin came under blistering attack last year in a study published by the General Accounting Office (GAO), an investigatory agency of the Congress. Noting that doubts about the safety of saccharin were raised in the early 1970s, particularly after a study published in 1971 indicated that the sweetener may be a potential carcinogen, GAO suggested that "extended use of a food additive, such as saccharin, whose safety has not been established and for which a carcinogenic potential has been raised, could expose the public to unnecessary risk".

FDA did, however, take some action against saccharin in 1972. It limited the amount of the sweetener which could be added to food and drink, and ordered that the substance should be used only in special dietary products. The latter requirement hasn't been rigorously enforced, however, for use of the sweetener has mushroomed, diet sodas are heavily promoted for general use, and saccharin is now found in products like toothpaste and pancake syrup.

With such a large volume of sales to protect, the food industry is expected to appeal the ban, through the courts if necessary. Some nutritionists are warning of the health consequences of an increased consumption of sugar.

Colin Norman

USSR

- The Soviet media have recently been devoting considerable attention to peaceful nuclear explosions (PNE). Although the Soviet PNE programme dates back to 1965, so far explosions have been carried out without publicity. Recently, however, a number of Soviet press and radio reports have extolled the use of PNE in digging the Pechora–Volga canal, and the construction of water and underground gas storage reservoirs. An interesting feature of this campaign is that all three major broadcasts on PNE achievements were in English (one being in the African service), and therefore aimed at the outside world; in one case, the contents of the broadcast was then issued in a *Novosti* press release.

Soviet experts do not share American doubts on the commercial viability of PNE, and are eager for the ratification of the PNE agreement, already initialled in Moscow and awaiting ratification by Washington, which would ensure mutual on-site inspection and instrumentation rights. Although the Soviet delegate to the Geneva disarmament talks, Mr V. A. Likhachev, recently called for a total cessation of all nuclear weapon tests, there are clear indications that the Soviet Union would not be willing to accept a ban or a moratorium on PNE. The recent burst of publicity may well be intended to make the Soviet attitude clear to those governments which would favour a total ban on all nuclear explosions.

- Conservation of the country's resources, including energy, is an important feature of the present Five-Year Plan. Targets include savings of 14–16% ferrous metal in machine construction, 5–7% metal, 5–6% cement and 12–14% timber in building, and 5% electrical and thermal energy and 8% petrol and diesel fuel.

This winter, inspections and surveys have been made in many parts of the Soviet Union to monitor fuel consumption. A supporting campaign in the media, commending the economical consumers and rebuking the wasteful, is aimed at all levels of the community—from the electrical generating industry, which last December cut its specific consumption by 2 g fuel per kW-hour (saving some 1.5 million tonnes of coal), to the workers of Vladivostok, who by their "thousands of valuable suggestions" have allowed some 13 million kW of electricity and 49,000 tonnes of rated fuel to be saved.

Particular criticism has been directed at the Ministry of Fuel and Power (for slowness in converting to more efficient boilers), at the metallurgical industry (for poor use of recycled resources), and the Ministry of Construction of the Oil and Fuel Industries (for delays in constructing gas refineries, so that "thousands of millions of cubic metres of gas" have had to be burned off into the atmosphere) and various local authorities (for lighting and heating empty buildings, using expensive fuel from elsewhere rather than cheap local coal, peat or wood).

- Three Moscow refusniks, the cyberneticist Aleksandr Lerner and Vladimir Slepak and Anatolii Shcharanskii, both engineers, are attempting to bring a libel suit against Dr Senya Lipavskii and the editor of the government newspaper *Izvestiya*. Dr Lipavskii, a former associate of the refusniks, is the author of an 'open letter' published in *Izvestiya* alleging that a number of the prominent Jewish activists, including the three men, are CIA agents.

Such denunciations have in the past always been followed by criminal proceedings, and it would be unprecedented if no action were to be taken in this case. Shcharanskii, who often acts as unofficial spokesman for the group, has already had all his documents except his internal passport confiscated. To try to refute the expected charges, Lerner, Slepak, and Shcharanskii have attempted to initiate proceedings for libel, although various bureaucratic barriers are being placed in their way.

Together with the economist Ida Nudel and Dina Beilina, an engineer, they have also written a letter to President Carter, asking him to do something "constructive" to ease the situation. Although the text of the letter has not been released by the signatories, it seems that they would urge a firm but 'soft' response. The letter of Academician Sakharov to President Carter last January, which called on the President to "raise your voice" against human rights violations in the Soviet Union, was interpreted by the Soviet authorities as a provocation to cold war, as was the recent meeting of the President with Vladimir Bukovskii. Lerner and his friends, it would seem, are unwilling that their case should be used to undermine the very real benefits of détente.

- The new Soviet 200-mile fishing zone, which came into force on 1 March, has inaugurated a new era in Japanese–Soviet fishing relations. So said the Japanese Minister of Agriculture and Fisheries, Zenko Suzuki, during four days of stiff negotiation in Moscow at the turn of the month. By the end of the talks it was clear that the new era was not to be one of immediate agreement; indeed, Mr Suzuki and the Soviet Minister of Fisheries, Aleksandr Ishkov, could not even agree on a joint communiqué, and the talks ended in a formal exchange of notes.

During the talks Mr Suzuki stated that for constitutional reasons Japan could not accept certain provisions of the decree establishing the Soviet zone. His concluding note to Ishkov stated that Japan would also be establishing a 200-mile zone in the near future. This will encroach upon the new Soviet zone on the west coast of Japan and in the region of the La Pérouse and Kunasharskii straits. In spite of these diplomatic difficulties, however, certain practical conclusions were reached, pending the interim pact (expected by 31 March). Japanese fishing vessels will be permitted to operate within the new Soviet zone, but may not engage in herring or salmon fishing. Negotiations are to be continued towards a long term agreement.

A similar position, but with the Soviet Union in the role of the applicant seeking to enter an exclusive zone, has arisen in the fisheries talks between the Soviet Union and the EEC. The first round of talks, in February, were hailed as a diplomatic breakthrough; the second round failed this month to produce the "mutually acceptable results" which Mr Ishkov had hoped for. Since both sides realise that they are at present too far apart to reach an early agreement, the talks have been postponed until 19 April.

Vera Rich

BRITAIN

• Figures on graduate employment from three of Britain's top universities don't conform with everyone's predilections when it comes to science graduates.

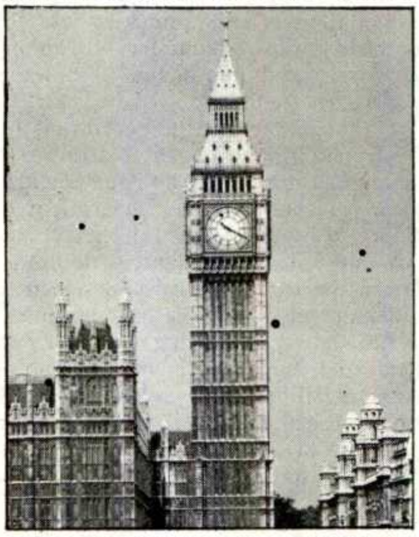
The view heard these days is that graduates, especially from Oxford, Cambridge and London, are likely to go into the types of employment which served Empire well but which are of less obvious use in the modern industrial era. The suggestion is that they are most likely to go into central and local government or teaching when they aren't busy becoming perpetual students by doing post-graduate study. Otherwise they are likely to be joining the professions—becoming accountants or solicitors, moving into banking or insurance—or joining the media by going into journalism, broadcasting or publishing. What they aren't doing, the argument goes, is helping to boost Britain's long term economic potential by going into directly productive employment in industry.

Figures giving details of employment of 1976 science graduates from Oxford, Cambridge and London do not appear to bear these assertions out. Even after making allowances for difficulties in interpreting the statistics in precisely comparable terms, the indications are that Britain's graduates in the pure sciences, if they are not going into research, are most likely to go into industry.

That they are likely to go on to further study is strongly indicated by the figures for both Oxford and Cambridge, where a high proportion, around one-third, of the men science graduates from both places opted for this course. But of the 390 Oxford men science graduates who worked in other fields in Britain after graduating, 155 went into industry; and of the 193 Cambridge science graduates, 88 did so. For London, the figure was 209 out of 497.

For the public service and education, moreover, the figures are not high. Just 20 out of 193 from Cambridge went into the public service, and 23 directly or indirectly into teaching. The comparable figures from Oxford are 65 and 44 (out of 390) and from London 75 and 68 (out of 497). Similar tendencies are apparent in figures for accountancy (32, 58, 47) and for banking and insurance (7, not available, and 34). And from all three universities together a total of only 21 men went into the media or elected to become solicitors.

What makes the figures even more interesting is that similar trends, though less marked, can be identified for arts and social studies graduates. At the other end of the university machine, meanwhile, the number of entrants into tertiary education who go into science and engineering remains a prominent topic, not least, it seems, because the facts are disputed. At the beginning of the month the Education and Science Secretary, Mrs Shirley Williams, described the need to attract students into science and engineering courses as "urgent". Her department is at the moment investigating whether to introduce a form of scholarship to encourage sixth-formers to specialise in science and engineering. But the Vice-Chancellor of Durham has warned of a glut of engineers, and the London University Institute of Education is saying the shortage of engineers and scientists is a myth.



• The state of Britain's manufacturing industry is an issue unlikely to be superseded in importance by questions about her agriculture, itself an industry. At the end of last month, though, it was announced that the country's standing Royal Commission on Environmental Pollution, now under the chairmanship of Professor Hans Kornberg, was to examine how the trend towards large livestock units and the greater use of fertilisers and pesticides posed an increased risk of pollution. The Commission also wants to examine the vulnerability of agriculture to industrial pollution.

Among the bodies which might show an interest is the Nature Conservancy Council (NCC). A report it published last week suggests that financial assistance and advice on conservation should be given to farmers if the problems their farming practices create for wildlife are to be alleviated. The report estimates that if all farms were to be totally modernised, about 80% of the bird and 95% of the butterfly species would be lost from the farmed landscape. The NCC wants a policy of wise land use which provides for the conservation of wildlife as well as increased food production.

Increased food production was just one of the points broached last week by Professor John Bowman, the Director of the Centre for Agricultural Strategy at the University of Reading, when he spoke about an agriculture strategy for Britain. He talked of food consumption ("comfortably in excess of or equivalent to recommended minimum levels for normal life"), of changing eating habits to help feed others less fortunate (that had "little to commend it"), curtailing animal production, because of worries about its cruelty or its energy inefficiency ("it is more justifiable to argue for the modification of production systems so they are based more on feed inputs of no direct use to man"), and justifying protectionist policies in terms of security (there are sound arguments for achieving security "through an increase in the world trade of all commodities, not least of which are food commodities").

He also presented the preliminary findings from the Centre's own model of the UK agricultural economy. Its projections for a future with a higher degree of self-sufficiency and lower import costs indicated broadly that, even allowing for modifications in diet, meat production was expected to contract, the dairy sector, sugar beet and oilseed rape were expected to expand, and the cereal acreage would remain largely unchanged. But technical and economic efficiency were unlikely to be the only objectives of public policy; justice, equity and security could take precedence.

• The University of Bradford's Disaster Research Unit, which was established in December 1973 and has just three members, is now fighting for its survival. When the initial period of three years for which the unit was financed came to an end late last year, the university (which provided the funds along with the Leverhulme Trust and the Ministry of Overseas Development) agreed to finance a further year pending the outcome of a review. This showed that with the cuts it faced the university could not support the unit. Now the unit has stopped work while its members ask the government, international agencies and trusts for more funds.

Chris Sherwell

Potential energy

Developments on Britain's energy front are continuing apace. Chris Sherwell reports

GAS, coal, oil and nuclear power have all featured in the past week's energy developments. At the risk of involving the Cabinet and angering the unions, the Energy Secretary, Mr Anthony Wedgwood Benn, is proposing to overrule the Price Commission's rejection of the British Gas Corporation's (BGC) application for a price rise. The rise, effective next month, will boost BGC revenues by 10% and is part of the attempt to rationalise Britain's energy industries.

The development came after news that additional coal resources amounting to more than 200 million tonnes have been discovered in Warwickshire. The seams compare with the Selby and Vale of Belvoir fields, and are the result of the National Coal Board's exploration programme. A new £50 million three-year programme is due to start soon, and more discoveries are expected.

But not everything is rosy. Coal prices are also going up next month; NCB projections of output until the 1980s under its Plan for Coal show that exploitation of new mines is beset by problems in obtaining planning approval; and productivity shows a downward trend.

On the oil front the important matter of depletion policy in the North Sea is attracting attention The issue emerged clearly recently in the Department of Energy's broad review for the NEDC. An annex stated that large-scale licencing in the early 1970s was designed to build up an exportable surplus in the 1980s; delays in starting work on new fields and "slippage" in the build-up of commercial fields, however, had "somewhat eroded the level of production expected in the early 1980s and therefore the export surplus".

Last week a slightly more optimistic prognosis for the export surplus was produced by a policy adviser to the British Petroleum Board, who counselled against a strict depletion policy designed to prolong the period of self-sufficiency. The issue looks like becoming increasingly important as the time for critical nuclear power decisions draws closer.

Arguably the most important of those decisions concerns the fast breeder reactor. One report this week says there are suggestions for a supervisory board, representing all concerned interests, to manage the project; an executive team of experts would report to it. The Prototype Fast Reactor at Dounreay, due to be shut down recently for a ten-week overhaul and for refuelling, will meanwhile take over the role of the small experimental reactor, which will be closed in a ceremony next week after some 17 years of service In the reprocessing field Mr Benn's intervention last weekend has seen the end of the six-week industrial dispute at the British Nuclear Fuels plant at Windscale ☐

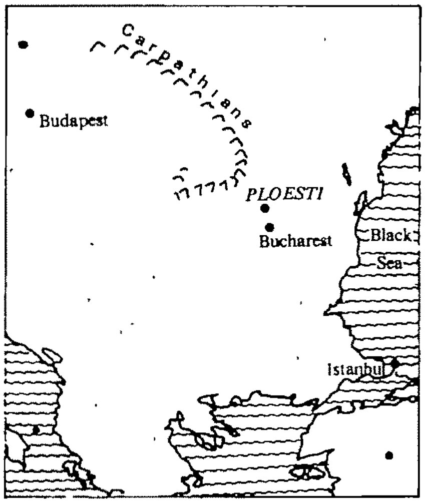
Quake patterns

BACKGROUNDER

EARTHQUAKES in Romania have many unusual features to them, not least a somewhat erratic occurrence rate. The recent quake of magnitude greater than 7 near Ploesti, which has caused such widespread damage and the loss of over a thousand lives, seems to conform to the pattern.

There is regular seismic activity in a band running down the east coast of the Adriatic, through the Aegean Sea and off into Northern Turkey, but further north, activity is rare, suggesting that the major active plate boundaries run well south of Romania. There is, however, a little activity along the north coast of the Black Sea, and a small isolated pocket of Romanian quakes lies along the continuation of this line at the southern most limit of the Carpathian mountains. These quakes are at a depth of 50 to 150 km and lie in a vertical slab (*Nature* **228**, 1176–8 (1970)); the slab is probably the relic of a small segment of ocean that was overridden millions of years ago but is still out of equilibrium with its surroundings. The earthquakes would then result from the release of stress as the slab settled.

Since the recent quake there have been several attempts to discern patterns in the times of occurrence of Romanian earthquakes Rarely can credence be attached to such statements which have been made on the basis of a rapidly compiled historic compilation. Although the catalogues back to about 1900 are quite good for large earthquakes, the estimate of magnitude for many of these events leaves a lot to be desired; any analysis which then looks at the statistics of events above a certain magnitude is bound to be using shaky premises.



Even so, the suggestion emerging from the US Geological Survey (and regrettably inflated into an ambassadorial message) is of interest. It has been noticed that six of the eight quakes since 1900 which the Survey regard as large have occurred in pairs, separated by a month or so. This is quite an unusual observation for earthquakes, and the prospect of a second large quake cannot be discounted. Prediction techniques based on rock dilatation that are beginning to emerge as important for shallow quakes seem difficult if not impossible to apply at present to events as deep as the Romanian quakes.

The earthquake was felt over a very wide area—Moscow, a thousand miles away, was shaken slightly. This had been noted for previous shocks and probably arises from a combination of two factors. First, an earthquake at depth, away from the near surface inhomogeneities, irradiates a larger area than does a shallow shock. And second, there is probably very little absorption of elastic waves crossing an old, stable region such as Western Russia.

Legal proceedings, it is reported, are to be brought against architects whose modern buildings collapsed in the quake. There is a certain amount of sense in this. An earthquake of comparable dimensions occurred in 1940 and was destructive; it seems that in some cases appropriate lessons have not been learnt. Earthquake-proofing of buildings is by no means an impossibly expensive task, and is done routinely in California and Japan, with great success Maybe one of the good things to emerge from the disaster will be a greater insistence on building to safer standards.

IN BRIEF

Science budget breakdown

The Department of Education and Science (DES) was unable to comment this week on a report in *THES* detailing the breakdown of the Science Budget for 1977–78. The figures have yet to be agreed formally with the Treasury and passed by the House of Commons.

The Science Research Council's budget is believed to break down as follows: nuclear physics, including the CERN subscription, £43.3 million; astronomy, space and radio, £27.6 million; science, £23.3 million; engineering, £14.5 million. Figures for the other research councils are reported to be as follows: MRC, £42.3 million; NERC, £29.5 million; ARC, £20.4 million; SSRC, £14.5 million. The size of the overall budget was foreshadowed in the recent expenditure White Paper.

NASA change

James C. Fletcher, who has been head of the National Aeronautics and Space Administration (NASA) for the past six years, is being replaced, another casualty of the Carter Administration. He announced last week that he will leave on 1 May. The post is a Presidential appointment and Fletcher consequently submitted a pro-forma resignation to President Carter along with other holdovers from the Ford Administration, but it was no secret that he wanted to be kept on. No reason has been given for accepting his resignation and no replacement has been announced.

UN conference opens

Experts from some 150 countries were Argentina, this week for the opening of the two-week UN Water Conference. The major item for discussion highlighted last year's Habitat conference in Vancouver: providing clean and safe water supplies to residents in urban and rural areas as soon as possible. Also on the agenda: pollution control, conservation of water resources, management of shared lake and river resources, water as a disease carrier.

Psychiatrist's death

The death has been recorded of Professor Daniil Lunts, head of the fourth section (political) of the Serbskii Institute of Forensic Psychiatry.

Last weekend a young paramedic, Aleksandr Podrabeinnik, who has collected details of over 200 cases of sane mental hospital internees in the Soviet Union, had his flat searched and papers confiscated.

Monster debate

THOMAS H. JUKES

THE debate on recombinant DNA is so far a tribute to the power of the human imagination rather than an acknowledgment of actual results obtained in laboratories. Most of the stronger statements seem to be made by people who are not trained in biology. However, some good ammunition has been provided by prominent scientists. For example, Robert Sinsheimer recently advanced the possibility that DNA from *Clostridium botulinum* might be used by a 'terrorist group' to transform *E. coli* into producing botulinus toxin. Obviously, such a group will not apply for a permit from the National Institutes of Health.

The environmentalist societies have reacted promptly and swiftly to the issue. The decision was easy, because in matters of science and technology, especially new ones, they are guided by the principle stated by Groucho Marx in the 1930s:

> I don't know what you're going to say
> It makes no difference anyway
> Whatever it is, I'm against it!

Some of the busiest recombinant DNA laboratories are in our own digestive tracts, where the transducing phages, episomes and Hfr strains have been switching DNA around ever since the days of early evolutionary history. Knowledge of this should (but won't) have a calming effect on those who believe that recombination is a recent invention of maniacal molecular biologists.

I am impressed above all by the fact that nature buries her countless numbers of mistakes. The two-headed calf does not survive. Nor does nature help us in our genetic manipulations. The most productive strains of our major crop plants would rapidly vanish without human protection and nurture. Maize would be the first to disappear. It is true that there are deadly pathogenic micro-organisms in our midst but the number of species of these is comparatively small. They are the product of millions of years of commensal evolution with their hosts. The thought that we could slap new ones together in the lab and that they would be viable enough to run riot seems faintly ridiculous.

Even such an apparently obvious advantage as antibiotic resistance does not easily persist. Some years ago I participated in launching an experiment that spread widely; the addition of antibiotics to the feed of domestic livestock. Although this has recently been criticised and scrutinised, the strange fact remains that it 'still works', when by all predictions the spread of resistant strains should long ago have made the procedure useless. This is especially so because resistance in enteric bacteria can spread by DNA recombination. I presume the wild, susceptible strains must tend to overgrow the resistant ones.

Public understanding of recombinant DNA is greatly aided by previous conditioning to science fiction. A long-time staple subject for cartoonists in popular magazines is typified by a picture showing 'mad scientists' in a laboratory where enormous rats are emerging from a flask, captioned 'Something Went Wrong'. This theme, almost to the letter, was used in a recent cartoon, and, to make the point absolutely clear, the scientists wore lab-coats labelled 'MIT'.

So far, the one predictable result of 'recombinant DNA research,' even the research that hasn't been done, is a bureaucratic explosion of paperwork. Any mention of DNA in a research grant proposal presses the alarm button, and a large package of questionnaires arrives in the mail. We can probably look forward to a new National Institute for Regulating Recombination, and even to its counterparts in state and local governments. Also, the term 'recombinant DNA' rolls trippingly from the tongue, and politicians know a vote-getting issue when they see one.

correspondence

The toxicity of plutonium

SIR,—We wish to comment on three recent publications, all originating in the United Kingdom, which have discussed the radiotoxicity of inhaled, insoluble plutonium compounds. In a recent article in *Nature*, Thorne and Vennart[1] concluded that the previously accepted value for the maximum permissible annual intake (MPAI) of such compounds may be too high by a factor of about five. A similar conclusion had previously been reached in a Medical Research Council report[2], and in a report[3] by the Royal Commission on Environmental Pollution. Our main purpose here is to point out:

- that the proposed changes in the MPAI and in the closely-related maximum permissible air concentration (mpc) do not necessarily imply any change in the present procedures for assessing doses and risks in situations where persons have known amounts of insoluble plutonium in their lungs;
- that although the article in *Nature* and the MRC report come to broadly the same final conclusions, the reasons for the conclusions are significantly different; and that the uncertainties in the calculations, to which attention is drawn in both papers, are as large as the proposed reduction factor;
- that the observed behaviour of the technologically-important high fired plutonium oxide in people who have accidentally inhaled such material is significantly different from the behaviour predicted from the lung model assumed in recent MPAI calculations.

Maximum permissible annual intake. Thorne and Vennart stress that the MPAI which they derive is intended for planning purposes[1]. We believe that most facilities in which plutonium oxide is handled are planned on the basis that there will be virtually no chronic exposure, and that this is also true in operational practice; hence the precise value of the MPAI (or the mpc) is somewhat irrelevant. However, exposures do occur from time to time, due to unplanned but identified incidents which usually cause the exposure of one or two individuals to quite high concentrations for a short time. In such situations, we believe that it is good practice to make the best estimates of intake, dose and risk to those specific individuals on the basis of measurements taken on them, with no reference to the concepts of MPAI (or mpc). In fact, such a procedure is explicitly recommended[4] in *ICRP Publication 19* on the page following the one on which they describe the model used in *Nature* and the MRC report.

Uncertainties in the MPAI. Although the *Nature* article and the MRC report both conclude that a reduction in the MPAI of the order of a factor of five is to be recommended, the two sets of calculations show significant differences. For example, the respective estimates of risk of bone cancer differ by more than a factor of five and the risks of lung cancer by more than a factor of three. On reading the respective texts it is obvious where the differences lie (in the relative importance of the respiratory lymph nodes, in the quality factor for alpha particles and in the calculations of dose to the bone). Both publications acknowledge that the estimates of 'nominal risk' are open to criticism and that the data on which they are based can be interpreted in several ways. It is an unfortunate fact that such qualifications are often disregarded by those who draw conclusions from the final tabulated presentation.

The maximum permissible lung burden (MPLB). In the summary of conclusions (paragraph 526.2) of its sixth report, the Royal Commission on Environmental Pollution[3] claimed that a reduction by a factor of five in the MPLB is already practised. This statement appears to have resulted from a misunderstanding; we believe that their statement was intended to apply to the MPAI. The conclusion stated in paragraph 526.2 does not follow from the section of the report in which the matter is discussed (i.e. paragraph 77). Neither the MRC report nor the *Nature* article explicitly suggested a reduction in the MPLB, and in our view, no such reduction is required in the case of high fired plutonium oxide.

ICRP lung model. As explained above, all of the recent calculations have been based on the use of the lung model of *ICRP Publication 19*. The parameters given in the model were derived mainly from animal data, and presumably represent at best the mean or median values of a number of widely differing experimental values. Consequently, as explained in the associated text of the ICRP publication, the model can only be used for deriving general exposure limits; to evaluate a specific exposure situation one should choose the data most relevant to that particular situation. Measurements made on a substantial number of individuals[5,6], who had inhaled high fired plutonium oxide, show that the material initially deposited in the lung is removed much more rapidly than the ICRP model would suggest for what it calls a Class Y material. Moreover, experience here at Winfrith (to be published) has shown that the amount of material transferred from the lung to other parts of the body is also significantly less than the model would suggest; perhaps this is a consequence of the more rapid removal to which we have referred. As a consequence of these two factors, if risk estimates are made for those people who have inhaled high fired plutonium oxide, they are found to be a factor of about 5 lower than the risk estimates based on the use of the lung model, i.e. they are no higher than was previously supposed.

Discussion. We feel that the methods which have been used to derive new values for the MPAI are unduly pessimistic for high-fired plutonium oxide. That fact in itself does not worry us unduly. What does worry us is that people may be tempted to conclude, by the use of the same lung model, that in every case in which a person inhales insoluble plutonium, the risks to bone and liver are comparable to those of lung; and hence to conclude that the MPLB should be reduced. We believe that in the case of high fired plutonium oxide, the previously established idea that the lung is the critical organ remains substantially correct.

Marburg and Ebola: viruses in search of a relation

from David I. H. Simpson and Arie J. Zuckerman

IN the second half of 1976 two severe epidemics of haemorrhagic fever broke out in Sudan and Zaire. The virus responsible, provisionally named Ebola virus, proved to be structurally similar but antigenically different from that of Marburg disease, and three recent reports in *The Lancet* give details of its isolation and preliminary characterisation.

Marburg virus

Marburg virus disease, popularly but incorrectly named 'green monkey' disease, is a severe distinctive haemorrhagic febrile illness of man, first described in 1967 when thirty-one cases of illness with seven deaths in Germany and Yugoslavia were traced to direct contact with blood, organs or tissue cell cultures from a batch of African green monkeys (*Cercopithicus aethiops*), which had been trapped in Uganda. Several secondary cases occurred in hospital personnel by contact with the blood of patients, and one further case was apparently transmitted by sexual intercourse 83 days after the initial illness. The case fatality rate was 29% for the primary cases, but there were no deaths in the six secondary cases. It soon became apparent that this was a previously unrecognised disease caused by an infectious agent probably new to medical science.

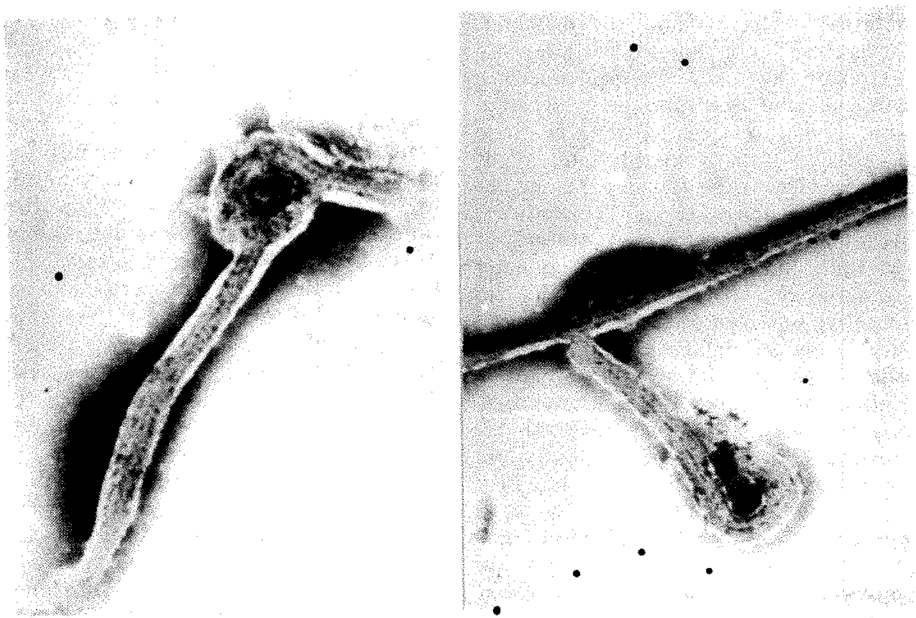
The possible origin of the infection has been investigated since the 1967 outbreak. Complement fixing antibodies to the Marburg virus were reported from a laboratory in the USA in many African monkeys, but conflicting results were obtained in other surveys and it appeared that the antigen used in the USA was not entirely specific. Furthermore, before 1967 many thousands of monkeys had been handled in biomedical laboratories without such outbreaks, and in addition experimental infection of monkeys proved uniformly fatal. The natural cycle of transmission of the virus in various species of animals and the origin of the infection are still under intensive investigation.

The first recognised outbreak of the disease in Africa and the first since the original outbreak, occurred in South Africa in February, 1975. The primary case was a young Australian man who had hitch-hiked through Rhodesia. He died in a Johannesburg hospital and shortly afterwards his girl travelling companion and one of the nurses who had cared for him fell ill with the same disease. The girls recovered. Virological studies showed that this outbreak was caused by the Marburg virus.

As in the original Marburg outbreak, when virus was isolated from seminal fluid 83 days after the onset of illness, evidence was obtained that the virus can persist in the body for at least 2–9 months after the initial infection. In the Johannesburg episode, virus was cultured after infection of the eye from fluid aspirated from the anterior chamber of the eye 80 days after the onset of the illness (Gear *et al. Brit. med. J.* **4**, 489; 1975).

Ebola virus

Three recently published papers by Pattyn, Bowen and Johnson and their colleagues (*Lancet* **i**, 569–574; 1977) now give details of the isolation and preliminary characterisation of the virus responsible for two severe and almost simultaneous epidemic outbreaks of haemorrhagic fever in the equatorial provinces of Sudan and Zaire in the second half of 1976. The isolates were found to be structurally indistinguishable from strains of Marburg virus



Electron micrograph of the Zaire prototype strain of Ebola virus (courtesy of E. T. W. Bowen and W. J. Harris).

isolated in Germany in 1967 (Siegert *et al. Dtsch. med. Wschr.* **92,** 2341; 1967) and South Africa in 1975, but antigenically the Sudanese and Zaire isolates although identical to each other were quite distinct from Marburg. The prototype of these new strains has been named Ebola, after a small river in Zaire which flows north of Yambuku, the village of origin of the patient from whom the first isolate of the virus was obtained. Experimental studies in laboratory animals (E. T. W. Bowen, unpublished results) confirm the antigenic differences since previous immunity to Marburg virus does not protect against subsequent infection with Ebola virus and *vice versa.*

Morphology

Marburg and Ebola viruses show no antigenic relationship to any other animal virus and morphologically they belong to no known virus group. Marburg virus contains RNA, has an outer envelope containing lipid, and is ether sensitive. Both viruses are formed by budding through cell membranes and it has been suggested (Siegert *et al. op. cit.*) that Marburg resembles members of the rhabdovirus group. However, the size of the central core and the cross-sectional structure differs from that of rhabdoviruses.

Two principal structural forms of Marburg virus have been described (Almeida *et al. Marburg Virus Disease* (eds Martini & Siegert) 85, Springer-Verlag, Berlin, 1971): an elongated filamentous or sinuous form, which could be described as tubular; and a circular form in the shape of a 'doughnut' or torus.

Both forms have an overall diameter of 70–100 nm excluding projections on the outer surface and contain an internal helix 40 nm in diameter. Several of the sinuous particles are extremely long, often several microns. Almeida and her colleagues suggested that as mature virus particles give rise to circular torus forms Marburg might be regarded as the founder member of a group known as the Toroviruses. However the predominant forms of Marburg and Ebola most frequently seen in the electron microscope in negatively stained preparations (Figure) are long tubular structures and since they contain RNA perhaps a better name might be Tuburnaviruses, a name suggested at an informal discussion between K. M. Johnson and ourselves. Geographical names for diseases or their causes are also to be discouraged since these may be misleading, implying as they do an unusual association with a particular country or town, and may then lend a sinister conotation to the area, as in the case of Lassa, a town in North-Eastern Nigeria and Marburg, a University town in Germany.

Epidemiology

It has now been generally accepted that monkeys are not the natural reservoirs of Marburg infection. Intensive epidemiological investigations in Southern Africa following the three cases in Johannesburg in 1975 failed to provide many clues to the natural maintenance host of the virus. Similar investigations in Sudan and Zaire have not yet uncovered the reservoir of Ebola virus. The Zaire and Sudan outbreaks involved well over 500 cases and at least 350 deaths. The illness was marked by a sudden onset of severe headache, fever, muscle pains and prostration, quickly followed by profuse diarrhoea and vomiting and later in many severe cases by dramatic haemorrhages, and closely resembled the illness described in Germany in 1967 and in South Africa in 1975. The typical skin rash so common in white-skinned patients was not so distinct in black skins. In each outbreak, be it Marburg or Ebola fever, attendant medical and/or nursing staff became infected often with disastrous results. Two hospitals in Zaire and Sudan were brought to a standstill; in one hospital in Sudan 76 staff became ill and 41 of them died. Direct human-to-human transmission was responsible for all the secondary infections usually brought about through close and prolonged contact with sick patients and particularly through contact with patients' blood.

The fact that Marburg and Ebola viruses once they have been transmitted to man through this contact with an unknown reservoir host can adapt themselves to direct man-to-man transmission means that these severe infections could easily be introduced from their country of origin to countries where the natural host does not exist. Hence the international concern over these infections and others such as Lassa fever. It is therefore all the more important that detailed epidemiological investigations are carried out without delay. □

Trypanosome antigens

from F. E. G. Cox

INFECTIONS with African trypanosomes are long-lived and are characterised by waves of parasitaemia in which the parasites seen in the blood at any one time differ antigenically from those of preceding waves. This antigenic variation is thought to be responsible for the prolonged infections in what ought to be immune hosts because, although the hosts make antibody to each antigenic variant, they are foiled when the antigens of the trypanosomes change and each becomes effectively another parasite. The mechanisms of antigenic variations are interesting from both theoretical and practical viewpoints and over the past few years three important questions have been asked. First, are variant antigens situated in the surface coat, second, if so, are they produced by the trypanosomes or are they accretions of host serum proteins and, third, do all trypanosomes carry a range of variant antigens or do certain individuals possess one kind of antigen and others a different kind? In the case of *Trypanosoma brucei* these questions have now been satisfactorily answered.

It is now known that the variant antigen actually constitutes the majority of the surface coat of the trypanosome (Cross *Parasitology* **71,** 393; 1975; Cross & Johnson *Biochemistry of Parasites and Host Parasite Relationships* (ed. van den Bossche, H.) 413; 1976) and that it is a glycoprotein consisting of a single polypeptide chain of molecular weight 65,000. The different variants are not simply minor modifications of a basic type because when the amino acid sequences of related variants are analysed they are found to be completely different from one another (Bridgen, Cross & Bridgen *Nature* **263,** 613; 1976). So the answer to the first question is that not only are the variant antigens associated with the surface coat, they actually form much of it and furthermore the successive variants represent structurally dissimilar polypeptide chains. Could these have come from the host serum? A recent paper by Taylor and Cross (*Parasitology* **74,** 47; 1977) proves that they do not. When trypanosomes are maintained *in vitro* in the absence of host material variant antigens are still synthesised and incorporated into the surface coat. This confirms the original hypothesis of Vickerman (*J. Cell Sci.* **5,** 163; 1969) and refutes the suggestion by Desewitz (*Immunity to Parasitic Animals* **2,** (eds Jackson, G. J. *et al.*) 551; 1970) that the variant antigen is assimilated from the host.

Trypanosomes revert to a basic antigenic type after they pass through the tsetse-fly vector and the subsequent variants appear in a recognisable sequence. This occurs even in infections initiated with single parasites (clones) and this has been interpreted as meaning that trypanosomes do not exist as mixed populations with different individuals expressing different variants but actually continually change their antigens. However, experiments by van Miervenne *et al.* (*Annl Soc. belge. Med. trop* **55**, 1, 55, 25; 1976), using a fluorescent antibody technique to identify particular variants, have shown that clones rapidly become antigenically heterogeneous and that in every population there are a few individuals that do not bear the antigen characteristic of the population. These individuals are at an advantage when the immune response to the predominant antigen begins to become effective but are in their turn destroyed as they become dominant and have to give way to yet other variants.

Cross and his coworkers suggest that trypanosomes express a gene for and synthesise a single variant antigen at a time. Over evolutionary time a number of genes each coding for a particular variant have emerged by mutation, been selected for and have been accumulated giving the trypanosomes of the present time a vast repertoire of variants which they need to survive in their mammalian hosts. None of the available evidence contradicts this hypothesis and the next questions must be how the antigen switch is brought about and, when this is known, how it can be stopped. To those living and trying to raise cattle in the tsetse belt of Africa this is not just an academic question. ☐

Prenatal detection of thalassaemia

from Sue Malcolm

THE various inherited haemoglobin disorders which collectively go under the name of thalassaemia are the most serious genetic diseases in many parts of the world. So the successful prenatal diagnosis of both the α and β thalassaemias marks a significant advance in their prevention.

α thalassaemia (in which no α globin chains are produced) is now known to be caused by the deletion of the DNA coding for the α chain (Ottolenghi *et al. Nature* **251**, 389; 1974; Taylor *et al. Nature* **251**, 392; 1974), and Y. W. Kan and colleagues in San Francisco have now devised a method of determining whether the α globin genes are present in foetal DNA (*New Engl. J. Med.* **295**, 1165; 1976).

The foetal DNA was extracted from cultured amniotic fluid cells obtained by amniocentesis during the fifteenth week of pregnancy and cultured for a further five weeks to provide enough DNA for analysis. Radioactively-labelled α globin complementary DNA synthesised on α globin mRNA was then hybridised to the foetal DNA. The results from this technique are quite clear cut but require the greatest precision in mixing the two DNAs and care in making the measurements.

At the ratios of cDNA to DNA used there should be three α globin minus strands (two from the cold foetal DNA and one from the cDNA) to every two plus strands in normal DNA, and therefore the radioactive probe should be 66% hybridised. If two α globin genes are deleted (α thal I) the ratios would be two minus strands to one plus strand, and only 50% hybridisation found, and if three genes are deleted (Hb H disease) the minus : plus ratio would be 3 : 1 and 33% hybridisation found. If in fact all four α genes are deleted in the foetus (hydrops fetalis) no hybridisation would be expected. Unfortunately the α globin cDNA was only 80% pure, the remaining sequences being β cDNA so even in a case of hydrops fetalis around 20% hybridisation would be found. A successful diagnosis therefore rests on the ability to distinguish between 20% and around 45% hybridisation ($\sim$125 c.p.m.) since only the difference between hydrops fetalis and Hb H is clinically important. In the case reported Kan successfully predicted that the foetus examined had α thalassaemia I. Later, twins were diagnosed and the parents had no hesitation in continuing the pregnancy since at least one foetus was known to be unaffected. In the event healthy twins, one male and one female, were born. At least some of the uncertainty in this type of diagnosis will be removed when cloned, and therefore pure, human globin sequences become available.

An even more serious health problem is posed by the diseases associated with faulty β globin chain production, β thalassaemia and sickle-cell anaemia. Reports from a combined Boston and London study (Alter *et al. New Engl. J. Med.* **295**, 1437; 1976) and from Kan's San Francisco group (*Lancet* **i**, 269; 1977) announce encouraging progress in the prenatal diagnosis of both these diseases. In both cases there is an error of β globin expression rather than a gene deletion; in β thalassaemia no β globin chain is produced and in sickle-cell disease a mutant globin chain(β_S). Therefore analysis can only be carried out on cells which actually produce globin—the foetal blood cells.

The biochemical problem has been elegantly solved. The blood cells are incubated with ^{3}H-leucine and the resultant globin chains analysed on carboxymethylcellulose chromatography columns. In the case of β thalassaemia the β/γ globin ratio is measured and in the case of sickle-cell disease the presence of β_A or β_S is determined. Prenatal diagnosis is possible because even in the first trimester of pregnancy 10% of the β-like chains produced are β rather than the foetal γ globin.

Serious problems in interpretation could arise if the blood sample were contaminated with maternal cells. The Boston–London group overcame this problem by transfusing the mother to reduce her reticulocyte (globin-producing cell) count before foetal blood sampling and the San Francisco group used anti-i serum, an antibody that agglutinates foetal cells. Both groups detected homozygous β thalassaemia and homozygous sickle-cell disease *in utero* and their results were confirmed after abortion.

However, both groups also found foetal blood sampling a hazardous procedure and altogether 6 out of 55 foetuses were lost as a result of attempting to sample foetal blood (three from each centre). The Boston–London group used placental aspiration when there was an anterior placenta and foetoscopy for a posterior placenta. The San Francisco workers used placental aspiration in both cases. The Boston-London workers found foetoscopy less hazardous and since their very first attempts they have had far greater success. The one case in which they wrongly predicted a healthy baby was the result of an insufficient foetal blood sample.

Although the results of the two groups combined are very encouraging it is clear that attempts to take foetal blood during early stages of pregnancy can be very dangerous and the continuing use of these methods for prenatal diagnosis depends on this procedure's becoming much safer. As pointed out in an editorial in the *British Medical Journal* (**531**, 532; 1977) it will also be necessary to simplify the biochemical procedures and the apparatus involved before these techniques can be applied in the parts of the world where these diseases are common. ☐

Polarity time scale extended by 2 Myr

from Peter J. Smith

WITH the possible exception of any very short events remaining undetected, the details of the geomagnetic polarity time scale based on radiometrically-dated subaerial igneous rocks of the past 4.5 Myr have been known for some time. It would now clearly be desirable to extend this well-established scale backwards, partly to increase its usefulness as an aid to stratigraphic correlation and partly to reduce the errors involved in matching it to much longer polarity reversal patterns (for example, from oceanic magnetic anomalies and deep-sea sediment cores) based largely on relative dating. Unfortunately, however, this is far from easy. For one thing, with increasing age it becomes more and more difficult to find rocks which remain unaltered and thus not subject to geological 'errors' such as loss of radiogenic argon. But even where suitable material is available, beyond 4–5 Myr, potassium–argon ages have precision errors comparable to many of the time intervals to be resolved.

One way out of the latter dilemma, as McDougall *et al.* (*Geol. Soc. Amer. Bull.* **88**, 1; 1977) have found, is to concentrate on a long stratigraphically controlled sequence of rocks and rely on mathematical techniques to smooth out data points which individually would not be sufficiently precise to define polarity boundaries. The sequence that McDougall and his colleagues chose comprised more than 400 successive lavas in Borarfjördur, western Iceland, with a total thickness (including interbedded sediments) of more than 3,500 m. The palaeomagnetism was straightforward; most of the lavas gave reliable directions and thus polarities and a reversal pattern. The sucess rate for potassium–argon analysis, on the other hand, was much lower. In fact, only 24 samples were considered suitable for dating on the basis of minimal alteration of primary mineralogical phases and minimal development of secondary minerals.

The selection of rocks for radiometric dating is admittedly still largely subjective. Although fresh well-crystallised lavas are generally suitable and highly altered lavas are obviously useless, there is particular difficulty in deciding whether or not only slightly altered samples should be rejected, especially where (as in Iceland) completely unaltered rocks are so rare that little progress could be made with them alone. In this case, however, there were ways of assessing the overall reliability of the results obtained. For example, the 24 potassium–argon ages determined by McDougall *et al.* were generally consistent with the stratigraphy, suggesting them to be fairly good indicators of the ages of crystallisation of the lavas rather than of the age of any subsequent burial metamorphism. Indeed, they showed no correlation at all with the positions of the rocks with respect to Iceland's well-mapped zeolite zones.

So accepting that their measured ages were "valid estimates, to a first approximation, of the time since the lavas were erupted", McDougall and his coworkers then proceeded to carry out a simple linear regression analysis of determined age against the aggregate thickness of the lava–sediment sequence measured from its base. Notwithstanding the implicit assumption here that the sequence accumulated at a uniform rate throughout, the best-fitting age-thickness curve gave an age of 3.27 Myr for the clearly-recognisable Gauss–Gilbert boundary. This is in good agreement with the well-established age of 3.32 Myr for this boundary, suggesting that both the basic data and the assumptions made in analysing them were valid. Even so, to normalise the data a new regression analysis was carried out using only rocks older than the Gauss–Gilbert transition fixed at 3.32 Myr.

The revised regression line together with the polarity data give an age of 5.34 Myr for the Gilbert–Epoch 5 boundary, 5.83 Myr for the Epoch 5–Epoch 6 boundary and 6.54 Myr for the Epoch 6–Epoch 7 boundary. The Cochiti and Nunivak normal events within the Gilbert reversed epoch appear as a single event lasting from 4.09 to 3.86 Myr ago—a failure of resolution possibly arising from a hiatus in the eruption of lavas at the critical time. However, the two normal events in the lower Gilbert, termed C_1 and C_2 by Opdyke (*Rev. Geophys. Space Phys.* **10**, 213; 1972), appear separately, covering the periods 4.45–4.33 Myr and 4.81–4.60 Myr, respectively. The names 'Sidufjall event' for C_1 and 'Thvera event' for C_2 are now proposed.

As for older epochs, the unnamed reversed event previously recognised within normal Epoch 5 by several groups of workers is now seen to cover the period 5.50–5.37 Myr whereas the unnamed normal event previously seen within reversed Epoch 6 covers the period 6.39–6.27 Myr. But McDougall *et al.* also find two further normal events within Epoch 6—very short ones at 6.43 Myr and 6.12 Myr. Apparently these have not been detected previously either in marine magnetic anomalies or in deep-sea cores.

No doubt some of these ages (which have uncertainties of 0.1–0.2 Myr) will be subject to amendment by subsequent workers; it would be surprising if that were not to be so. In the meantime, however, McDougall and his colleagues have made a major contribution in extending the polarity time scale based on subaerial rocks back about 2 Myr further than previous attempts. Incidentally, the extended scale now covers the Miocene–Pliocene boundary for which McDougall *et al.* propose a revised age estimate of 5.2±0.1 Myr although admitting that there may be data (for example, from New Zealand) inconsistent with this figure. ☐

Earthquake prediction

from E. R. Lapwood

The Fifth US–Japan Seminar on Earthquake Precursors, sponsored by the Japan Society for Promotion of Science and the National Science Foundation, met in Tokyo on 17–19 January 1977. It was organised by Professors Z. Suzuki and C. Kisslinger and the proceedings will be published as a special number of the *Journal of The Physics of the Earth.*

Hopes that monitoring of the ratio of speeds of sound and shear waves in stressed rock would be the key to earthquake prediction have been disappointed, but Japanese and American seismologists believe that successful prediction will be achieved. When, however, will depend on the intensity of effort, on the level of funding and on effective international cooperation.

In both Japan and the US the budget directly provided for earthquake prediction research runs into millions of US dollars. (The 1976 US programme was for $5 million, and the Japanese—much greater—for $8 million not including salaries, Seismologists in both countries are hoping for increased support in 1977.) Especially in Japan this earmarked budget is to be seen against a background of highly efficient routine observations and widespread research in universities. Papers presented to the seminar showed that understanding of earthquake origins and mechanisms is advancing on a wide front; and that that is essential in view of the complexity of the problems and the variety of possible premonitors.

Experimental work on the behaviour of rocks (and other materials) was described by W. Brace (Massachusetts Institute of Technology) and K. Mogi (Tokyo University). Brace emphasised the important differences in behaviour of intact rock and 'gouge' (the crushed material created at the rough interface by sliding on a fault), in particular as regards dilatancy (expansion just before breakdown) and its accompanying effects. At a huge fault with a history of repeated movements in recent time the layer of gouge may be very thick, whereas at a fault with no such character it may be thin; thus the response of the material just before slip on the fault, and premonitory signals, may be very different. Mogi described his experiments on dilatancy of rocks under triaxial stress. Previous experimental work had been mainly with axial symmetry. When the three principal stresses are unequal the response is more complicated and more realistic, so that Mogi was able to describe effects very relevant to earthquake mechanics.

The importance of Japanese records often emerged. For instance W. Thatcher (US Geological Survey) reported that analysis of peat layers in a trench cut across the San Andreas fault enabled movements in the past 1,500 years to be listed, giving an average interval of 170 years between large local movements. But T. Matsuda (Tokyo University), using Japanese historical records, was able to classify all active (that is, Quaternary) faults in Japan according to estimated slip rate and recurrence time, and to set upper and lower bounds on the greatest earthquake to be expected on a given fault at a given time. Again, the recent discovery of anomalous uplift between 1960 and 1974 in Southern California has led US agencies to allocate $2.1 million for its observation and study. In Japan, on the other hand, 20,000 km of levelling has been covered five times since 1884 (except for Hokkaido) and geodesists are already in a position to detect anomalous uplifts in any part of the country. At present the Tokai region (southwest of Tokyo) has been designated as an "area of intensified observation", partly because of increased crustal movement since 1974.

E. R. Engdahl (NOAA) described the results obtained by himself and C. Kisslinger (University of Colorado) from two high-gain high-frequency seismograph networks in the central Aleutians. The high level of seismic activity and the precision with which epicentres within the net, and depths of foci, could be located produced splendid maps and cross sections, by means of which the migration of activity could be followed, and the pattern of foreshocks and aftershocks of a moderate (m_b5) earthquake examined in remarkable detail. Equally impressive were the results achieved at the Observation Centre for Earthquake Prediction at Tohoku University. A. Takagi (Tohoku) showed graphs of the hypocentre (focus) distribution of intermediate-depth micro-earthquakes below the North-East Japan arc. He demonstrated a double-plane structure, sources lying on parallel dipping planes separated by 30–40 km.

S. Suyehiro (Japan Meteorological Agency) described the close coverage of the Japanese islands with seismograph stations, and plans for telemetering and for emplacing ocean-bottom seismographs which in a few years should enable the hypocentres of earthquakes of magnitude $M>3$ to be computed in real time (as the earthquakes happen). Fault–plane solutions, describing the source mechanism, are routinely computed for events of $M>5$. Local seismograph networks, operated by various universities, are able to see the fine structure of hypocentres among foreshocks, aftershocks and seismic swarms.

But neither these agencies nor any other in Japan or the US has been able to identify regularly occurring seismic precursors in the form of anomalous velocity ratios or P delays. Only for compressive stress in hard rock—and not always then—do such precursors appear. Moreover, Japanese seismologists have a good deal of evidence that dilatancy is confined to crustal rocks. T. McEvilly (University of California, Berkeley), in a review of the present state of knowledge of precursors, gave the following rough estimates of thresholds above which a long-term coherent anomaly could be distinguished from noise (Table 1).

He considered that it was not yet possible to give a similar table for expected values of precursors; deformation precursors are well documented, but there is serious difficulty in predicting the time of the main event; other physical and chemical parameters have not yet been shown to give consistent indications; animal behaviour should, if it is significant, lead to measurable physical parameters.

Much interest was aroused by the paper by S. Suyehiro and H. Sekiya (Japan Meteorological Agency) on anomalous seismic activity (not classed as foreshocks) before seismic events, and by the paper by C. Scholz (Columbia University), on a possible deformation front moving across North China at about 110 km yr^{-1} at the time of the earthquake at Hai-cheng (Liao-ning province).

Having given a pessimistic estimate of the possibility of compiling during the next 10 years enough case studies of large earthquakes of different types to make prediction of destructive earthquakes feasible, F. Press (Massachusetts Institute of Technology) appealed for the pooling of resources in instruments and men for a cooperative effort from China, Japan, USA and USSR—the countries which now exert 90% of relevant worldwide research effort.

Z. Suzuki and C. Kisslinger (University of Colorado), joint organisers of the symposium, pointed to the rising public demand for earthquake prediction, and emphasised the need for seismologists to learn to speak intelligibly to ordinary people. H. Ohta (Tokyo University) and E. Haas (University of Colorado) reported surveys of social attitudes and responses; from these it was very clear that the education of the public to understand statements of probability and to respond rationally must precede announcements predicting earthquakes. In fact, it must begin at once in countries at seismic risk. □

Table 1

Differential magnetic field	1γ in 10 km
Electrical resistivity	1% change in 10 km
Electric field	1+% change in 10 km
Atmospheric electric field	? 200%
Radon content in wells	20% in a few months
Water level in wells	Depends on local conditions
Strain	1 in 10^6
Tilt	1 microradian
Uplift	
Levelling	1 cm in 10 km
Gravity	3×10^{-8}g
Differential sea-level	2–5 cm
Travel times of seismic waves	
Relative P delays	
(beyond 40° and between stations within 50 km)	0.1 s
V_p/V_s ratio	
(over periods of months, with good processing)	0.1
Velocity changes from local earthquakes	1%
Controlled sources	
(explosion, air-gun, vibrator)	10^{-4}–10^{-3}

Optical fibres at Williamsburg

from J. Baker

The Second Conference on Optical Fibre Transmission was held at Williamsburg on 22–24 February, 1977.

THE effort in fibre optics communications technology (the transmission of information by light pulses travelling down hair-like fibres of glass) is concentrating on realising on a practical level the inherent advantages of the system—high bandwidth, immunity from electrical interference, small size, and low cost.

Many organisations reported the results of field tests on complete information-carrying networks suited to a variety of applications. N. Shimodaira (Nippon Electric Co.) reported the results of field tests on a high bit rate (400 Mb s^{-1}) optical link, the transmission of such high bit rates being made possible by two factors. First, the gradient of the refractive index in the fibre is carefully built up during fabrication, decreasing smoothly from the centre to a constant value in the "cladding". This results in nearly equal group velocities for the various propagating modes which each pulse of light excites. Second, the modes excited by the pulses of light are restricted to those of low order, thus further reducing the total spread. Ga–Al–As semiconductor laser diodes were used to launch pulses into the fibres, and avalanche photodiodes were used to detect them at the receiving end. At the other end of the spectrum W. H. Hackett (Bell Laboratories, Murray Hill) reported the results of tests on short-haul low bit-rate (16 and 32 Mb s^{-1}) data links incorporating light-emitting diodes to launch the pulses and PIN photodiodes to detect them.

Information transmission by way of optical links has inherent advantages in environments where high electric fields are present. T. Sekizawa (Fujitsu Laboratories Ltd) reported the results of a cooperative venture which has demonstrated this convincingly in field conditions. They found that the performance of their optical fibre links, which were routed through ducts containing power cables, were not measurably degraded by proximity to high voltages.

Several papers were devoted to splicing techniques. The contribution by P. K. Runge (Bell Telephone Laboratories, Holmdel) and W. C. Young (Western Electric) was notable, the connector described being moulded directly to the protective sheath of the optical fibre. The authors quoted losses per connector in the region of 0.4 dB. However it was clear that more work is necessary before a viable splicing system becomes available for general field use.

In the field of fibre fabrication a great deal of effort has been devoted to producing consistently very strong fibres. Both C. Kao (ITT Electro-Optical Products Division) and C. R. Kurkjian (Bell Laboratories, Murray Hill) quoted breaking strengths in excess of 500 k.p.s.i. for 125 μm diameter fibre by ensuring that surface defects and contamination of the fibres during manufacture were kept to a minimum. Fatigue strengths of fibres under applied stress were also reported which indicated that potential service lives greater than 20 years can be expected for fibre now being produced.

The overall impression gained was that optical communications systems are now a viable proposition for capacity data links. Concerning the future for long haul telecommunications, the question is now how soon?

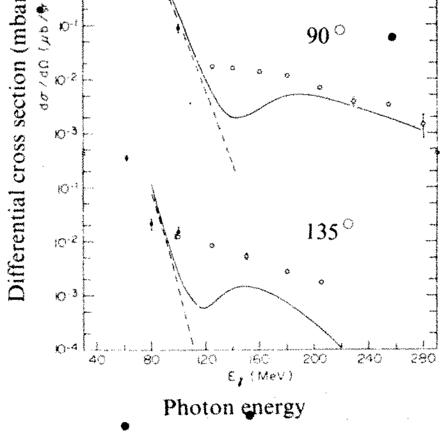
Short range nuclear forces

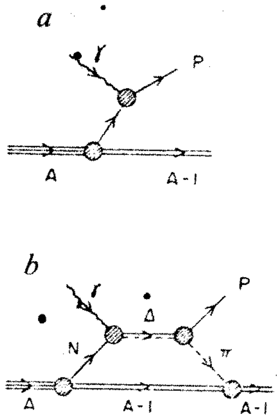
from P. E. Hodgson

EXPERIMENTS on the photo–proton reaction on oxygen from 100 to 300 MeV by a joint MIT–Glasgow group have recently provided evidence that in this energy range the reaction proceeds through the Δ (1232) nucleon isobar as an intermediate state, and it is likely that this process is increasingly important at high energies (*Phys. Rev. Lett.* **38**, 8; 1977).

The experiment was carried out by bombarding a beryllium target with a bremmstrahlung beam and measuring the spectrum of the emitted protons. The differential cross sections for the photo–proton reactions on oxygen that leave the residual nucleus in its ground state are shown for several angles as a function of photon energy in Fig. 1.

It is simplest to suppose that the reaction proceeds by a single-step process in which the incident photon interacts with a single proton in the target nucleus and knocks it out. This is indicated diagrammatically in Fig. 2*a*, and gives the dashed curves in Fig. 1. It is clear that this theory, allowing for uncertainties in the calculations, is in qualitative accord with the data at low energies, but quite fails at higher energies. The calculations are rather rough, since harmonic oscillator wave functions were used, and the distortion of the wave function of the outgoing proton was neglected, but this does not affect the general conclusion.





The experimental cross sections at higher energies are much higher than those given by the one-step process. Such cross sections can be attributed phenomenologically to short-range correlations due to the repulsive core of the nucleon–nucleon interaction or a microscopic model can be made in terms of a two-step process. One such process, involving the Δ (1232) nucleon isobar excited in an intermediate state, is indicated in Fig. 2*b*. Calculation with this process gives the full curves in the figure, when added to the results of the calculations of the one-step process already considered. Although there are differences in detail due to the approximations made in the calculation, it is clear that the overall trends are qualitatively given. This provides evidence that the Δ-process can make a major contribution to the photo–proton cross-section in the 100–300 MeV region, and thus gives further insight into the structure of the short-range nuclear forces. ☐

review article

Some recent developments in remote sensing

P. Schagen*

In recent years electronic instruments have been developed which increase very considerably our ability to view the nocturnl scene at otherwise critically low incident light levels, by using the available reflected radiation more efficiently with the aid of image intensifiers. Still other instruments employ sensors which are sensitive in the infrared and convert the natural thermal radiation of any object in the scene into visible pictures. In this article recent technological developments in image intensification and thermal image conversion are briefly discussed.

REMOTE sensing depends on a large variety of techniques and finds application in a wide range of human interests. The techniques used may be 'passive' methods of obtaining information about a particular parameter of the environment, for example its local variations in emission or reflection of natural electromagnetic radiation. They may be 'active', using probing beams of light (as in laser radar systems and range finders) or irradiating the scene with X rays or ultrasound to obtain pictures for medical diagnosis or non-destructive testing.

It is impossible in a brief article to present a comprehensive survey of the field as a whole. Instead, the discussion has been restricted to some recent developments in two methods of passive sensing of the environment, using image intensification and thermal imaging. Both are of particular importance at very low levels of incident illumination.

Perception at very low light levels

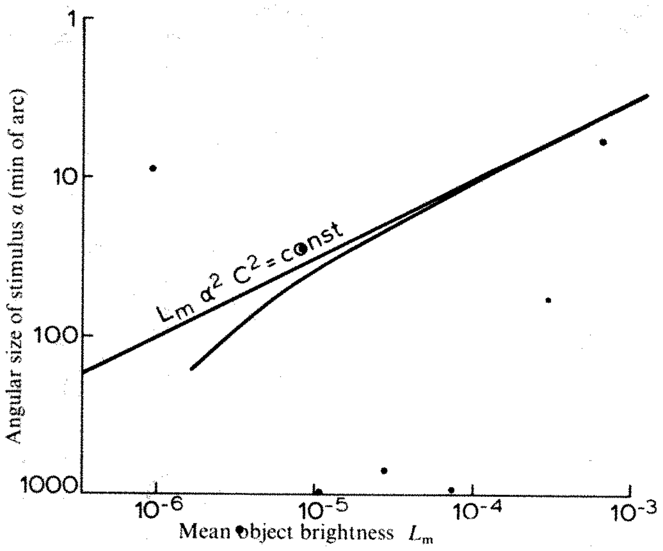
In daytime the visual acuity of the eye is limited only by the retinal cone density and the optical aberrations of the eye lens[1,2], because the level of photon flux is far greater than the level of its statistical fluctuation. On the other hand, at night when incident light is reduced to starlight, airglow and occasionally moonlight, the numbers of photons captured by the eye are so small that their statistical fluctuations become the limiting factor. The eye will only perceive an object detail in the scene if it can detect the difference in illumination of two corresponding adjacent elementary areas on the retina. Each of these areas registers a number of photons, on average, during the integration time of the retina. The difference between these average numbers constitutes the photon 'signal', with an associated photon 'noise', caused by the statistical fluctuations in the numbers during successive integration periods. If the actual numbers of detected photons become so small that the photon-signal is indistinguishable from the photon-noise, then the eye is not able to sense the object detail.

As light level decreases and photon-noise becomes an important factor, the eye tries to compensate for the reduction in the density of photons received in a number of well-known ways. First, the pupil dilates to let the eye capture more photons from the scene—the pupil diameter is 0.2 cm at a brightness of 10^4 cd m^{-2}, but rises to, and levels off at a diameter near 0.8 cm when the brightness is down to 10^{-4} cd m^{-2}. (10^4 cd m^{-2} is roughly the brightness of white paper on a bright summer's day; 10^{-4} cd m^{-2} is roughly the brightness of a cloudy moonless sky at night.)

Second, dark-adaptation takes place: the cones, the sensor elements of the retina which are active in daylight and are responsible for colour vision, cease functioning at a scene brightness below about $10^{-\text{[illegible]}}$ cd m^{-2}, and the rods, which are overloaded in daylight and which are not colour-sensitive, slowly recover and take over. An important aspect of this process seems to be the ability of the neurones associated with the rods to integrate the light signals produced by the rods over larger areas of the retina as the illumination level falls. The minimum signal-to-noise ratio required for the detection of a picture detail can thus be maintained during a reduction in scene brightness by several orders of magnitude for correspondingly larger areas on the retina, leading to a gradual decrease in resolving power.

The third effect on the eye of a reduction in scene brightness is that the retina integrates the signal over longer time intervals,

Fig. 1 Typical acuity curve of the eye for a bright stimulus on a black background, together with a straight line expressing the relationship of equation (1).



---

*Applied Physics Division, Mullard Research Laboratories, Redhill, Surrey, UK.

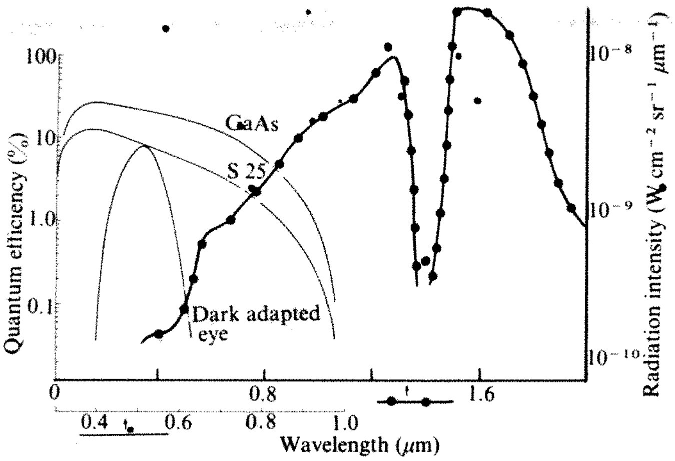


Fig. 2 Typical spectral response characteristic of a dark adapted eye in comparison with a multialkali photocathode of the S25 type, and with a GaAs photocathode[10,11]. The quantum efficiency curve for the eye is based on the relative energy response curve of ref. 3, p. 73, while assuming a maximum quantum efficiency of 8% at 0.507 µm, as calculated from equation (1) and Blackwell's measurements. Added (●–●–●) is a typical spectral distribution of night sky radiation.

up to about 0.2 s, thus again achieving the minimum signal-to-noise ratio required for perception from correspondingly dimmer details, but now at the expense of perceiving movement. A critical flicker frequency can be defined which is linearly related to the logarithm of the stimulus brightness over a wide range of brightness values. This effect is still noticeable at much higher illumination levels, such as that of the fluorescent screen of a television receiver, where an irritating 50-cycle flicker can become apparent if the screen brightness is set too high.

The performance of the eye, like that of any image-forming instrument, can be described with the aid of acuity curves, relating the resolving power (and thus the detection range) to brightness and contrast on a logarithmic scale[3,4]. If photon noise is the fundamental limitation at the lowest light levels, then these acuity curves can be represented there by relations of the type[5]

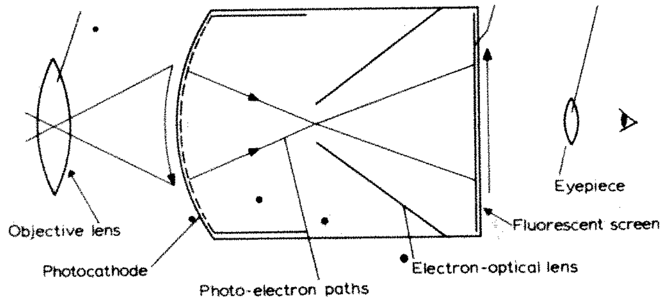
$$L_m\alpha^2C^2\tau = \text{constant} \qquad (1)$$

where L_m is the mean brightness ($L_m = \frac{1}{2}(L_{high} + L_{low})$ in cd m^{-2}) of two adjacent object elements forming the detail with an optical contrast C, defined as $C = (L_{high} - L_{low})/(L_{high} + L_{low})$, α, the acuity, is the minimum angle (minutes of arc) subtended by each of the two object elements at which their difference in brightness can still be detected, and τ is the integration time.

The constant in the right-hand side of equation (1) can be written as

$$\frac{7.5 \times 10^{10}(S/N)^2_{min}}{D_{eff}{}^2\,\theta P}$$

Fig. 3 Schematic diagram of an image intensifier tube.



where D_{eff} is the effective diameter (cm) of the objective lens of the instrument, θ the quantum efficiency of the sensor and P the number of photons per second equivalent to 1 lm of the radiation employed; both θ and P depend on the spectral distribution of the light (1 cd m^{-2} = π lm m^{-2} on a white surface). $(S/N)_{min}$ is the minimum signal-to-noise ratio required for detection of the object detail. Its value depends on the kind of object detail which the detector must resolve. For some test objects the value of $(S/N)_{min}$ can sometimes be determined mathematically with the aid of probability theory[6], by considering the number of alternative choices available and the reliability required in the decision. Blackwell[7], for instance, has measured acuity curves of the eye by asking observers to look at a circular disk, flashed on to the screen for a short period in any one of eight positions, and requiring a reliability of 50% in the answer. For this situation it can be shown that $(S/N)_{min} \sim 1.5$.

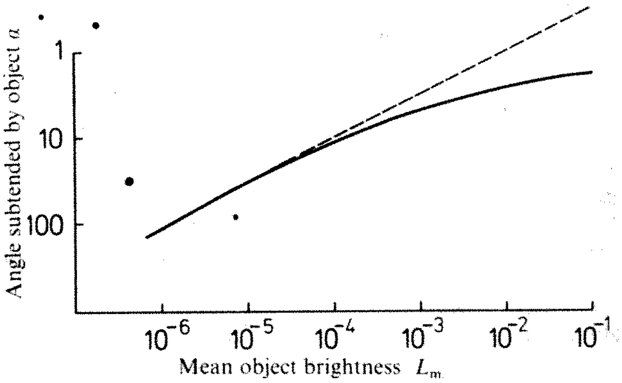


Fig. 4 Schematic acuity curve (arbitrary units) of an image detector. The dashed line is the equation $L_m\alpha^2C^2\tau$ = const. At low brightnesses the detector is photon-noise limited; at high brightness the optics limits resolution.

In Fig. 1, a typical acuity curve of the eye is plotted from Blackwell's data[7] for a high-contrast (C = 1) bright stimulus on a dark background. The curve closely approximates the straight line of the photon-noise limited condition, indicated by equation (1), over several orders of magnitude of the light level L_m, with a value of $L_m\alpha^2$ equal to approximately 10^{-2}. If the diameter of the dilated pupil is taken to be 0.76 cm, and a binocular summation factor of 1.26 is assumed[8] to take into account the use of both eyes in Blackwell's experiments, then D_{eff} can be taken to be 0.85 cm. So for τ = 0.2 s and $(S/N)_{min}$ = 1.5, Blackwell's data indicate a quantum efficiency of the dark-adapted eye of just below 1% for 'white' light with 1 lm equivalent to about 1.3 × 10^{16} photons s^{-1}.

At 0.507 µm, where the dark-adapted eyes of young people have their maximum, 1 watt is equivalent to 1766 lm (ref. 9). This leads to P = 1.45 × 10^{15} photons s^{-1}, indicating a maximum quantum efficiency of the dark adapted eye at 0.507 µm of about 8%, according to equation (1). To improve further on the capabilities at low-light levels we may turn to image intensifiers.

Image intensifiers

Instruments of this kind collect more photons from the scene with the aid of a larger lens diameter (up to tens of centimetres) than that of the dark-adapted eye. They use these photons more efficiently, by means of sensors with a larger quantum efficiency than that of the retinal receptors and a spectral sensitivity extending further into the infrared region, as shown in Fig. 2. By so doing they take advantage of the rapid rise in intensity of night-sky radiation (also shown in Fig. 2).

The sensors are image intensifier tubes, first suggested in a patent in 1928 (ref. 12) and illustrated in Fig. 3. The output image can be several thousand times as bright as the image projected on the cathode. An important condition is that the brightness gain is sufficiently high to ensure that an electron created by a photon at the photocathode gives rise to so many photons on the fluorescent output screen of the tube that it will be detected by an observer even if not fully dark adapted.

The performance of the instrument can again be described with the aid of acuity curves, similar to that of Fig. 4, approaching the photon-noise limitation at the lowest light levels and limited by its optical imperfections, as measured by its optical modulation transfer function[13, 14], for the smaller picture details. The main improvements over the unaided eye at low light levels are due to the much larger product $D_{\rm eff}^2\theta P$ in equation (1).

Two types of image intensifier tube can be considered for modern night viewing equipments, both providing sufficiently high brightness gain to satisfy the condition formulated above. The first, now well established in production instruments, uses so-called cascade tubes[15], illustrated in Fig. 5. Single-stage image intensifier tube modules are stacked in cascade, using fibre-optic coupling between the output screen of one module and the photocathode of the next. Each fibre-optic window contains millions of glass fibres with diameters of less than 10 μm. Up to three modules are encapsulated together, complete with a miniaturised wrap-around high-voltage supply unit.

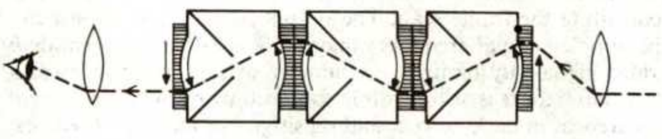

Fig. 5 Principle of operation of a three-stage cascade tube.

High brightness gains can also be achieved by channel electron multiplication[16–19], illustrated in Fig. 6. A hollow tube or channel is shown, usually consisting of a glass with suitable electrical conductivity. When a potential is applied between two end electrodes an accelerating electric field is established down the length of the channel. An electron entering the cathode end of the channel strikes the wall and releases a few secondary electrons. These will be drawn further into the channel under the influence of the accelerating field, and strike the opposite wall at a higher potential, thus releasing further secondaries. The process is repeated several times, giving rise to a large bunch of electrons like an avalanche emerging at the exit for one initial electron.

Since the electron gain depends critically on the length-to-diameter ratio of such a channel and the voltage applied, it is possible to make the individual channels very small and stack them together in a mosaic or channel-plate of a few centimetres diameter and less than a millimetre thick. When such a plate, containing nearly a million channels of 10–15 μm diameter, is placed in front of the fluorescent screen of a single-stage image intensifier tube, brightness gains in excess of 100,000 can easily be obtained. Image tubes of this kind can achieve a better picture quality than cascaded stacks, and lead to smaller and lighter instruments. In addition, channel multiplication has the advantage of local saturation of highlights, owing to the limited supply of secondary electrons available from the wall of each channel. This characteristic substantially reduces the disturbing effect of bright light-sources in the field of view without affecting the gain in darker parts of the scene. The insertion of the channel plate in the paths of the photo-electrons does, however, lead to a loss of some primary electrons which hit the solid web of the plate surrounding each channel, thus missing the entrance to one of the channels.

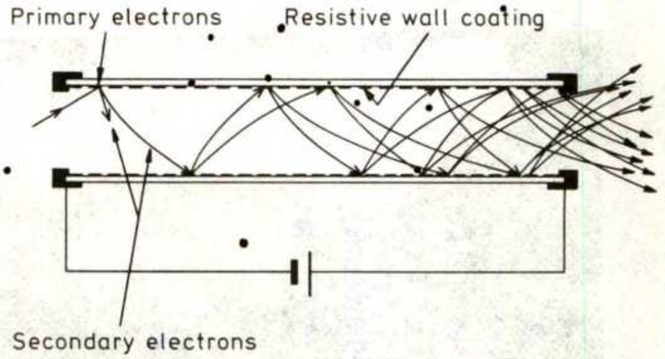

Fig. 6 Illustration of the process of channel electron multiplication.

Channel electron multiplier tubes can be used in small light-weight goggles, as shown in Fig. 7, and are also suitable for other applications. They can, for example, easily be combined with a television camera tube of the vidicon type to provide a comparatively simple approach to low-light-level television[20]. In this case the high-light suppression characteristic of the channel tube, and the ease of providing automatic brightness control are important assets. Figure 8 shows photographs taken from the output screen of a channel tube for two different levels of illumination and brightness gain. The picture taken in starlight shows clearly the scintillations corresponding to individual photons.

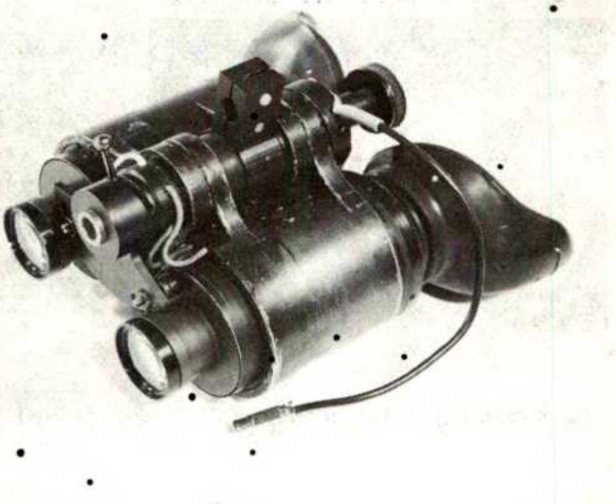
Thermal imaging

An alternative approach to remote sensing of the environment is to use the natural thermal radiation from the scene. The spectral energy distribution of this black-body radiation is given by Planck's law.

For a black body at room temperature this energy peaks at a wavelength of about 10 μm, with very little energy below 2 μm. Figure 2 showed that the photocathodes used in image intensifier tube have practically no sensitivity at wavelengths above 1 μm. It is therefore not possible to convert thermal images to visible wavelengths with the aid of conventional image intensifier tubes, and it is necessary to replace photoemitters as the primary sensors by detectors of which the spectral sensitivity does extend well beyond 1 μm. These can be photoconductive or photovoltaic cells, where absorbed individual infrared photons can create corresponding charge carriers in the semiconductor material. Alternatively a bolometric effect can be used where the absorbed radiation gives rise to local changes in temperature of the detector material, of which a physical parameter with a high temperature coefficient is measured for every picture element.

A black body of 290 K, that is with a temperature close to

Fig. 7 Photograph of a pair of light-weight goggles, containing channel image intensifier tubes.



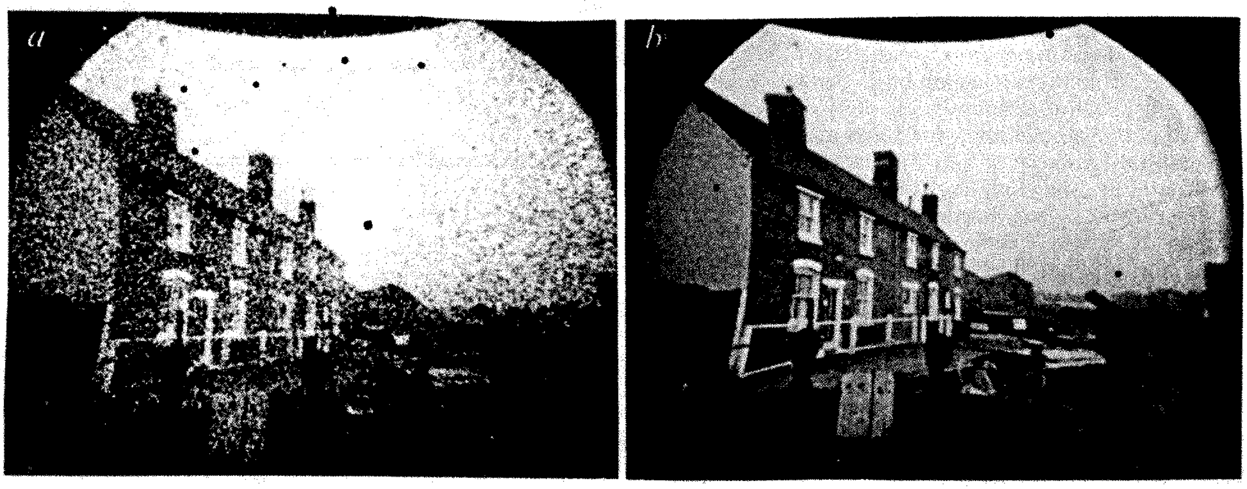


Fig. 8 Photographs taken from the output screen of a channel image intensifier tube, exposure time 1/8 s. *a*, Starlight illumination, brightness gain approximately 100,000. *b*, Full moonlight, brightness gain less than 10,000.

that of most objects in the natural scene, emits approximately 10^{18} photons s^{-1} cm^{-2} in the wavelength region up to 20 μm. (Compare this with the 10^{17} photons s^{-1} cm^{-2} in the visible region incident from the sky in sunlight or 5×10^{9} photons s^{-1} cm^{-2} in moonlight.) The actual numbers of photons available for thermal imaging are thus far larger than those reflected from an object illuminated by the night sky, and even exceed those reflected by sunlit objects by a substantial factor.

In reflected light the image contrast can be very high, exceeding 0.99. But, because the apparent black-body temperature of different natural objects in the nocturnal scene normally differs by not more than about 1 °C, the contrast in the thermal image will be very much lower, and depends on the wavelength region used. For example, if all the photons up to 3 μm wavelength were used, then the contrast for 1 °C temperature difference would be 0.06. This reduces to 0.03 for wavelengths up to 6 μm, to 0.02 up to 10 μm and 0.015 for wavelengths up to 16 μm.

With such a low contrast, a target composed of a large number of small sensors, arranged in a two-dimensional array, can easily give rise to a serious spatial noise, comparable with a 'dirty window' effect, because of small variations in sensitivity and dark-current of the individual sensors, giving rise to variations in output current comparable to those caused by the thermal signal. The simplest way of avoiding this problem is to use one single sensor cell and scan the image mechanically across it. Spatial variations are thus completely eliminated, but the approach is very uneconomical in its use of the incoming radiation and requires high-speed mechanical scanning.

A compromise solution is to use a linear array of sensor cells and scan the thermal image of the scene mechanically across this array in one or more sweeps by wobbling the optics, to constitute the frame scan. The output of each cell in turn can be sampled at high frequency in order to create the conventional video signal. By limiting the number of sensors to at most a few hundred, it is still possible to select arrays with only small differences in dark current and sensitivity of individual sensors, or even to correct for these.

The performance of such thermal imaging systems, using arrays of n sensors, is again noise limited according to a relationship which can readily be derived from the one calculated by Chiari and Jervis[21]

$$\Delta T_N \alpha = \text{constant} \qquad (2)$$

where ΔT_N is the noise equivalent temperature difference, that is, the difference in black-body temperature between two object elements in the scene for which the corresponding signal component of the detector output current just equals the combined noise current of all the cells and α is the angular resolution (in radians). The constant describes system characteristics and can be written as $4(f/D^2)(p/n)^{\frac{1}{2}}(1/M^*)$ where D is once again the diameter of the objective lens (in cm); f its focal length; p the number of cells scanned per second (equivalent to the bandwidth of the video signal) and M^* the figure of merit of the detector material, indicating the sensitivity of the detector to differences of temperature in the scene. The figure of merit also takes into account a given atmospheric absorption of the infrared radiation.

Table 1 gives typical values of M^* for a number of detector

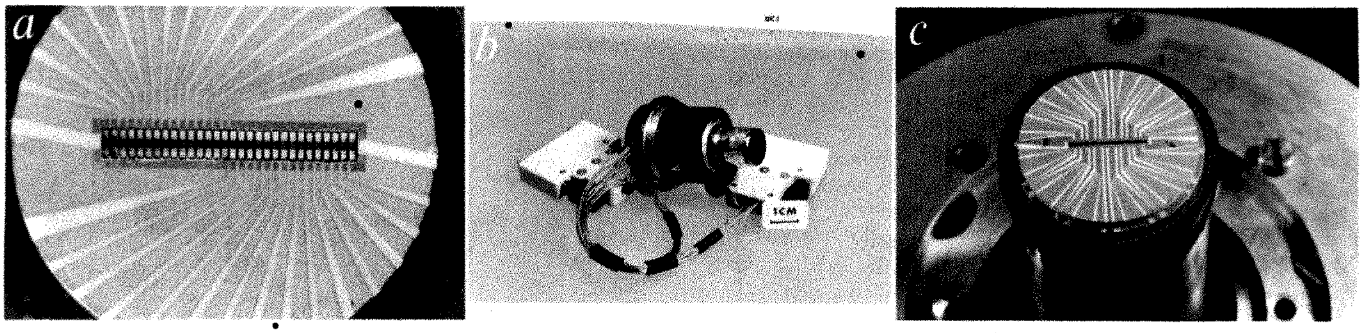

Fig. 9 Photographs of linear arrays of CMT cells, courtesy F. D. Morten of Mullard Limited, Southampton. *a*, 30-element array of CMT cells, 115 × 125 μm. *b*, As (*a*) mounted. (*c*) 192-element array of CMT cells, 50 × 50 μm.

systems produced in arrays, allowing for typical transmission at a range of 2 km (ref. 22). For the smaller values of α the just perceptible temperature differences in the scene, given by equation (2), will again be restricted by the degradation in resolution caused by the optical components. Equation (2) does, however, indicate that high-performance thermal imaging is feasible with linear arrays of sensor cells. Recognisable images of a natural scene can be formed when temperature differences do not exceed about 1 °C. It should, for example, be possible to obtain television-type pictures with a temperature resolution of 0.1 °C, together with an angular resolution of 0.2 mrad and a total viewing angle of about 7°, for an objective lens with $f = 30$ cm and $D = 20$ cm, a picture of 400×600 picture elements and 25 frames per second, if a value for $M^*n^{\frac{1}{2}}$ of about 3.67×10^7 is achieved. This should be obtainable with an array of approximately 150 photoconductive cadmium mercury telluride (CMT) cells ($M^* \sim 3 \times 10^6$) at 77 K, provided that the optics are not yet limiting the resolution.

Sensors of this kind can now be manufactured in arrays of up to several hundred individual elements with sizes typically down to about 50 µm. Arrays of 30 and 192 CMT sensor elements, with leads connecting bonding pads at the edge of the carrier directly to the elements, are illustrated in Figure 9.

The photographs of Figure 10, courtesy of Mr. W. D. Lawson of RSRE, Great Malvern, illustrate the type of thermal picture obtainable in the 8–13-µm band with 30-element arrays of CMT, cooled to 77 K. The angular resolution of the equipment used was 0.25 mrad, the field of view 10° × 4° and the frame rate 25 pictures per second. Arrays and individual cells for thermal imaging systems with lower temperature and angular resolution are also commercially available. These include CMT cells for operation at intermediate temperatures of 193 K to 233 K. These temperatures can be achieved with the aid of comparatively small and compact thermo-electric coolers[23].

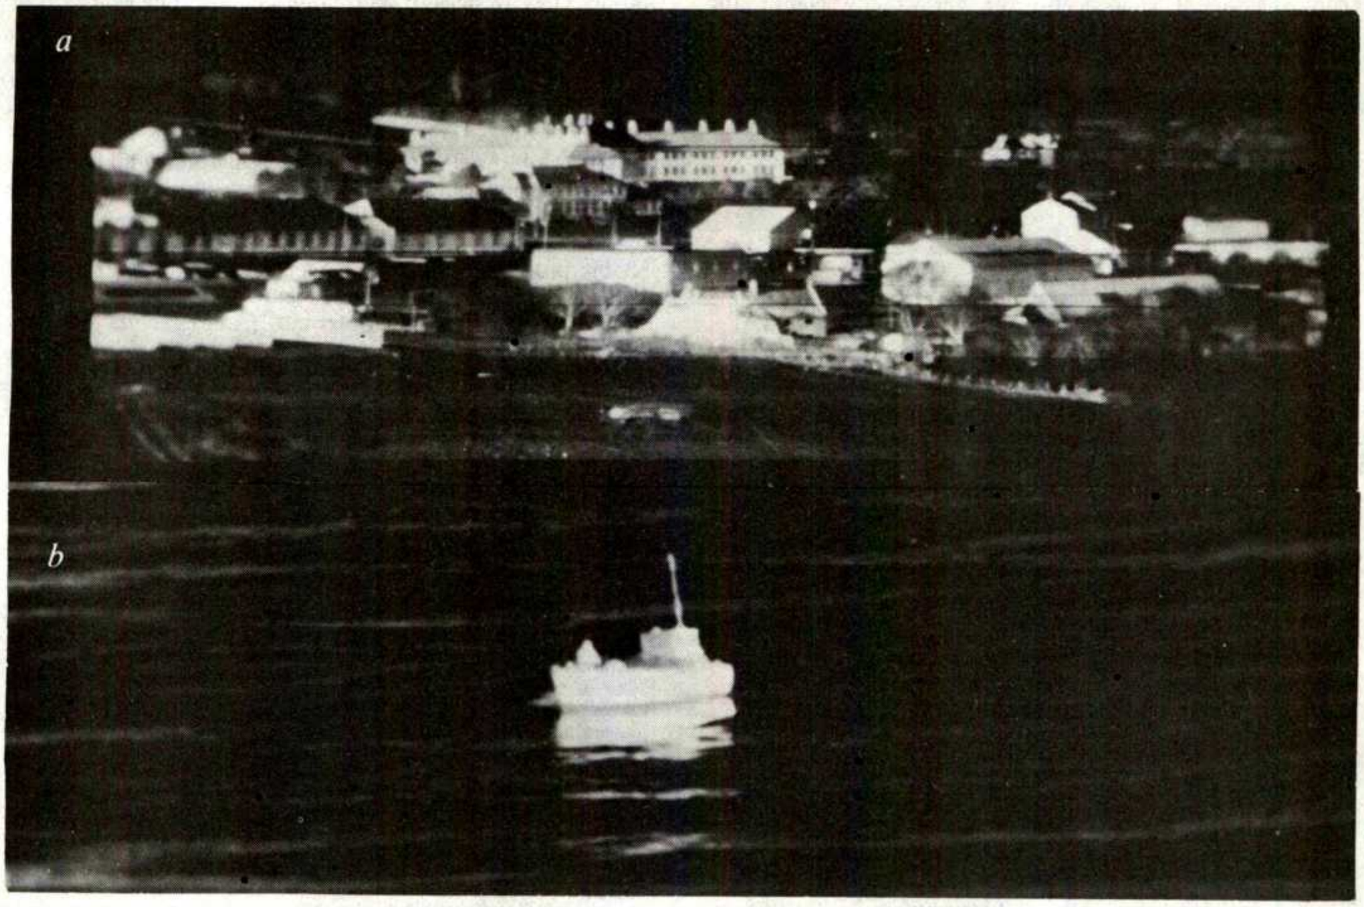

Fig. 10 Thermal pictures obtained with 30-element CMT arrays. *a*, A housing estate in daytime; *b*, A small fishing boat at night.

Table 1 Typical values of M^* for detector systems produced in arrays

Detector systems available	Element temperature	Frequency (Hz)	M^* (cm^{-1}, $\mathrm{Hz}^{\frac{1}{2}}$, K^{-1})
CMT (30 elements)	77 K	5000	4×10^6
CMT (192 elements)	77 K	5000	3×10^6
TGS (128 elements)	295 K	800	10^4
TGS (128 elements)	295 K	125	2×10^4
TGS single element	295 K	800	2×10^4
CMT 3–5 µm band	233 K	5000	10^5
CMT 8–13 µm band	233 K	5000	3×10^4

CMT, cadmium mercury telluride. TGS, triglycine sulphate. M^* is for a 2-km atmospheric transmission path.

A somewhat modified approach to thermal imaging with linear sensor arrays is particularly suitable for airborne photography. In this case an image of the terrain is swept across the sensor or sensors to trace the lines of the picture, whereas the movement of the aircraft provides the much slower continuous scanning motion in the other direction. By recording the video information on a film with continuous uniform movement, a picture of a strip of terrain is gradually built up with high temperature and spatial resolution[24].

An interesting alternative to cooled arrays of photocells is to translate the thermal image into a pattern of electrical charges on a two-dimensional target, and to read these out with the aid of a scanning electron beam, as in a television pick-up tube of the vidicon type, illustrated in Figure 11. Wherever the photoconductive material, which can for example be PbTe (ref. 25) receives infrared radiation, charge can leak to the surface from the positive semi-transparent electrode underneath. The electron beam removes this charge during the next scan, thus creating a signal-current proportional to the local level of illumination.

Instead of using a photoconductive material, it is also possible to make use of the pyroelectric effect[26] exhibited by some materials, such as for instance triglycine sulphate (TGS) or one of its derivatives. Thin slices of such a material acquire electrical charges on the surfaces, whenever the temperature of the material changes. This effect has led to the development of the pyroelectric vidicon[27,28]. Such a tube can translate thermal images of the natural scene into useful video signals with temperature resolutions already down to about 0.2 °C for a 100-line picture.

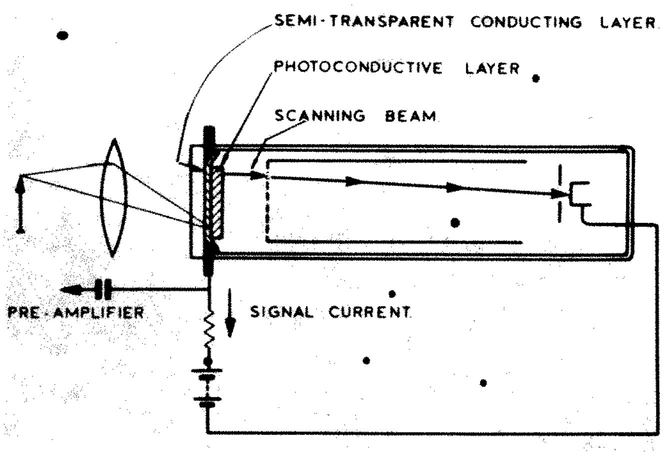

Fig. 11 Schematic diagram of a vidicon.

Further improvements of this approach are still envisaged, both in terms of target design[29,30], and more suitable pyroelectric materials[31,32], which might eventually make it competitive with some of the smaller linear arrays of cooled CMT sensors, but with the advantages of more simplicity, operation at room temperature and not requiring high-speed mechanical scanning.

Whereas image intensification as a means for improved night viewing is now quite close to its theoretical photon-noise limited optimum performance, considerable further improvements in thermal imaging techniques can still be foreseen. These can be expected to result partly from further advances in detector fabrication technology, such as monolithic sensor arrays prepared on chips of single crystal material[33], or even two-dimensional arrays with integral charge-coupled read-out[34–38].

Second, recent advances in signal processing, first developed for improving pictures obtained in the American space programme, can also make a major contribution to increasing the picture quality in thermal imaging, by means of processes like edge enhancement, deblurring, contrast manipulation and extracting small picture signals from noise[39].

Remote sensing methods of this kind, using thermal imaging, are likely to provide a night vision capability to military and security forces[40–43] at longer ranges than can be realised with image intensifiers, partly also because objects of special interest in the scene, like vehicles with their engines running and human bodies, are usually a few tens of degrees hotter than their natural surroundings.

Other applications of thermal imaging

Thermal imaging has so far received its main stimulus as an alternative night viewing aid to image intensifiers for military applications. The thermal pictures received from the scene do, however, provide different information to that normally obtained with reflected visible light, and are therefore also beginning to prove their usefulness in a wide variety of other applications[44–47]. These include geological surveys to map water resources, indicate potential oil and mineral deposits, as well as agricultural inspections to monitor crop development and detect early signs of crop failure due to fungus growth or other diseases.

Other applications are in the fields of medicine[48–50] (thermography), where it may also sometimes be useful to add isothermal contours to the picture[51,52], meteorology, urban planning, energy conservation by optimising the thermal insulation of dwellings, monitoring environmental chemical and thermal pollution, oceanography, astronomy, etc. In some cases the thermal band is divided into a number of separate channels to provide multispectral data[53,54], which can be suitably processed and used to reproduce multicolour pictures in the visible spectrum, thus facilitating even further the identification of particular terrain features with uniquely different spectral characteristics.

The observability of possible atmospheric removal processes for chlorfluorocarbons 11 and 12

Robert J. Gelinas, David K. Hall & Robert G. Nelson

Science Applications, Inc., 80 Mission Drive, Pleasanton, California 94566 U.S.A.

The existence of tropospheric sinks for CFCs 11 and 12 would have a large impact on projected stratospheric ozone effects. The existence of such sinks, distinct from no sinks, cannot at present be discerned from atmospheric measurements. As presently analysed, tens of years may pass before such a distinction would be possible. This article scrutinises transient mechanisms that could contribute to accomplishing this critical distinction in 10 yr or less.

THE issue of possible stratospheric ozone destruction by halocarbons, and specifically chlorfluorocarbons 11 and 12 (CFCs 11 and 12), depends sensitively upon the presence or absence of tropospheric sinks, as indicated by several theoretical studies[1-7] using steady-state and transient one-dimensional (1-D) parameterised transport calculations. These studies focus on: (1) atmospheric CFC mixing ratios for assumed continuing CFC production; (2) Stratospheric ozone depletion for assumed continuing and halted CFC production.

Notably absent, and the subject of this article, is a direct examination of the information content in transient atmospheric CFC ratios following an assumed abrupt reduction of one or more CFCs.

In analysing relatively weak CFC loss mechanisms, weighed against their production and atmospheric transport processes, the present status of the problem is as follows: photodissociation losses of CFCs 11 and 12 above 30 km are generally established[5]; consensus has not been reached on the existence, or non-existence, of other significant loss mechanisms for CFCs 11 and 12[8-10]; observational data[10,11] are sparse, variable and uncertain[9,11]; 1-D theoretical results are uncertain and globally unresolved [8-10,13,14]; CFC production and release data have been extensively compiled and updated[9,12]; and observational CFC mixing ratio data, sparse at present, are growing with increasing efforts towards absolute calibration and accounting of local background effects[9-11].

Estimates have been made of the potential reductions[8-10] of asymptotic CFC mixing ratios that could occur from other atmospheric loss processes acting in addition to CFC photodissociation. Many decades must pass, however, before asymptotic conditions will occur—even if significant tropospheric removal processes do exist.

This article suggests previously unnoted transient mechanisms and trend analysis that, with appropriate development, could contribute to a resolution of this critical issue of tropospheric losses in 10 yr or less.

Calculation procedure

The purpose of our analysis is to assess the physical observability of tentative tropospheric CFC loss processes, without a detailed consideration of complex chemical mechanisms. Our investigative examples employ a conventional 1-D time-dependent representation of the Earth's atmosphere from 0 to 55 km with arbitrary CFC production and loss processes. Atmospheric transport is represented by the computational artefact of vertical eddy diffusion. The descriptive equations for globally averaged concentrations, $C_i(z,t)$ cm^{-3}, are given by

$$\partial C_i/\partial t = \partial/\partial z\{K(z)\rho[\partial(C_i/\rho)/\partial z]\}+P_i-L_i$$
$$i = \text{CFCs 11 and 12} \qquad (1)$$

The vertical eddy diffusion coefficients are denoted by $K(z)$ and, for illustrative purposes, are assigned the values used by

Fig. 1 Relative tropospheric volume mixing ratios for CF_2Cl_2 (CFC 12) ——●——, no sink; — —○— —, 10-yr tropospheric sink. *a*, Source constant after 1974; *b*, source = 0 after 1974.

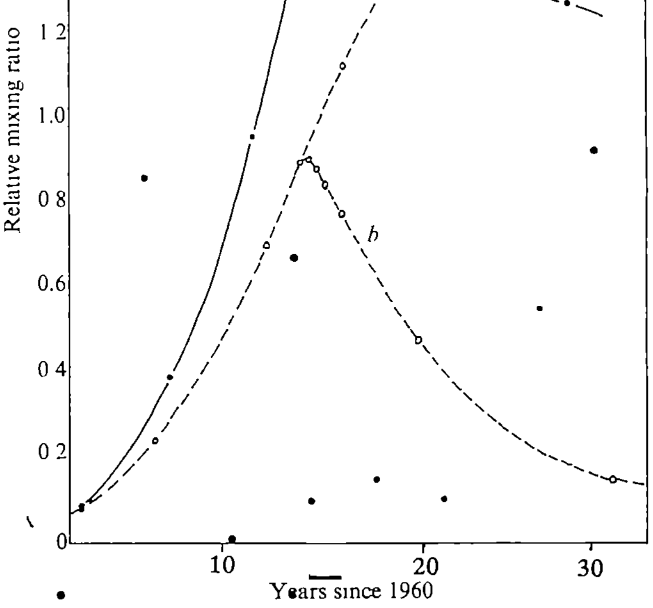

Table 1 CFC mixing ratio trends for the 15–20-yr interval

CFC	Lifetime of assumed tropospheric sink (yr)	Trends for source constant after 1974	Trend ratio (10 yr)/(∞)	Trends for source = 0 after 1974	Trend ratio (10 yr)/(∞)
$CFCl_3$	∞	0.1	~½	−0.02	~2
	10	0.06		−0.04	
CF_2Cl_2	∞	0.2	~½	−0.01	6–7
	10	0.08		−0.07	

Chang[13]. Comparative results with other sets of $K(z)$ appear in refs 9, 15. Natural and anthropogenic CFC production[9] and loss terms are denoted by P_i and L_i, respectively. The atmospheric number density, ρ, is taken from the US Standard Atmosphere[16], and atmospheric mixing ratios are

$$\mu_i(z,t) = C_i(z,t)/\rho(z,t), \quad i = \text{CFCs 11 and 12} \qquad (2)$$

Loss rates are expressed as

$$L_i = J_i\, C_i + (1/\tau_i)\, C_i, \quad i = \text{CFCs 11 and 12} \qquad (3)$$

The photodissociation rates, J_i, are taken from Rowland and Molina[5]. The following additional CFC loss processes will be examined: (1) 10-yr tropospheric sink (τ_i = 10 yr for 0–15 km); (2) 40-yr tropospheric sink (τ_i = 40 yr for 0–15 km); (3) 10-yr stratospheric aerosol sink (τ_i = 10 yr for 15–20 km).

Our calculational procedure was first applied to parameterised transport models with arbitrary sources and sinks by MacCracken and Gelinas[17–19], and extended to include complex photochemical mechanisms by Chang *et al.*[20] This method of casting reactive transport equations into ordinary rate equations for fully implicit, simultaneous integration in space and time is extensively documented, with supportive motivations and assumptions[17–13]. Vertical mesh spacings of 1 km were used, and time-dependent release rates[9] were converted to corresponding globally averaged, time-varying source rates in the 0–1 km zone. Upper boundary conditions of both zero net flux and zero re-entrant flux at 55 km yield the stated results.

Results

Cases (1)–(3) focus directly on circumstances where tropospheric CFC removal processes would be most immediately observable, that is, with inconsequential CFC production, relative to losses. Either abrupt source reductions or total curtailment of CFC 11 and/or 12 can be studied. Total source curtailments are used in our examples because the information content of governing mechanisms is most readily apparent in that limit.

Our primary results are developed from Fig. 1, which presents the relative mixing ratios of infinite against 10-yr, tropospheric lifetimes for CFC 12 with: source rates continuing constant at 1974 levels, subsequent to 1974; or production assumed halted subsequent to 1974. Also calculated, but not plotted, are CFC 11 results which have the same qualitative structure as CFC 12 results. Quantitative differences are noted in Table 1. Also, results for a 40-yr tropospheric sink and a 10-yr stratospheric aerosol sink were calculated, and lie between the 10-yr and infinite lifetime results.

Our analysis now concentrates on relative trends in an effort to minimise the role of absolute uncertainties and poor global resolution in observations and calculations. The following points can be noted: (1) Following curtailments linear trends are immediately established and persist for nearly a decade. (2) The tropospheric trend ratio (Table 1) for curtailed CFC 12 is distinctly different (6–7 against ~2) from that for the other cases, which may present observational and interpretive opportunities for distinguishing any significant tropospheric sinks. (3) Tropospheric trend significance of ±10% may be necessary to distinguish significant tropospheric sinks.

Figures 2 and 3 present existing observational data that seem most representative of background CFC levels[9,11]. We present these data primarily to view trend significance, which is no better than ±(25–50%), even accounting for nothern–southern hemispheric decrements[10]. In fact, because this existing trend data, as well as absolute CFC mixing ratio magnitudes, have sufficient scatter, it is possible that CFC production and release is greater than currently reported and estimated[9,10].

Conclusions

Our investigation was prompted by the prospect of continued indeterminacy of critically significant tropospheric CFC sinks from absolute analyses, and the practical need to make the best use of somewhat randomly collected, sparse and often uncalibrated observational data, coupled with available 1-D theoretical interpretations that incorporate uncertain transport parameterisations with no horizontal resolution. We found, following a source curtailment, that the trend of tropospheric CFC 12 mixing ratios is different by nearly an order of magnitude for 10-yr trophospheric sinks, against no tropospheric sinks. Furthermore, these calculated trends are distinct almost immediately following a source curtailment. Considerations for reducing this mechanism to practical application suggest a number of related points: (1) Concentration on tropospheric measurements may suffice for determining critical CFC sinks, irrespective of atmospheric chemistry details. (2) Tropospheric measurements at permanent, stationary stations would be useful for trend analyses, preferably at several northern and southern

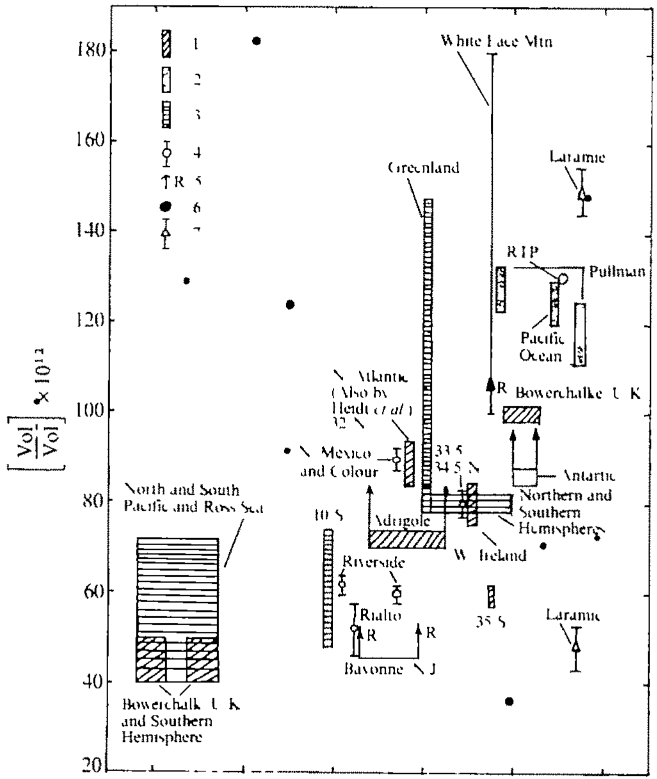

Fig. 3 Observed tropospheric mixing ratios for $CFCl_3$ (CFC 11) Sources 1–7, as in Fig. 2 legend.

latitudes, with many observations taken daily. Siting should maximise the probability of measuring CFC background levels. (3) Observations at each station should include selected tropospheric altitudes, and an array (north, south, east and west) of horizontal sites which may provide a needed measure of local effects. (4) Meaningful trends, inclusive of seasonal variations, could be evaluated station by station, and further processed for both latitudinal and global significance. (5) Absolute calibration for CFC measurements should be established. (6) Natural variabilities in trend data could prove to be too large for 1-D analysis to apply with adequate sensitivity for an explicit determination of possible tropospheric FC sinks. If so, this realisation would be of greatest value earlier, rather than later.

Since this avenue of dynamic analysis is only now put forth for CFCs, a substantial amount of possible future investigation comes immediately to mind. More incisive considerations of CFC data significance and interpretability may be accomplished by analysis of local, meridional and hemispheric trends, in association with global evaluations. These considerations may extend to further analysis of dynamic responses to effective eddy diffusivity variations in 1-D and 2-D, to general atmospheric circulation mechanisms, and to natural radiative variations[24,25].

Several circumstances of gradual against abrupt changes in CFC production, release or substitutions remain for extended investigstion. Correlated and anticorrelated trends of possible CFC substitutions could offer very effective filtering of absolute uncertainties, consistent with the mechanisms presented above.

We thank Dr J. D. Mahlman for helpful discussions.

In cases of β_0 thalassaemia from Ferrara, Italy, the β-globin gene is transcribed into mRNA but no protein is synthesised. For these cases there is no hybridisation data suggesting a globin gene structural mutation. This again demonstrates the diverse molecular events which may cause this prevalent hereditary disease.

β-THALASSAEMIA is an hereditary anaemia in which there is an excess of α-globin over β-globin chain synthesis. In homozygotes for β_0-thalassaemia no β-globin is synthesised, and active haemoglobin is only obtained by the compensatory synthesis of δ- and γ-globin chains. The wide geographical distribution and varying clinical severity of β-thalassaemia indicates the existence of several different lesions at the molecular level, each of which could give rise to the reduced synthesis of β-globin chains[1].

Several cases of β_0-thalassaemia have been described for which there is an absence or reduction in β-globin messenger RNA (mRNA$_\beta$) (refs 2–6), as judged by protein synthesis in a cell-free system or by DNA–RNA hybridisation. Cases from Ferrara, Italy, seem to differ from this more usual pattern, in that it has been reported that β-globin chain synthesis can be activated in reticulocytes both *in vivo* after transfusion and *in vitro* by the addition of post-ribosomal supernatant from normal reticulocyte lysates[7,8]. But so far it has not been demonstrated conclusively by direct measurements that mRNA$_\beta$ is present in such a patient.

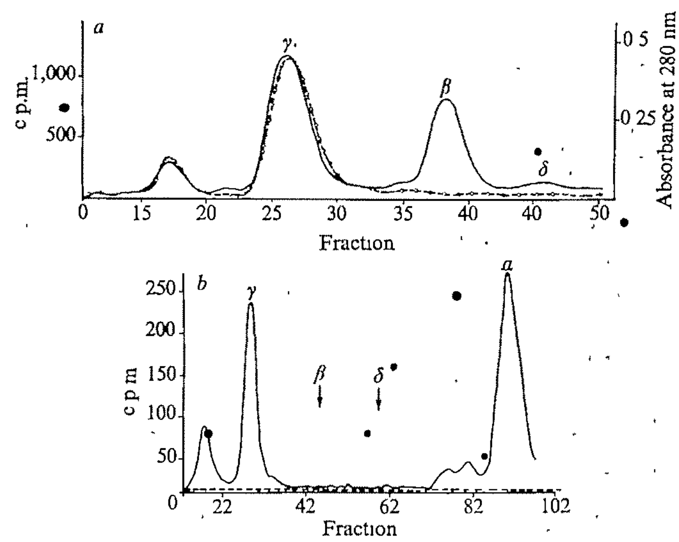

Fig. 1 Globin synthesis in whole cell incubations of reticulocytes from two Ferrara patients. In both cases reticulocytes were incubated with ^{3}H-leucine for 1 h at 37 °C; chain isolation and analysis were carried out on carboxymethylcellulose columns as described previously[8]. Carrier adult globin was added in one case (*a*, patient FR); in the other case (*b*, patient AS) the position of the β- and δ-globin peaks were determined in a parallel run. In both patients, as for the other cases examined, less than 1% of the total amino acid incorporation into globin chromatographs with the β-globin peak. These experiments were performed, in some cases, simultaneously in two laboratories with identical results.

Techniques for preparing complementary DNA (cDNA) probes which can be purified for homology for β-globin genes and mRNA[4] have enabled us to assay directly by hybridisation for mRNA$_\beta$ in several patients with Ferrara thalassaemia both before and after transfusion. Significant levels of mRNA$_\beta$ (up to 12%) have been detected in circulating reticulocytes of patients for whom globin chromatography demonstrates the absence of β-globin chain synthesis. The level of β-globin-specific mRNA sequences in nuclear RNA from the one patient studied is higher still, between 20 and 30%. Ferrara thalassaemia thus differs in molecular pathology from many southern Italian and Asian β_0-thalassaemias, for which the β-globin gene is present but no detectable mRNA is found in the reticulocyte[5], and from South-east Asian α_0-thalassaemia, which is caused by an α-globin gene deletion[9,10]. In other cases of β_0-thalassaemia mRNA$_\beta$ is present, but cannot be translated[23,27].

The conclusions drawn from the DNA–RNA hybridisation experiments will depend on the total absence of β-globin chain synthesis in the cases studied. In each case the total haemoglobin prepared after red-cell lysis was chromatographed on Amberlite and haemoglobin F was eluted[11]. The remaining haemoglobins A and A$_2$ were eluted separately and estimated by absorbance. The sensitivity of this technique allows estimation of as little as 0.2% haemoglobin A in the presence of haemoglobins F and A$_2$. In several cases studied the circulating red blood cells were incubated with ^{3}H-leucine as previously described[7] and the globin chains were extracted and separated on carboxymethylcellulose[12]. This technique is less sensitive but makes possible a direct estimate of β-globin synthesis; as little as approximately 1% β-globin chain can be detected.

In the cases described here there was no haemoglobin A detected on Amberlite chromatography (AS, FR, FB, SM, AM, GC) or on paper electrophoresis (PS) before transfusion. Globin chain chromatography also demonstrated the absence of β-globin chain synthesis (Fig. 1). Therefore it can be concluded, in agreement with our previous findings, that by normal rigorous criteria these patients have a β_0-thalassaemia[13]; γ- and δ-globin synthesis occurs but no β-globin chains are made.

cDNA was prepared as previously described using human globin mRNA as template, oligo(dT) as primer, avian myeloblastosis virus RNA-dependent DNA polymerase as

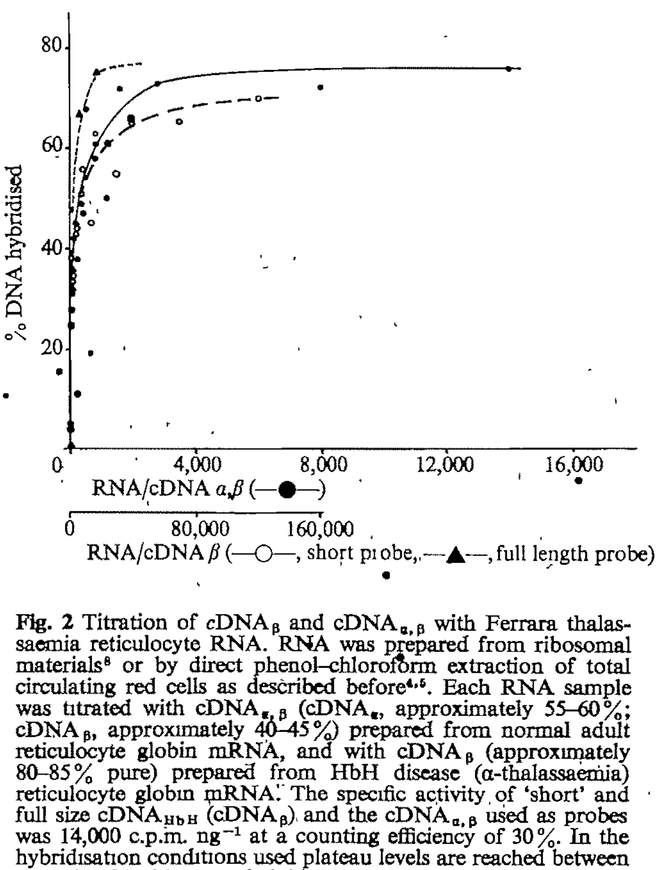

Fig. 2 Titration of cDNA$_\beta$ and cDNA$_{\alpha,\beta}$ with Ferrara thalassaemia reticulocyte RNA. RNA was prepared from ribosomal materials[8] or by direct phenol–chloroform extraction of total circulating red cells as described before[4,6]. Each RNA sample was titrated with cDNA$_{\alpha,\beta}$ (cDNA$_\alpha$, approximately 55–60%; cDNA$_\beta$, approximately 40–45%) prepared from normal adult reticulocyte globin mRNA, and with cDNA$_\beta$ (approximately 80–85% pure) prepared from HbH disease (α-thalassaemia) reticulocyte globin mRNA. The specific activity of 'short' and full size cDNA$_{\text{HbH}}$ (cDNA$_\beta$) and the cDNA$_{\alpha,\beta}$ used as probes was 14,000 c.p.m. ng^{-1} at a counting efficiency of 30%. In the hybridisation conditions used plateau levels are reached between 70 and 80% with normal globin 9S RNA. A constant amount of cDNA$_{\alpha,\beta}$ or cDNA$_\beta$ (18–35 pg) was hybridised with increasing amounts of Ferrara β_0 reticulocyte cytoplasmic RNA, in a volume of 1–2 µl of 50% formamide, 0.5 M NaCl, 25 mM HEPES buffer, pH 6.8, 1 mM EDTA, containing *E. coli* RNA (2.5 mg ml^{-1}). Samples were sealed in silicone-coated glass capilliaries, and incubated at 43 °C for 12–14 d. The percentage of cDNA hybridised was determined by assay with single-strand-specific S1 nuclease, followed by perchloric acid precipitation of hybridised material. Further details are given in previous publications[4,5,8,15]. The ratio mRNA$_\beta$: mRNA$_\alpha$ was calculated by adjusting the abscissa until the initial portions of the hybridisation curves were superimposable, and (after adjusting for the amount of cDNA$_\beta$ present in the cDNA$_{\alpha,\beta}$) taking the ratio from the magnitude of this adjustment. With normal adult globin mRNA the mRNA$_\beta$:mRNA$_\alpha$ ratio obtained by this technique is approximately 0.65. In this case (MA) the ratio mRNA$_\beta$:mRNA$_\alpha$ is 0.05–0.07. Calculations made from initial slopes of hybridisation gave similar values. When the amount of β-mRNA in a preparation (relative to α-mRNA) is as low as 1–20% the initial slope of the hybridisation of the cDNA$_{\alpha,\beta}$ essentially reflects the hybridisation of the cDNA$_\alpha$ component.

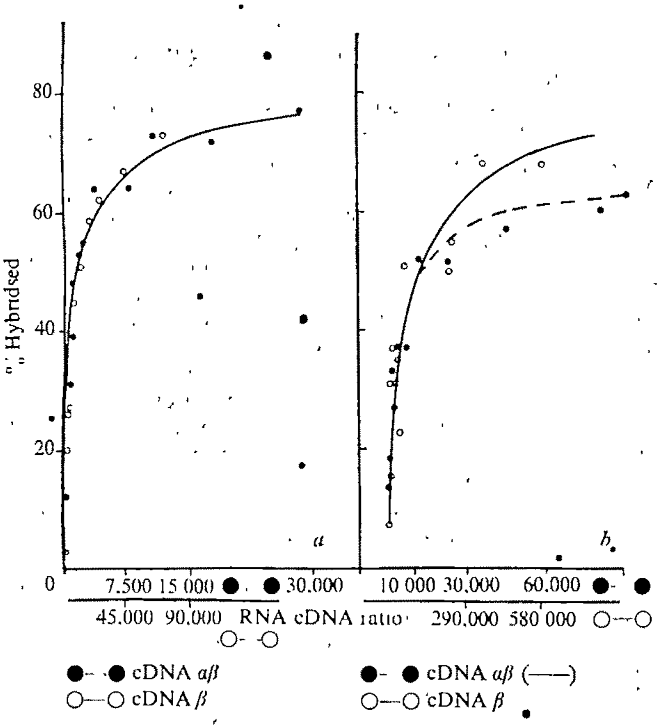

Fig. 3 Titration of bone marrow total nuclear and cytoplasmic RNAs. Cytoplasmic (*a*) and nuclear (*b*) total RNA was prepared from iliac crest bone marrow using a citric acid procedure as described before[15] and titrated with $cDNA_{\alpha,\beta}$ and $cDNA_{\beta}$ (short probe) as described for Fig. 2. In this case (SM) the ratio $cDNA_{\beta}$:$cDNA_{\alpha}$ is 0.10–0.15 for cytoplasmic RNA and 0.20–0.30 for nuclear RNA The ratios required for saturation are much higher for bone marrow than for reticulocytes because of the considerably lower proportion of globin mRNA present[18].

Table 1 $mRNA_{\beta}$ content for different patients

	Patient	%HbA*	%$mRNA_{\beta}$† (in reticulocytes)		
Never transfused					
	AS	<0.2	10–12		
	FR	<0.2	2–3		
	AM	<0.2	2–3 (5–7‡)		
		% β-Globin synthesis	% $mRNA_{\beta}$† (in reticulocytes)	% $mRNA_{\beta}$† in bone marrow cells cytoplasm	nuclei
Transfused					
	PS	31.3	10–20		
	FB§	22.5	12–50		
		14.4	15–20		
	GC	30.8	11–15		
	SM	18.5	—	10–15	20–30

β-Globin synthesis was determined 3–4 weeks after transfusion in intact reticulocyte incubations[6]. The values reported are relative to α-globin synthesis.

* Relative to total haemoglobin.

† Relative to $mRNA_{\alpha}$. In all experiments reported, $cDNA_{HbH}$ hybridisation went essentially to completion (68–80%).

‡ Determined on RNA extracted from ribosomal material[6].

§ Determinations were on blood samples taken after two different transfusions.

enzyme, and ^{3}H-dCTP as the only labelled deoxynucleotide triphosphate[4,5,8,15,16]. For most of the experiments reported, 'short' cDNAs (complementary to the 3′-end half of the mRNA) were prepared; however, in a few instances full size cDNAs were used[17]. Human globin mRNA was obtained from reticulocytes from a subject with a non-thalassaemic haemolytic anaemia ($mRNA_{\alpha,\beta}$) and from a patient with haemoglobin H disease (α thalassaemia), in which the proportion of $mRNA_{\beta}$ is already increased to approximately 80–85% ($mRNA_{\beta}$). These mRNAs were transcribed to give $cDNA_{\alpha,\beta}$ and $cDNA_{HbH}$, which were used directly as probes for $mRNA_{\alpha}$ and $mRNA_{\beta}$ sequences in various RNA preparations from the patients with β_0-thalassaemia (Ferrara). The proportion of $mRNA_{\beta}$ relative to $mRNA_{\alpha}$ was estimated by comparing the initial slopes of the hybridisations with the cDNAs by adjusting the scale of the x axes to make the two hybridisation curves superimposable. The untransfused patients studied (three cases) showed $mRNA_{\beta}$ levels from 2 to 12% in reticulocytes as a proportion of $mRNA_{\alpha}$ (Fig. 2). In four patients $mRNA_{\beta}$ was determined 3–4 weeks after transfusion, when β-globin synthesis was demonstrable in intact reticulocyte incubation. In three of these cases the reticulocyte $mRNA_{\beta}$ levels were between 10 and 20%. In the fourth case a bone marrow sample was examined; the proportion of nuclear RNA sequences hybridising to $cDNA_{\beta}$ was found to be two or three times higher than in cytoplasmic RNA (Fig. 3). The level of $mRNA_{\beta}$ in the circulating reticulocytes of the same patient 5 weeks after transfusion, when β-globin synthesis in intact erythrocytes had become undetectable, was 2%. The results are summarised in Table 1.

The methods for estimating the absolute amounts of $mRNA_{\beta}$ relative to $mRNA_{\alpha}$ are somewhat imprecise, particularly because the calculation depends on the difference between hybridisation to $cDNA_{\beta}$ and to $cDNA_{\alpha,\beta}$ and might give a maximum error of as much as 30% for each value determined. But the fact that the hybridisations go to completion compared with hybridisations to normal reticulocyte RNA for each probe at usual low RNA: cDNA ratios demonstrates the presence of sequences indistinguishable from $mRNA_{\beta}$ by hybridisation criteria in circulating reticulocytes from these cases of β_0-thalassaemia In this respect we wish to stress that, even when a full size $cDNA_{HbH}$, is used, protection of this probe from S_1 nuclease to the same extent as with normal $mRNA_{\alpha,\beta}$ is obtained. Even allowing for errors, the $mRNA_{\beta}$ levels determined are very much higher than the maximum level of β-globin chain synthesis which might have remained undetected, if any, in the untransfused cases (Fig. 2). No $mRNA_{\beta}$ could be detected in identical experiments run in parallel with cytoplasmic RNA from two non-Ferrara cases of β_0-thalassaemia, one of which was examined 3–4 weeks after transfusion[5]; levels of less than 1% of β-mRNA-like sequences have been found consistently in a series of 10 β_0-thalassaemic patients of non-Ferrara origin (P.C., B.G. and S.O., unpublished observations); thus a contribution of $mRNA_\delta$ to hybridisation could not explain the results obtained, as the haemoglobin A_2 levels were similar in all cases.

The thermal stability of the hybrid between Ferrara RNA (from transfused and untransfused patients) and $cDNA_{HbH}$ was 2 °C lower than that of the hybrid between normal 9S mRNA and $cDNA_{HbH}$ (Fig. 4). This confirms that the hybridisation observed is due to $mRNA_\beta$ sequences or sequences very similar to $mRNA_\beta$; the smooth form of the melting curve argues for accurate hybrid formation along the entire sequence. The nucleotide divergence corresponding to a ΔT_m of 2 °C is between 0.5 and 1.0%[18–21]; however, the authors are not sure the difference is significant, as thalassaemic mRNA samples are often degraded owing to difficulties in collection. An effect on melting temperature of this magnitude has been demonstrated for the hybridisation of short rabbit globin mRNA transcripts to cDNA[22]. The melting behaviour of a $cDNA_\beta$–$mRNA_\delta$ hybrid is not yet known.

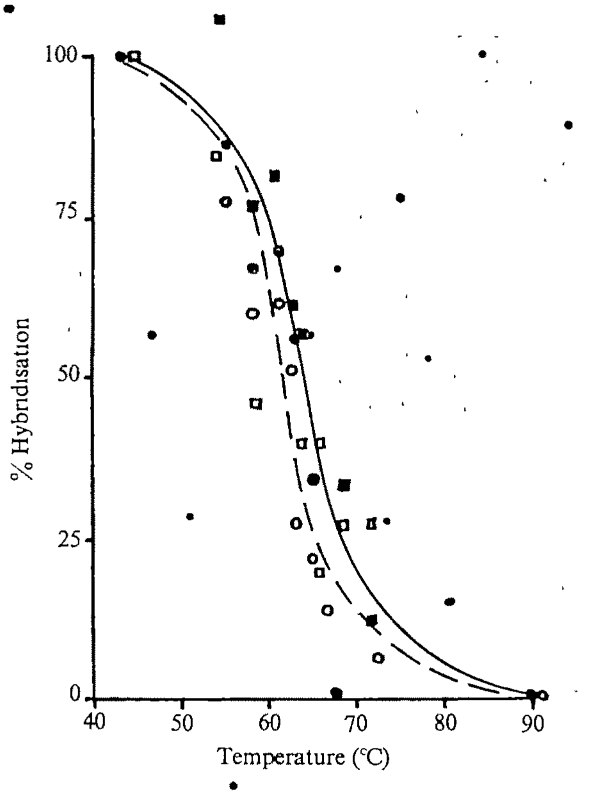

Fig. 4 Melting profiles of normal and Ferrara globin mRNA to $cDNA_\beta$. 20 pg 'short' $cDNA_{HbH}$ were hybridised in individual capillaries with 400 pg normal globin 9S RNA or either 0.9 μg total RNA (AM, ribosomal) or 5.6 μg total RNA (GC) in 1 μl hybridisation buffer at 43 °C for 13 d. Both AM and GC were shown to be β_0 thalassaemics by Amberlite chromatography. At the end of the incubation, capillaries were heated to the indicated temperature, quickly cooled to 0 °C, diluted with S1 nuclease assay buffer and frozen until assayed with S1 nuclease. Data are expressed as percentage of maximum hybridisation obtained; background S1 resistance is subtracted. In this experiment $cDNA_{HbH}$ hybridised to 73% with normal 9S mRNA and to 65% with Ferrara thalassaemia RNA ● and ■, Normal RNA; ○, RNA from GC; □, RNA from AM.

Hybridisation to chain-specific cDNA demonstrates the presence of homologous mRNA sequences, and because there is little evidence of cross hybridisation in the globin gene system[4,5], these sequences demonstrated with $cDNA_\beta$ arise from transcription of the β-globin gene. In the cases considered at least some complete β-globin mRNA molecules must be present, for full size $cDNA_{HbH}$ can hybridise to completion to Ferrara mRNA.

Attempts to demonstrate synthesis of β-globin directed by isolated mRNA in a heterologous cell-free system have been disappointing, although Pritchard *et al.*[14], using RNA from patient BS, reported the synthesis of a fraction with the chromatographic characteristics of β-globin chains. Because of insufficient radioactivity in the peptides Pritchard *et al.*[14] were not able to identify the peak which chromatographs with β globin unequivocally by fingerprint analysis. Further experiments to this end will be undertaken when enough Ferrara thalassaemia mRNA becomes available.

In Ferrara thalassaemia, apparently normal $mRNA_\beta$ found in erythroid cells which hybridises to $cDNA_\beta$, can be activated *in vitro* by the addition of normal post-ribosomal supernatant[7] and can be activated *in vivo* by transfusion with normal blood[6]; the latter finding has been confirmed in the patients studied in the work reprinted here. The untranslated β-globin mRNA apparently decays faster than normal, as indicated by the higher level of $mRNA_\beta$ found in bone marrow relative to reticulocytes, and by the lower levels of reticulocyte $mRNA_\beta$ found when there has been no transfusion with respect to post-transfusional conditions, when β-globin synthesis occurs. It has been shown that high levels of untranslated $mRNA_\beta$ are present in β_0-thalassaemia among Americans of Chinese descent[23], while some $\delta\beta_0$-thalassaemias and hereditary persistence of foetal haemoglobin are caused by gene deletion[17,24–26]. There are many cases of β_0-thalassaemia where the gene for β globin is present but $mRNA_\beta$ is absent (ref. 5 and P. Tolstoshev and S.O., unpublished observations).

B. Forget (personal communication) has reported similar findings recently, using RNA extracted from samples of blood from one of the patients described here. Ramirez *et al.*[26] have reported the isolation of mRNA from Ferrara thalassaemic blood which hybridises incompletely with $cDNA_\beta$ and have postulated a structurally abnormal $mRNA_\beta$ which does not hybridise to completion. Our results do not agree with theirs.

We thank Professor D. J. Weatherall for advice, many clinical colleagues for help in obtaining pathological materials, and Dr J. Beard for purified reverse transcriptase. The Centro di Studi Biochimici sul Morbo di Cooley, Cassa di Risparmio di Ferrara is supported by the Italian CNR, by the Regione Emilia-Romagna, by Regione Veneto and by NIH.

5′-Terminal structure and mRNA stability

Yasuhiro Furuichi, Alba LaFiandra & Aaron J. Shatkin
Roche Institute of Molecular Biology, Nutley, New Jersey 07110

Reovirus mRNAs with 5′-terminal m⁷GpppG^m or GpppG are more stable than mRNA containing unblocked ppG 5′-ends when injected into Xenopus laevis *oocytes or incubated in cell-free protein synthesising extracts of wheat germ and mouse L cells. The greater stability of mRNA with blocked 5′ termini is not dependent upon translation but seems to result from protection against 5′-exonucleolytic degradation.*

Most eukaryotic mRNAs including reovirus mRNA contain a blocked, methylated 5′-terminal 'cap', $m^7G(5')ppp(5')X$ (ref. 1). The presence of this structure is required for efficient translation of reovirus mRNA in a wheat germ protein synthesising extract[2]. It also facilitates the function of other viral and cellular mRNAs in cell-free systems derived from animal and plant cells[3–7]. The cap acts at the level of initiation[1], apparently by promoting the formation of ribonuclease-resistant, stable complexes between mRNA and ribosomes[8,9].

It was of interest to determine whether the stability of mRNA is also affected by its 5′-terminal structure. Several eukaryotic mRNAs were previously found to be more stable after microinjection into *Xenopus laevis* oocytes than ribosomal RNAs[10] which have phosphorylated, unblocked 5′ ends. Capped mRNAs can be 'unblocked' by β-elimination, that is, chemical removal of the 5′-terminal m^7G. Although this procedure decreases the translation of treated mRNA, it also alters the 3′ terminus and possibly internal sites in the RNA chains. In an attempt to avoid these complications in studies on the role of the cap in eukaryotic protein synthesis, we established conditions for the selective *in vitro* synthesis of reovirus mRNA with 5′-termini of three different types: unblocked (ppG), blocked (GpppG) and capped (m^7GpppG^m) (ref. 11). We report here that reovirus mRNAs with blocked or capped 5′ termini are more stable than unblocked or β-eliminated viral mRNAs in *X. laevis* oocytes and protein synthesising extracts of wheat germ and L cells. In reticulocyte lysates, however, the mRNAs are similarly stable. In addition, the results suggest that unblocked mRNA is degraded exonucleolytically from the 5′-end.

Increased stability of reovirus mRNA containing blocked 5′ termini

Radioactive reovirus mRNAs were synthesised in the presence of α-^{32}P-UTP under previously specified conditions[11] designed to obtain molecules with predominately (>93%) one type of 5′-end. In addition to the three types noted above, viral mRNAs with 5′-terminal pppG and $pppG^m$ were prepared by β-elimination of blocked and capped mRNAs, respectively. For stability measurements, ^{32}P-labelled samples were microinjected into *X. laevis* oocytes[10]. At the indicated time intervals, the oocytes were homogenised and the lysates analysed for total and acid-precipitable radioactivity. mRNAs with blocked 5′ termini were apparently more stable than those with unblocked, phosphorylated 5′ ends (Fig. 1). For example, 8 h after injection of mRNAs containing GpppG or m^7GpppG^m, ~55% of the intracellular radioactivity remained acid-precipitable. By contrast, values of 20–25% were obtained for the three mRNA samples with unblocked 5′ termini, that is, ppG, pppG and $pppG^m$.

Radioactive material was re-isolated from oocytes at intervals after injection of ^{32}P-labelled mRNA and analysed by sedimentation velocity centrifugation. At each time the acid-precipitable radioactivity was present mostly in full-length viral mRNA rather than RNA fragments. Sedimentation profiles of the untreated samples obtained before injection into oocytes included the large (l), medium (m), and small (s) size classes of

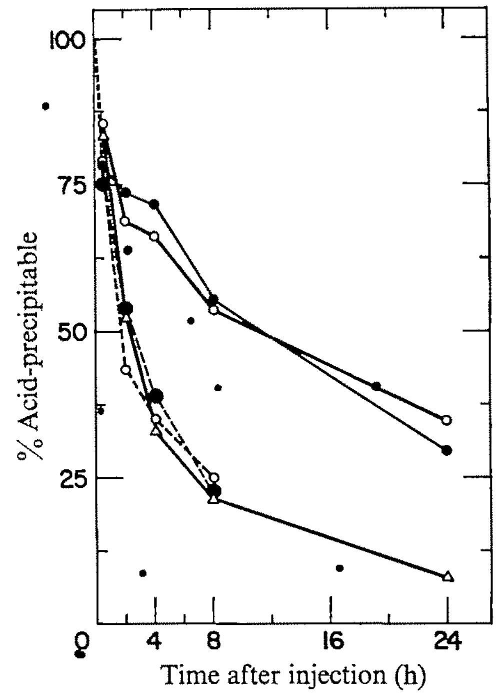

Fig. 1 Degradation of reovirus mRNA injected into *X. laevis* oocytes. Reovirus mRNA was synthesised *in vitro* by the virion-associated RNA polymerase in the presence of α-^{32}P-UTP in conditions[11] that yielded ^{32}P-labelled products (final specific activity = 1.2×10^6 c.p.m. per μg RNA) containing 5′-terminal 94% ppG (with 6% GpppG), 93% GpppG (with 7% ppG), or >94% m^7GpppG^m. Aliquots of the last two samples were oxidised with periodate and treated with aniline to obtain mRNA with 5′-terminal pppG and $pppG^m$ (ref. 21). The β-elimination was >90% complete as monitored with ^{3}H-methyl-labelled mRNA. RNAs were purified by Sephadex G-100 gel filtration, passed through sterile 0.22-μm filters, reprecipitated with ethanol and dissolved in H_2O at concentrations of 3.3 μg μl^{-1}. For each time point, 10 oocytes were injected with 50 nl of RNA solution per oocyte and incubated at room temperature in 5 ml of amphibian media consisting of 15 mM Tris buffer *p*H 7.4, 88 mM NaCl, 1.3 mM KCl, 0.7 mM $CaCl_2$ and 0.8 mM $MgCl_2$ as suggested by Dr L. Burzio, Rockefeller University. At the indicated times, oocytes were removed, washed three times with 2 ml of media, resuspended in 0.2 ml of 50 mM Tris-HCl, *p*H 7.6 containing 0.1 M NaCl, 5 mM EDTA, and 0.5% sodium dodecyl sulphate and homogenised in a Dounce homogeniser. The lysates were extracted with an equal volume of redistilled, H_2O-saturated phenol, centrifuged (3000 r.p.m., 10 min), and the aqueous layers were assayed for total and acid-precipitable radioactivity by counting aliquots directly in Aquasol and on Millipore filters after precipitation in 5% trichloroacetic acid. Because the recovery of intracellular radioactivity varied (23–79% of the estimated amount of micro-injected mRNA) presumably due to leakage, values were normalised by expressing them as a percentage of recovered c.p.m. that were acid-precipitable. mRNAs with 5′-terminal m^7GpppG^m (●), GpppG (○), ppG (△), $pppG^m$ (●--●) and pppG (○--○).

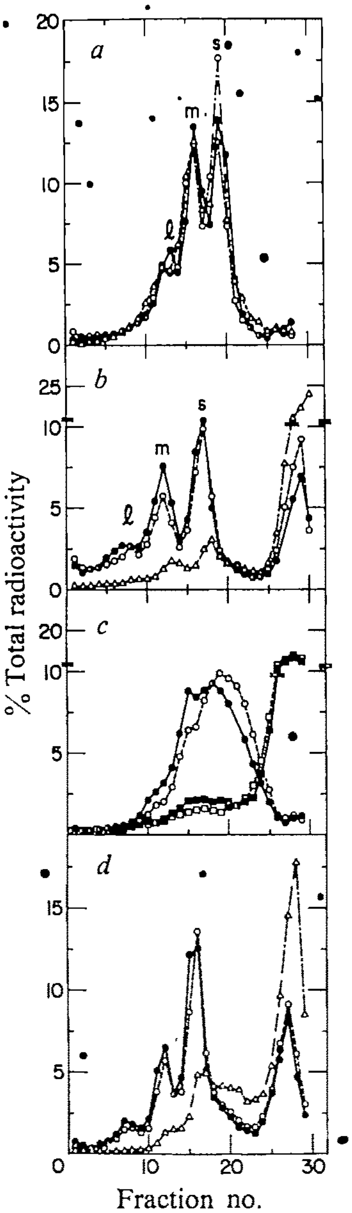

Fig. 2 Sedimentation analysis of reovirus mRNA before and after incubation in oocytes or wheat germ extract. *a*, mRNA synthesised in the presence of α-^{32}P-UTP was purified by gel filtration and sedimented in 5–30% glycerol gradients (20 mM Tris-HCl, *p*H 7.6, 0.1 M NaCl, 1 mM EDTA; SW41–33,000 r.p.m., 16 h). Fractions of 0.4 ml were collected and counted in Aquasol. *b*, The mRNAs containing different types of 5′-ends were injected into oocytes, reisolated after 8 h and analysed as in (*a*). *c*, Blocked and capped 5′-ends of mRNA were converted to 5′-pppG and pppG^m, respectively, by β-elimination[11]. The treated mRNAs were sedimented before (pppG^m, ●; pppG, ○), and after incubation (pppG^m, ■; pppG □) for 8 h in oocytes. *d*, mRNAs synthesised with α-^{32}P-UTP (1 μg, 46–55 × 10^3 c.p.m.) were incubated in wheat germ extract for 10 min at 26 °C. Radioactivity was then recovered by phenol extraction and analysed as in (*a*). For panels *a*, *b* and *d*, mRNAs with 5′-terminal m^{7}GpppG^m (●); GpppG (○); ppG (△).

reovirus mRNA and no slowly sedimenting material (Fig. 2*a*). Following incubation there was a progressive reduction in the proportion of radioactivity in viral mRNA and a corresponding increase in low molecular weight material which was acid-soluble. At all times, however, the fraction of radioactivity sedimenting as intact mRNA was greater for the samples that contained blocked as compared to unblocked 5′ termini. This can be seen in the sedimentation patterns of samples extracted 8 h after injection (Fig. 2*b*). Sixty per cent of the radioactivity in the mRNAs with 5′-terminal m^{7}GpppG^m or GpppG sedimented in the l, m and s positions while less than 20% of the mRNA containing 5′-ppG remained undegraded. Similar results were obtained with β-eliminated mRNAs containing pppG^m and pppG at the 5′-ends (Fig. 2*c*). Although the chemically-treated RNAs were not resolved into the three size classes, possibly because some chains were nicked during β-elimination, the preparations before injection contained very little radioactivity sedimenting at the top of the gradient. By 8 h after injection, more than 75% of both RNAs had been degraded to slowly sedimenting material. Since mRNAs terminating in pppG^m and ppG showed similar rates and patterns of degradation (Figs 1, 2*b* and *c*), an increase in the number of 5′-phosphates and 2′-*O*-methylation of the 5′-terminal residue did not stabilise the mRNA.

Degradation of the various mRNAs in each case resulted in low molecular weight products and no skewing of the mRNA peaks, suggesting exo- rather than endonucleolytic cleavage. This effect can be seen most clearly with mRNA that had not been chemically treated (Fig. 2*b*). Allende *et al.*[10] also observed that the stable fraction of *Dictyostelium* mRNA extracted from *Xenopus* oocytes 24 h after injection cosedimented with uninjected marker mRNA. Our findings that the 5′-unblocked

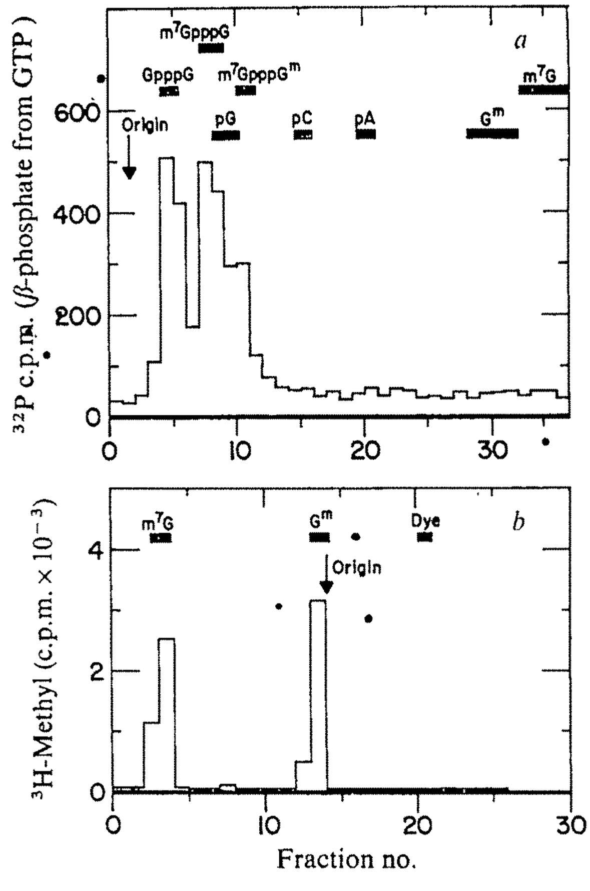

Fig. 3 Analysis of 5′-terminally labelled mRNA after incubation in oocytes. *a*, Reovirus mRNA was synthesised *in vitro* in the presence of β,γ-^{32}P-GTP, *S*-adenosylhomocysteine and inorganic pyrophosphatase to obtain products with 5′-terminal Gpp*pG (ref. 11). The purified mRNA was microinjected (a total of 1 μg and 16,000 c.p.m. into 50 oocytes), incubated for 9 h, re-extracted, digested with P$_1$ nuclease and alkaline phosphatase and analysed by paper chromatography in isobutyric acid—0.5 M NH$_4$OH (10/6 v/v)[12]. *b*, ^{3}H-methyl-labelled mRNA containing 5′-terminal m^{7}GpppG^m was injected (50 oocytes each with 50 nl, 0.08 μg, 1,200 c.p.m.) and after 24 h was re-isolated, digested with P$_1$ nuclease and analysed by high voltage paper electrophoresis at *p*H 3.5 (ref 12). The enzyme-resistant, ^{3}H-labelled blocked structures migrating as a peak close to pG were eluted, digested with nucleotide pyrophosphatase and phosphatase and re-analysed by electrophoresis (60 V cm^{-1}, 45 min). Marker compounds were located under ultraviolet light, and 1-cm strips were cut and counted in toluene-based scintillant[12].

mRNAs are less stable than blocked mRNAs, together with the earlier report[10], suggest that mRNA degradation in oocytes occurs from the 5′-end by an exonucleolytic, processive mechanism.

Studies of the fate of eukaryotic mRNAs in *X. laevis* oocytes showed that puromycin treatment decreased stability, and it was proposed that association with ribosomes affords some protection of mRNA against nucleolytic degradation[10]. Because methylation of reovirus mRNA promotes initiation complex formation *in vitro*[1–8], we tested whether the 5′-terminal GpppG in injected viral mRNA was converted to m^{7}GpppG$^{(m)}$ by methyl transferase(s) in oocytes. mRNA was synthesised with β-γ-^{32}P-GTP as radioactive precursor in order to label specifically the blocked 5′-terminal structure, Gpp*pG (refs 11, 12). In the synthetic conditions used[11], the mRNA contained 5′-Gpp*pG (93%) and small (7%) amounts of 5′-p*pG. The RNA was injected into oocytes, recovered after 9 h and analysed as described in the legend to Fig. 3 to identify the 5′-terminal structure. About 40% of the ^{32}P-labelled, blocked 5′-termini remained unmethylated and migrated in the position of GpppG (Fig. 3*a*). The rest of the Gpp*pG 5′-ends were methylated, however, and enzyme treatment of the mRNA yielded a mixture of m^{7}Gpp*pG and m^{7}Gpp*pG^m. We conclude that *X. laevis* oocytes, like protein synthesising extracts from plant and animal cells[2,4–7], contain enzyme activities that methylate the 5′-end of reovirus mRNA and presumably other mRNAs as well. Because the blocked reovirus mRNA in oocytes was only partially methylated at the 5′-end (~60% conversion of GpppG to m^{7}GpppG$^{(m)}$ at 9 hr), this event cannot account for stability since the degradation kinetics of unmethylated, blocked mRNA and capped mRNA are almost identical during the 24 h after microinjection and both mRNAs are equally more stable than unblocked mRNA (Fig. 1). Consistent with this conclusion, blocked mRNA was also more stable than unblocked mRNA in wheat germ protein synthesising extracts in conditions that prevented methylation.

In order to determine if caps in mRNA turn over, reovirus mRNA synthesised in the presence of ^{3}H-methyl-*S*-adenosylmethionine and labelled exclusively in the 5′-terminal m^{7}GpppG^m was injected into oocytes. After 24 h, the RNA was reisolated, digested with P$_1$ nuclease and phosphatase, and analysed by paper electrophoresis[12]. Over 90% of the radioactivity migrated in the position of blocked structures (data not shown). This material was eluted, digested with nucleotide pyrophosphatase and alkaline phosphatase, and re-analysed by electrophoresis (Fig. 3*b*). Radioactivity was equally distributed between two ^{3}H-methyl-labelled components migrating in the positions of 7-methylguanosine (m^{7}G = 3,680 c.p.m.) and 2′-*O*-methylguanosine (G^m = 3,690 c.p.m.). Thus, both methylated residues in caps were conserved and the 5′-terminal m^{7}G did not turn over following injection of reovirus mRNA into *X. laevis* oocytes. Although an enzyme activity that cleaves m^{7}G-containing cap structures has been detected in animal cell extracts, it did not hydrolyse caps in intact mRNA[13]. A novel phosphodiesterase that cleaves pyrophosphate linkages in mRNA has been purified from tobacco cells[14]. In our studies, however, there was no evidence for differential turnover of caps when reovirus ^{3}H-methyl-labelled mRNA was incubated for 90 min in conditions of protein synthesis in wheat germ extract and then analysed as in Fig. 3*b* (unpublished results). As reported for cellular mRNAs in mouse kidney[15] and L cells[16], caps in reovirus mRNA apparently decay with the mRNA chain when incubated in *X. laevis* oocytes or wheat germ extract.

Reovirus mRNA degradation independent of translation in wheat germ extract

Reovirus mRNAs with blocked or capped 5′-termini are more stable than unblocked mRNAs in oocytes, consistent with 5′-exonucleolytic degradation. Although *X. laevis* oocytes are useful for *in vivo* studies on mRNA stability and function[10,17], it is not yet known if reovirus mRNAs are translated in this system. To investigate the relationship between translation and the stabilities of mRNAs with variable 5′-terminal structures, studies were performed using wheat germ protein synthesising extract which was shown previously to translate reovirus mRNA containing 5′-terminal m^{7}GpppG^m (ref. 2). The same viral mRNA with 5′-terminal GpppG or ppG functions poorly or not at all in protein synthesis when the conversion of GpppG ends to m^{7}GpppG by wheat germ endogenous methyl transferase(s) is prevented by addition of *S*-adenosylhomocysteine[2]. While the presence of this methylation inhibitor blocks translation of unmethylated reovirus mRNA in wheat germ extract, it does not affect protein synthesis directed by mRNA that is pre-methylated during transcription. As found before, and shown in Fig. 4*a*, only capped mRNA was efficiently translated in the presence of *S*-adenosylhomocysteine. Under the same conditions, the relative mRNA stabilities in wheat germ extract were similar to those found with microinjected oocytes, that is, the capped and blocked mRNAs were both more stable than unblocked mRNA (Fig. 4*b*). Since capped mRNA (that is, blocked and methylated) forms stable complexes with wheat germ ribosomes while blocked but unmethylated mRNA does not[8], the similar stability observed for these two types of mRNAs is not due to protection by association with ribosomes. Thus, increased stability seems to be an intrinsic property of mRNAs with blocked 5′-terminal structures. From the results shown in Figs 4*a* and *b*, it seems that 5′-blocking without methylation is sufficient to enhance reovirus

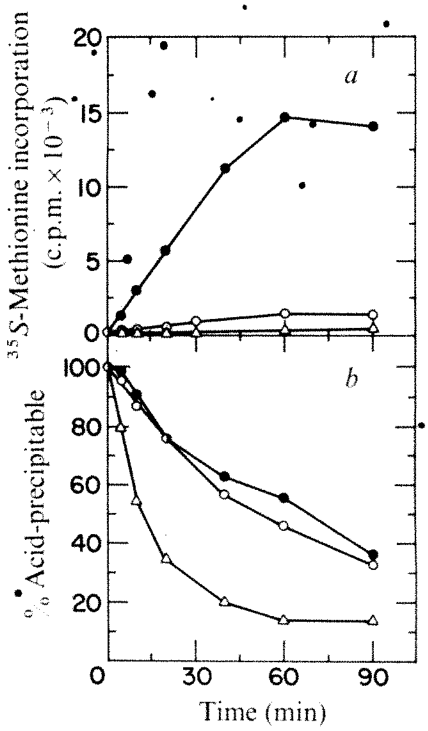

Fig. 4 Translation and degradation of reovirus mRNAs in wheat germ extract in the presence of the methylation inhibitor, *S*-adenosylhomocysteine (Adohcy). *a*, For protein synthesis the incubation mixture (50 µl) contained 12 mM HEPES buffer (*p*H 7.3), 3 mM Mg acetate, 1 mM ATP, 0.05 mM GTP, 5 mM creatine phosphate, 10 µg creatine phosphate kinase, 75 mM KCl, 2 mM dithiothreitol, 100 µM Adohcy, ^{35}S-methionine (10 µCi, 250 Ci mol^{-1}), 0.01 mM of each of the other 19 amino acids, 1 µg reovirus mRNA, and wheat germ extract equivalent to 215 µg protein prepared as before[2]. Incubation was at 26 °C, and 5 µl aliquots were collected in 0.2 ml 5% trichloroacetic acid, heated for 10 min at 90 °C, and the acid-precipitable radioactivity collected on Millipore filters was counted in toluene-based scintillant. *b*, Degradation was measured in the same reaction conditions, except that ^{35}S-methionine was replaced by 0.01 mM non-radioactive methionine and ^{21}P- labelled reovirus mRNAs (1 µg, 110–130 × 10^3 c.p.m.) prepared with α-^{23}P-UTP were used. Incubation was at 26 °C; 5-µl aliquots were extracted and radioactivity precipitated in 5% trichloroacetic acid was measured as described in (*a*). mRNAs contained 5′-terminal m^{7}GpppG^m (●), GpppG (○) and ppG (△).

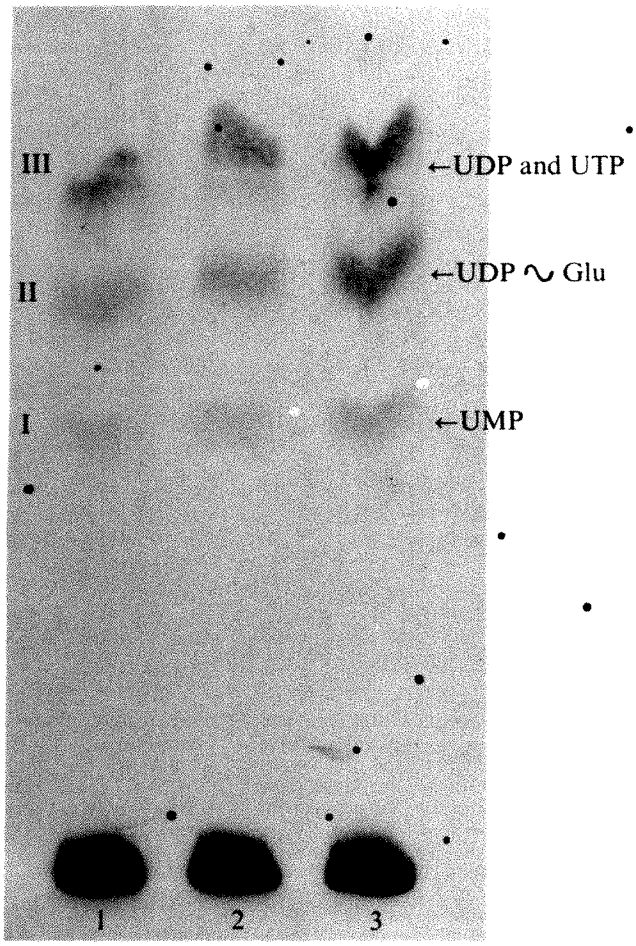

Fig. 5 Analysis of degradation products of reovirus mRNA. Reovirus mRNAs labelled internally with α-^{32}P-UMP were incubated for 10 min in wheat germ extract in the conditions described for Fig. 4*b*. Radioactive materials were recovered from reaction mixtures by phenol extraction and analysed by high voltage paper electrophoresis (50 V cm^{-1}, 50 min) in 10% pyridine-acetate buffer (*p*H 3.5) with marker compounds. Total radioactivity shown in the autoradiogram in tracks 1, 2 and 3 was 110, 120, and 108 × 10^3 c.p.m., respectively. The distribution of radioactivity in each track determined by direct counting of each spot after cutting the paper, was: track 1—origin 87%, band I, 1.7%; band II, 5% and band III, 6.3%. Track 2—origin 83%; band I, 2%; band II, 6.6% and band III, 8.4%. Track 3—origin 60%; band I, 5%; band II, 15% and band III, 20%. Reovirus mRNAs in tracks 1, 2 and 3 contained 5′-terminal m^{7}GpppG^m, GpppG, and ppG, respectively. UDP ~Glu is an abbreviation for uridine diphosphate glucose.

mRNA stability, but translation in wheat germ extract depends on the presence of the methylated blocked structures, m^{7}GpppG^m. The more rapid degradation of unblocked reovirus mRNAs, which have the same sequence and size as blocked or capped mRNA but a different 5′-terminal structure, suggests that mRNA is degraded exonucleolytically from the 5′-end.

5′-Exonuclease cleavage of unblocked mRNA

Reovirus unblocked mRNA was less stable than 5′-blocked mRNA in microinjected oocytes or in wheat germ cell-free extract (Figs 1, 4*b*). When unblocked radioactive mRNA was re-extracted after incubation for 8 h in oocytes, the radioisotope was present in full-size mRNA and in low molecular weight degradation products (Fig. 2*b*). The same results were obtained when mRNA was incubated in wheat germ extract for 10 min and subsequently analysed by velocity sedimentation in a glycerol gradient (Fig. 2*d*). Little radioactivity was observed in products of intermediate size and most of the degraded material sedimented at the top of the gradient. The low molecular weight products were characterised by paper electrophoresis (Fig. 5). Radioactive material analysed after incubation of ^{32}P-labelled mRNA in wheat germ included the mRNA at the origin and three fast-migrating bands but no intermediate spots in the position of oligonucleotides, CMP, AMP, or GMP. The compound in band I corresponds to 5′-UMP. Band III was eluted and identified as a mixture of UDP (32%) and UTP (68%) by paper chromatography with marker compounds in isobutyric acid–0.5 M NH$_4$OH (10:6 v/v). The component in band II migrated in the position of UDP-glucose or UDP-galactose and the ^{32}P-phosphate present in this material was resistant to hydrolysis by alkaline phosphatase. We have not identified the compound(s) in band II, but it has a net charge of −2 by DEAE-cellulose chromatography and can be enzymatically synthesised from ^{3}H-UTP in wheat germ extract, consistent with it being a UDP-sugar derivative. In addition, there is a clear precursor–product relationship between the 5′-UMP (band I), the UDP and UTP (band III) and the presumptive UDP-sugar (band II). When ^{3}H-labelled 5′-UMP (360 pmol, 15 μCi) was incubated for 20 min in wheat germ extract, 54% of the input radioactivity was incorporated into the presumptive UDP-sugar compound and 29% into a mixture of UDP and UTP. By contrast, the presumptive UDP-sugar yielded no 5′-UMP, UDP, or UTP on incubation in wheat germ extract. Thus, the primary degradation product of mRNA labelled with α-^{32}P-UTP was 5′-UMP which in wheat germ was further

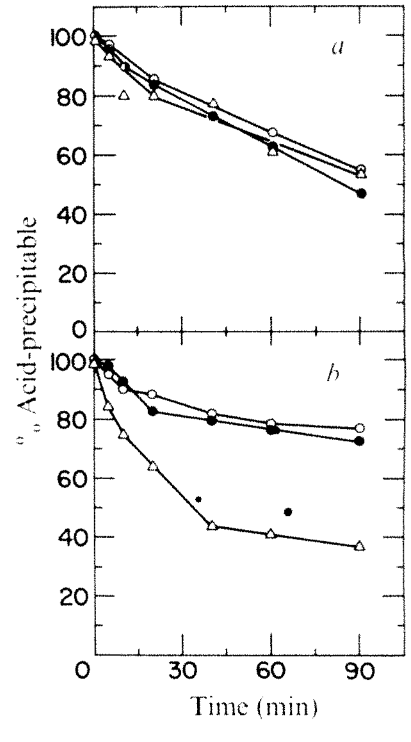

Fig. 6 Test for exonuclease activity in rabbit reticulocyte lysate and mouse L cell extract. Reovirus mRNAs labelled internally with α-^{32}P-UMP (20 μg ml^{-1}, 100–120 × 10^3 c.p.m.) were incubated at 26 °C in conditions used for *in vitro* protein synthesis. *a*, Reticulocyte lysate: the reaction mixture (50 μl) contained 12 mM HEPES buffer (*p*H 7.5), 75 mM KCl, 1.5 mM Mg acetate, 0.8 mM ATP, 0.16 mM GTP, 100 μM Adohcy, 10 mM creatine phosphate, 11 μg creatine phosphate kinase, 5 mM dithiothreitol, 0.1 mM each of 20 amino acids, 20 μg ml^{-1} haemin, 1 μg ^{32}P-labelled reovirus mRNA and lysate equivalent to 2.4 mg protein (provided by W. F. Anderson). *b*, L cell protein synthesising extract: the mixture contained 20 mM HEPES (*p*H 7.6), 120 mM KCl, 5 mM Mg acetate, 6 mM β-mercaptoethanol, 1 mM ATP, 0.2 mM GTP, 100 μM Adohcy, 0.1 mM each of 20 amino acids, 5 mM dithiothreitol, 10 mM creatine phosphate, 10 μg creatine phosphate kinase, and L cell extract equivalent to 252 μg protein (provided by G. Koch). Acid-precipitable radioactivity was assayed as for Fig. 4*b*. mRNAs contained 5′-terminal m^{7}GpppG^m (●), GpppG (○) and ppG (△).

metabolised by the route UMP → UDP → UTP → UDP-sugar. The reovirus mRNA degradation products from *X. laevis* oocytes yielded the same four uridine derivatives when subjected to electrophoresis, and the primary mRNA degradation products in oocytes also are probably 5′-mononucleotides. These observations suggest that the exonuclease processively cleaves unblocked mRNA in a 5′ to 3′ direction yielding 5′-mononucleotides. Confirmation of these characteristics will require studies of the purified enzyme(s).

Like *Xenopus* oocytes and wheat germ extract, L cell protein synthesising extract also contains an enzyme activity that degrades unblocked reovirus mRNA more rapidly than blocked or capped mRNA (Fig. 6*b*). In contrast, we did not detect a differential breakdown of unblocked mRNA in reticulocyte lysate incubated at a 10-fold higher ratio of protein to mRNA than used for L cell extracts (Fig. 6*a*). It will be of interest to determine whether mRNA degrading activities with similar properties exist generally in eukaryotic cells and if so, whether they are involved in mRNA turnover and regulation of cell division and differentiation.

Discussion

In this report, reovirus mRNAs with different types of 5′-termini were used to demonstrate that, in addition to a role in the initiation of protein synthesis, cap structures have an important stabilising effect on mRNA. In accordance with this function, and consistent with the lower stability of unblocked reovirus mRNA in *Xenopus laevis* oocytes and extracts of wheat germ and L cells, a nuclease activity which apparently cleaves unblocked RNA exonucleolytically and probably processively was detected in the amphibian, plant, and mammalian systems. Rabbit reticulocyte lysate was an exception and contained little or no nuclease activity of this type. Assuming that the nuclease activity has a role in mRNA turnover, a highly differentiated cell such as the reticulocyte which has lost its transcriptional machinery might be expected to have no such activity.

In several previous studies, the β-elimination reaction was used to remove m^7G from capped mRNA in order to test its influence on translation *in vitro*. The destabilising effect of unblocking (Figs 1, 2*c*) was then unknown, however. Shih *et al.*[3] compared the efficiency of translation of m^7G-capped and β-eliminated brome mosaic virus RNA and demonstrated that the positive effect of m^7G cap on translation in wheat germ extract was more pronounced at low RNA concentrations ($<20\ \mu g\ ml^{-1}$) than at high levels ($100\ \mu g\ ml^{-1}$) of RNA. The difference in the translational efficiencies might be due to degradation of some of the β-eliminated RNA by wheat germ exonuclease activity. Smith *et al.* and Baglioni *et al.* recently found that the extent of dependence on m^7G for mRNA translation varies with the concentration of potassium ions in protein synthesising reaction mixtures (personal communications). Therefore, in order to understand better the role of the cap structure in the translation of various RNAs, future experiments should be designed to take into account cellular exonuclease(s) and other factors that affect translation in cell extracts.

Polio, encephalomyocarditis (EMC) and satellite tobacco necrosis virus (STNV) RNAs do not contain 5′-cap structures[1]. These RNAs, however, are sufficiently stable to be translated in various model systems and also function as viral messengers in infected cells. How are these uncapped mRNAs stabilised? Allende *et al.*[10] reported that purified ribosomal RNA and 5S RNA are rapidly degraded when microinjected into *Xenopus* oocytes, but globin and *D. discoideum* mRNAs, RNA in ribosomes, and *Escherichia coli* suppressor 3 $tRNA^{tyr}$, which cannot be aminoacylated in oocytes, are all stable. These observations can be explained if extensive and specific secondary structures or the association of proteins, as observed for tRNA, and ribosomes, respectively, prevent 5′-cleavage by exonuclease activity. In this regard, it was found recently that polio virion RNA, the first viral messenger in polio-infected cells, has a viral protein covalently linked at the 5′-end[18]. Poliovirus RNA, EMC virus RNA, polio polysomal RNA, STNV RNA and possibly other messenger RNAs that lack a 5′-5′-inverted structure at the 5′-end may be protected against exonuclease attack by covalent or non-covalent interaction with protein(s) or by 5′-terminal secondary structure. In conclusion, the presence of a blocked or capped 5′-end results in protection of RNA against 5′-exonucleolytic degradation. In some RNAs, for example avian sarcoma virus (ASV) genome RNA which is capped[19] but translated poorly *in vitro*[20], caps may function mainly to confer stability rather than, as with reovirus mRNA, to promote translation. In support of this suggestion, the cap on ASV 35S RNA is not protected against RNase T1 digestion by mouse ascites 40S ribosomal subunits (M. Kozak, unpublished).

We thank M. Kozak for discussions, M. Morgan for technical assistance, and L. Burzio for initially demonstrating the microinjection technique.

Radio counterpart of the X-ray source 3U0901−09

A RECENTLY published position[1] of the X-ray source 3U0901−09 obtained from the Ariel V experiment overlaps the extent of the Abell cluster A754. Previous radio continuum observations of this area[2] revealed a complicated radio emission distribution. We are mapping a sample of Abell clusters and have made a map of the area containing A754. We find that the position ellipse of the X-ray source is in good agreement with a radio source complex with a very steep spectrum.

The observations were made at 2,695 MHz from the secondary focus of the 100-m radiotelescope of the Max-Planck-Institut für Radioastronomie. The beamwidth at this frequency is

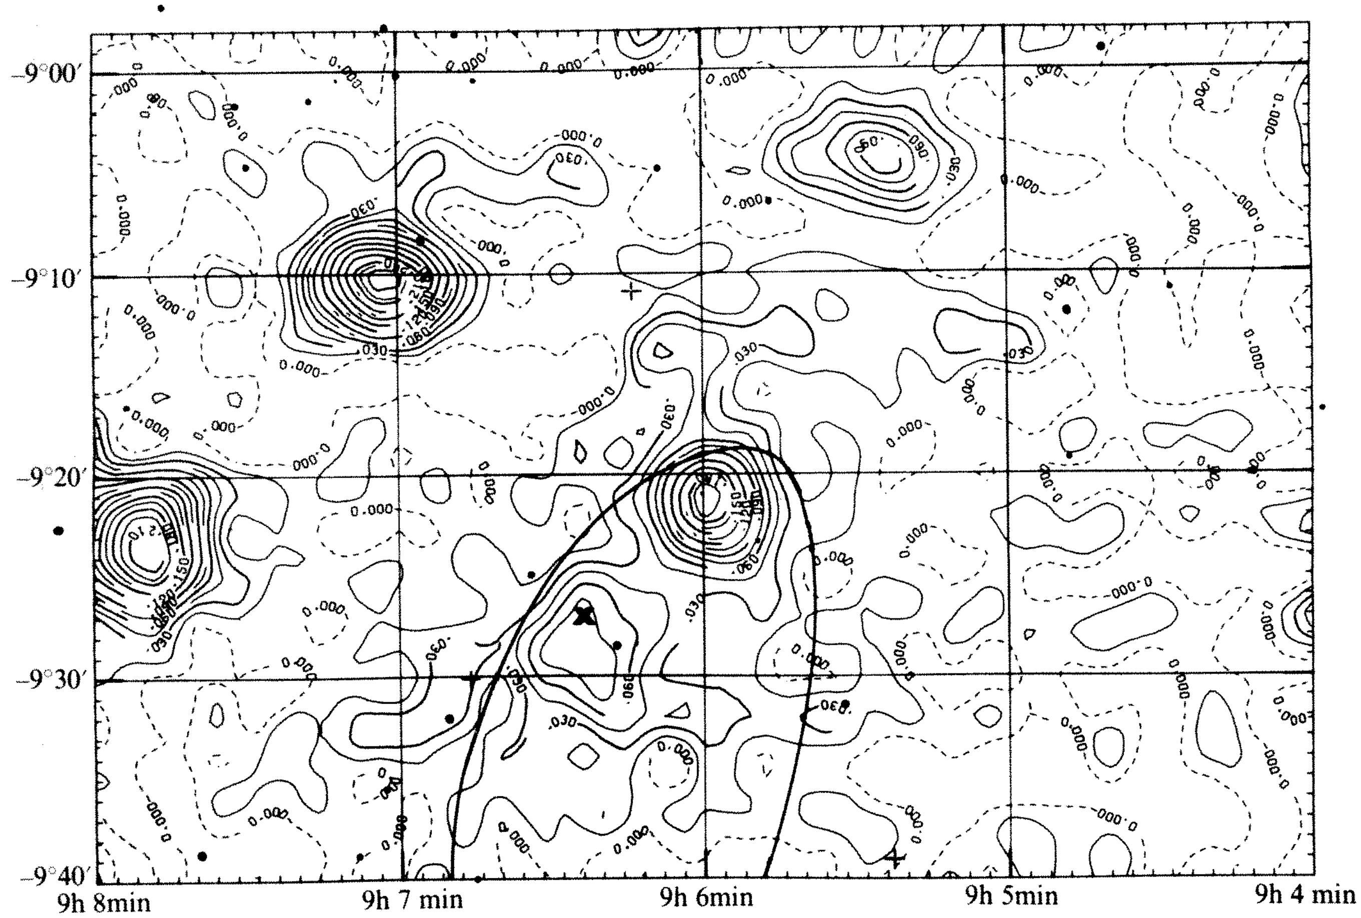

Fig. 1 The 11.1-cm map at an area near A754. Contours are in steps of 15 mJy per beam. Dashed contour shows the zero level. X, centre of A754. The position ellipse of the Ariel V measurement is also shown. Note 1 Jy per beam = 1.5 KT_a = 2.0 KT_{mb}.

4′.4 to 3 dB points. The receiving system is a dual channel correlation radiometer. In this receiving mode a single circular polarisation is combined with the signal from a liquid nitrogen termination in a hybrid, amplified in two phase-stable uncooled parametric amplifiers and correlated at intermediate frequency. The output signal is the difference in power between one circular polarisation and the cold load. The system noise temperature is about 100 K. The bandwidth over which excellent phase stability and tolerable low level of interference are possible is 100 MHz. With this receiver performance fluctuations of 14 mK r.m.s. s^{-1} are expected. In fact, some degradation of performance due to low-level interference and atmospheric fluctuations takes place, requiring an integration of 10 s to achieve 5 mK r.m.s. noise.

Observations were made on 25 April 1976. Scanning of the 42′ × 60′ area was in right ascension at 60′ min^{-1}. Scans were made at intervals of 1′ in declination, requiring 43 steps for the whole map. Two coverages were made and the intensity arrays added to give the map (Fig. 1). Calibration used the source 3C 286 ($S_{11.1}$ = 10.3 Jy) and an internal switched noise diode.

Figure 1 shows four sources, three of which are unresolved by our beam. Extended emission is seen within the position ellipse given for 3U0901 −09 by the Ariel V sky survey instrument[1]. The position ellipse also contains the centre of the Abell cluster A754. Previous observations of A754 were reported by Owen[2] at 1,420 MHz with the 300-ft NRAO radiotelescope. Since his beamwidth was 10′ only one extended source was found at 1,420 MHz in a position which agrees with the centre of gravity of the point source seen at 11 cm in the uppermost end of the position ellipse and the extended source coincident with A754. We have determined the flux of all sources at 11 cm wavelength and have collected our flux values together with Owen's values in Table 1. Our errors in flux determination were estimated to be ±10%. We estimate the error in the 1,420 MHz flux to be ±20% for the point sources and ±30% for the extended one. The spectral index of the two point sources (Nos 3 and 4 in Table 1) is in the range typical for nonthermal radio sources. The spectral index α ($S \propto \nu^{-\alpha}$) of 2.5±0.8 found for the complex which includes the flux of the sources 2a and 2b makes this source similar to other X-ray radio sources or sources in galaxy cluster[3,4,5]. The total flux of the whole complex may be higher than that given in Table 1 due to further emission outside the contours within which we integrate, but it should correspond to the flux which was determined, but it should correspond to the flux which was determined by Owen at 1,420 MHz. In view of this unusually steep spectrum we propose that the X-ray emission comes from this extended radio complex. We have no knowledge of the temporal variations of this source, which may be one of the reasons for this steep spectral index, and we suggest that observations at a number of frequencies should be made over a period of time to finally delineate the spectral index.

Table 1 Flux of sources at 11 am wavelength, and spectral index, α

Spectroscopic evidence for interstellar grain clumps in meteoritic inclusions

THE occurrence of a primitive, presolar grain component in carbonaceous chondrites has been indicated by several independent lines of evidence, including the discovery of isotopic abundance anomalies[1,2]. The occurrence of organic molecules, including amino acids, in these meteorites is also known[3,4], but their connection with a genuinely pre-solar grain component has been conjectural. We show here that an extract of organic material from the Murchison carbonaceous chondrite has an ultraviolet spectrum with an absorption band centred at $\lambda \approx$ 2,200 Å. The similarity of this feature with the well-known interstellar absorption band at the same wavelength, gives strong credence to an interstellar grain component within this meteorite.

Carbonaceous chondrites contain a significant mass fraction of organic compounds, mainly in the form of aromatic polymers. Typically about 30% of this material is of relatively low molecular weight and could be extracted by using hexafluoroisopropanol as a solvent. The remaining 70% is of higher molecular weight and is usually insoluble[3].

A sample of the Murchison chondrite (supplied by Dr. Onuma) was used to obtain an organic molecule extract with hexafluoroisopropanol. The absorption spectrum of this extract (Fig. 1) shows a conspicuous absorption hump centred at $\lambda \approx$ 2,200 Å, having a half-width $\approx$300 Å and bearing a remarkably strong similarity to the well-known interstellar extinction feature[6–8]. A band of this type is a property of a wide class of organic molecules having conjugated double bonds, for example, $C=C-C=C$, $C\equiv C-C\equiv C$, $C=C-C=O$, with a typical cross-section of $\sim 4 \times 10^{-17}$ cm^2 (refs 9, 10).

Although the 2,200-Å absorption band in the interstellar extinction curve has usually been attributed to graphite particles[11–13], this explanation is unsatisfactory. Spherical or nearly spherical graphite particles of radii $\sim$ 150 Å are required to reproduce the observed features of the astronomical band[14]. Non-spherical particles, or spherical particles with much larger radii will shift the band centre away from λ 2,200 Å, or distort the symmetry of the band. An origin of the interstellar λ 2,200 Å feaure in terms of complex organic molecules lodged in grain clumps would have an advantage in that the mean absorption profile (arising from electronic transitions in an ensemble of molecules) has a central wavelength and width which are independent of the shapes and sizes of the host grain clumps. On the basis of this interpretation, the astronomical and meteoritic spectral data would provide further supporting evidence for a connection between pre-solar interstellar material and inclusions in carbonaceous chondrites.

Fig. 1 The absorption curve of organic material in the Murchison carbonaceous chondrite extracted using hexafluoroisopropanol as a solvent.

Prebiotic molecules and interstellar grain clumps

INTERSTELLAR molecules detected by radioastronomical techniques in clouds such as OMC 1 and 2 in the Orion Nebula and Sgr B2 in the galactic centre span a wide range of types and complexity. Among the heaviest of the molecules recently discovered is cyanodiacetylene[1] ($H-C\equiv C-C\equiv C-C\equiv N$). There have been earlier detections of precursors to the simplest known amino acid glycine (formic acid and methanimine), and probable detections of polyoxymethylene polymers and copolymers[2–5] in interstellar clouds. We discuss here a possible identification of organic molecules of even greater complexity, and its implications for the start of biological activity.

Large departures from thermodynamic equilibrium in the interstellar medium and the co-existence of solid grains, molecules, radicals, ions and ultraviolet photons provide conditions which are ideal for the assembly of 'exotic' molecular species. If clumping of 100 Å-sized dust grains occurred by a process which we have discussed[6], highly complex organic molecules could be formed and become securely trapped during the 'welding' process of smaller grains. Such grain clumps could be widely dispersed amongst the particulate material in the Galaxy, being responsible for most of extinction and polarisation of starlight.

The spectral identification of highly complex organic species in the interstellar medium might seem hopeless. A property common to a wide class of such molecules, however, is an absorption band centred at $\lambda \simeq 2{,}200$ Å with a half-width ~ 250 Å, which arises mainly due to $\pi \to \pi^*$ or $n \to \pi^*$ electronic transitions in conjugated multiple bonds such as:

$$\begin{array}{ll} C=C-C=C & C=C-C=O \\ C=C-C\equiv C & C=C-C=N \\ C\equiv C-C\equiv C & C=C-C\equiv N. \end{array}$$

The absorption occurs due to transitions between electrons in n and π-orbital states to antibonding π^* states[7,8]. Specific examples of such transitions and relevant spectroscopic data have been cited elsewhere[9]. In general, this absorption band occurs in most highly complex organic species, with a typical value of ~ 200–300 Å for the half-width, and with a molar extinction coefficient $\varepsilon \simeq 10^4$ cm^{-1} (g mol l^{-1})$^{-1}$ (refs 7, 9), which implies an absorption cross-section of $\sim 4 \times 10^{-17}$ cm^2. A typical case is the curve for mesityl oxide (Fig. 1).

It is tempting to identify this feature with the well-known 2,200-Å band of the interstellar extinction curve. The smeared-out mass density ρ of molecules with molecular weight M required to produce the observed extinction coefficient at 2,200 Å of $\sim$ 1.5 mag kpc^{-1} (refs 10, 11) in the interstellar medium is

$$\rho \simeq 2 \times 10^{-27}(M/100)\,\mathrm{g\ cm^{-3}}.$$

For $M \sim 100$ we obtain a value of ρ which is $\sim 10\%$ of the total available CNO density in the interstellar medium. If this material is assumed to be homogeneously mixed with silicate-type grains of radius a, the condition for optical depth less than unity within a single grain at the band centre is

$$a < \sim 3 \times 10^{-5}\ \mathrm{cm}.$$

It may not be fortuitous that this upper limit is about twice the 'typical radius' required for interstellar silicate grains.

Several amino acids of biological importance have been discovered in carbonaceous chondrites[12] and there has also been an identification which is strongly suggestive of the existence of polyoxymethylene polymers or copolymers in the Allende carbonaceous chondrite[13]. Such polymers could have served as glueing agents for smaller grains in prestellar molecular clouds. It is also of interest that an extract of organic materials from the Murchison chondrite using hexafluoroisopropanol as a solvent showed a 2,200 Å absorption feature, typical of conjugated double bonds of the type considered above, and similar to the interstellar extinction hump at this wavelength[11].

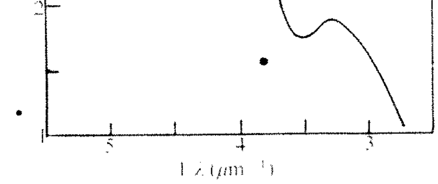

Fig. 1 Molar extinction coefficient ε (cm^{-1} (g mol l^{-1})$^{-1}$) of mesityl oxide

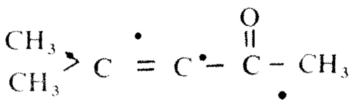

$$\begin{matrix}CH_3 \\ CH_3\end{matrix}\!\!>C=C-\overset{\overset{\displaystyle O}{\|}}{C}-CH_3$$

as a function of inverse wavelength[8].

We tentatively conclude that these data could be interpreted as independent new chemical evidence of the existence of composite grain clumps in the interstellar medium and in carbonaceous chondrites. Moreover, such grain clumps probably include a significant mass fraction of highly complex organic, prebiotic molecules which could have led to the start and dispersal of biological activity on the Earth and elsewhere in the Galaxy.

Even if all the CNO elements on the Earth's surface were initially in the form of the biologically important 20 amino acids, their linkage into feasible peptide chains could not have occurred by chance. Some process of natural selection is required, and this is usually held to have occurred under terrestial conditions. If interstellar grain assembly occurred in prestellar molecular clouds already containing these amino acids, pre-Darwinian selection leading to the production of self-replicable peptide chains, could have depended upon the sticking properties of the various molecules on to the polymeric coatings on 100 Å-sized grains. A welded composite grain with a 'cellular' structure on the scale of $2\pi \times 100$ Å could have served as the host system for the earliest primitive gene in a manner similar to that discussed by Cairns-Smith[15].

We now consider the selective mechanisms which could have operated in the growth and evolution of grain clumps, and their possible bearing on the development of a primitive biological system. Not all polymer coatings have the same sticking probabilities α (ref. 6). Some combinations are more probable than others. Suppose $\bar{\alpha}$ denotes the average sticking probability. What would be the optimum situation for clump growth? A reproducible situation with sticking probability only slightly above $\bar{\alpha}$ would be better than a non-reproducible situation with probability much greater than $\bar{\alpha}$. This is because the latter system, if it occurred, would soon be covered up by further growth of clumps. Once the possibility of a reproducible system is admitted, what reproducible system, among possibly many such systems, would become most widespread? The answer to this question is: a system which also promoted clump division. This leads not only to more clumps but also to a greater total mass of clump material, because of the advantageous surface/volume ratio.

Lastly, we turn to the problem of protection of pre-biotic material against external disruptive agencies, for example, ultraviolet light. Whilst this protection could be provided by an outer shield of solid grains, such a system would be biologically inert. A clump stripped of its outer polymeric coating would not be suitable for sticking, even if it was able to preserve itself. A more refined protection system in the nature of a biological cell wall would be much better, since such an outer surface could permit organic molecules to stick, as well as to diffuse through it.

Thus there seem to be two somewhat different types of selective process which could be operative under interstellar conditions. First, a competition for clump growth in the absence of disruptive agencies, for example, within a pre-stellar cloud; and second, a competition for organic materials (or even for sticking) in a more hostile environment in the presence of disruptive agencies. With the development of a cell wall, the last step could presumably be to 'split out' the inorganic grains which started off the whole process.

Gravitational radiation detector observations in 1973 and 1974

MARYLAND–ARGONNE gravitational radiation detector observations for 1973–74 have recently been published[1]. This letter contains additional information about how the data were taken and analysed.

A primary goal was to eliminate any unconsciously applied human bias which could affect results. To this end, I removed myself from direct participation in the data reduction beginning in 1972. Mr Michael Lee developed programs for a magnetic tape and computer system of data analysis. A number of checks of the computing were set up. The first check was an independent, analogue experiment, in which data were recorded on pen-and-ink charts, with an on-line computer marking the charts whenever the Maryland and Argonne detectors both crossed threshold within 0.1 s. The pen-and-ink recorder experiment had two outputs, one with, and one without, a time delay introduced into one of the channels before the computer looked for simultaneous threshold crossings. Charts for the data with and without the time delay were marked in coded form (which changed from time to time). Mrs Alessandra Exposito searched the charts for statistically significant coincidences without knowing which charts were which. This analogue procedure found excess coincidences at zero time delay during the same periods that the computerised experiment found them.

In a second checking procedure, Mr William Davis inserted artificial pulses into the gravitational radiation detectors at certain times unknown to the programmer, Mr Michael Lee. Lee correctly identified times when artificial pulses were present and absent. Third, Mr Bruce Webster prepared copies of old data tapes, some identical with the originals and others with one or more channels replaced by the same detector data from another time period. Lee had no knowledge of the information recorded on the magnetic tapes. Lee's analysis correctly identified these tapes.

The telephone circuit from the Argonne detector to Maryland was suspect even though the data were transmitted in coded digital form. The recent paper includes all data for a period when there was no telephone circuit and clock-synchronised recorders were employed at the two detector sites. An excess of coincidences over accidentals was observed during that period.

A major effort has been made to eliminate computing errors. Maryland magnetic tape data were sent to several other research groups together with data on the computer programs and lists of coincidences, in return for raw data from their experiments. During the data exchange, errors were discovered in the Maryland programs and in the procedures of other groups. The Maryland errors were acknowledged quickly and carefully corrected. The differences have now been resolved, and independent groups have confirmed the details of the revised Maryland programming. At the request of two research groups, the data exchange was to be private until agreement could be reached on publication. It is regrettable that incorrect and premature reports on the data exchange have appeared in the literature.

Two of the four authors of ref. 1, Steppel and Lee, independently prepared computer programs to process these data. In summary, results of the magnetic tape computer experiment, the pen-and-ink recorder experiment, and the data exchange indicate that for certain periods there is an excess of coincidences over accidental ones, with significance as great as 5.6 s.d. The use of several independent programs and of the checks in which the searcher did not know what was on the tapes or charts indicates that human observer bias and programming errors have been successfully removed.

This research was supported in part by the National Science Foundation and in part by the Computer Science Center, University of Maryland.

Radiometric measurement of stratospheric HCl

INTEREST in the effects on atmospheric ozone of man-made chlorine compounds has prompted research into their stratospheric chemistry. As HCl is expected to be the major temporary sink for free chlorine in the stratosphere[1–4], measurements of its vertical mixing ratio profile could yield useful information as to the major source of chlorine and its future effects on ozone concentrations. We have used a balloon-borne pressure modulator radiometer (PMR) to measure the atmospheric absorption of solar infrared radiation at sunset, and we report here a vertical mixing ratio profile for gaseous HCl for the altitude range 16–39 km.

The major feature of the PMR is a cell containing gas (HCl, in this case) through which the incoming radiation passes[5]. The gas pressure is modulated at about 19 Hz and the mean pressure in the cell chosen to give maximum modulation of cell transmission at HCl spectral line centres. Thus the incoming radiation is selectively modulated in those narrow spectral regions where atmospheric HCl absorbs, and so the pressure modulator cell acts as a filter of very high resolution ($\sim 4\times10^{-3}$ cm^{-1}).

The front optics of the radiometer is a servocontrolled Sun tracking system built by Denver University[6], which maintains an image of the Sun at the detector. The optical system also contains a rotating chopper which modulates the incoming radiation at 400 Hz and an optical filter which defines a pass band about 300 cm^{-1} wide around 2850 cm^{-1}. This region of the spectrum contains most of the fundamental vibration–rotation band of HCl. The detector, made of lead selenide at ambient temperature, receives radiation which has components at 400 Hz (the wide-band signal), at 19 Hz (the PMR signal) and at 400 ± 19 Hz (the side-band signal). The PMR and side-band signals contain the same information but the latter is used for instrumental convenience. The side-band:wide-band ratio is related to the amount of atmospheric HCl in the path between the instrument and the Sun.

The results presented here were obtained on a flight from Holloman USAF base, New Mexico (32° 52′N, 106° 07′W) on 17 March 1976. The radiometer remained at its float altitude of about 35.5 km until after sunset and was able to take measurements for solar zenith angles ≥90°. In this way the Sun is viewed through a long atmospheric path, enabling low concentrations of trace constituents to be detected. This technique (limb scanning) also allows vertical resolution in mixing ratio profile to be obtained. Signals for zenith angles <90° are used to calculate the level of the level of the side-band:wide-band ratio when there is no atmospheric absorption.

The mixing ratio profile has been derived from the data using a computer model which calculates the signals expected from a PMR for a given atmosphere by performing a line by line numerical integration across a Voigt profile for all the HCl spectral lines in the pass band of the filter. The spectral line strengths and Lorentz halfwidths used are those given by Toth *et al.*[7,8]. The results are shown in Fig. 1. Relative errors are indicated; also, at the present stage of analysis, there may be an absolute error of up to ±20% in the

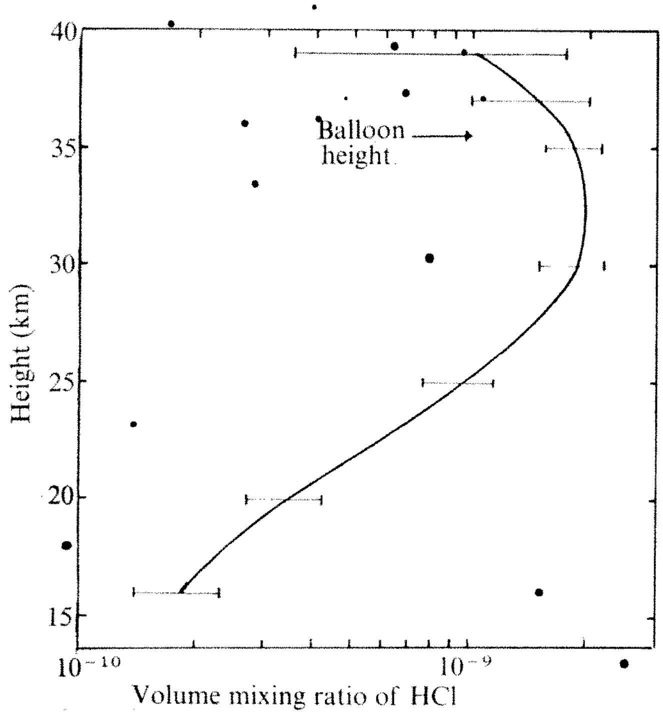

Fig. 1 Vertical profile of the mixing ratio of HCl in the stratosphere calculated from measurements of atmospheric transmission.

mixing ratio. The retrieval takes account of atmospheric temperature structure (measured by radiosondes coincident with the flight) and of the effects of atmospheric refraction. Small corrections have also been made for the estimated effects on the wide-band and side-band signals of other atmospheric constituents which absorb in this spectral region, using the spectral line data tabulated by McClatchey *et al.*[9].

The shape of the mixing ratio profile implies that the major source of HCl in the stratosphere is around 32 km. Other measurements of HCl (refs 10–13) have been based on the measured absorption of individual HCl spectral lines, whereas the PMR uses all the lines in the band. Figure 2 shows that the mixing ratio profile given here is similar to those of Ackerman *et al.*[11] and Williams *et al.*[12] but that its shape is different from the most recent profile measured by Raper *et al.*[13].

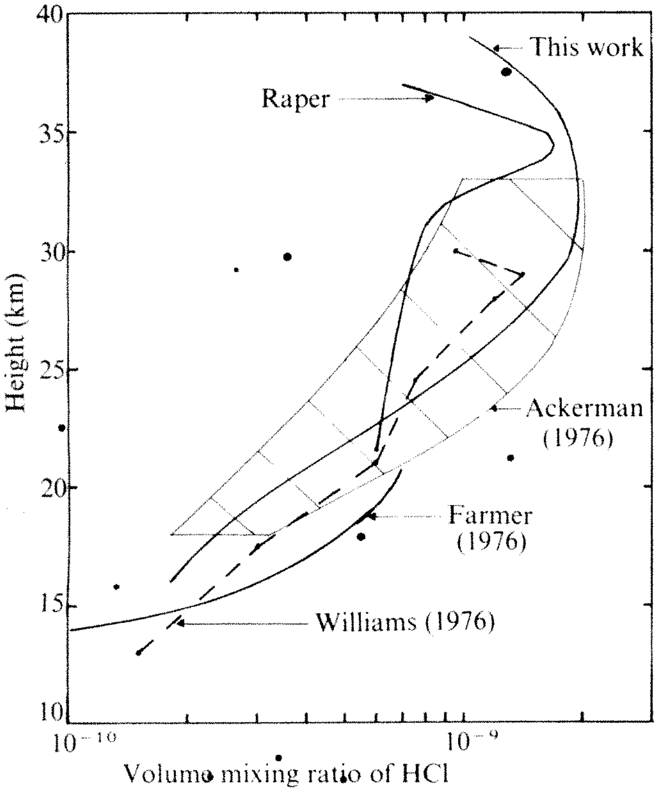

Fig. 2 Mixing ratio profiles of stratospheric HCl. A comparison of the results of this work with other measurements.

Mantle helium in the Red Sea brines

HELIUM isotope studies on terrestrial samples have revealed the existence of two helium components which are clearly distinct from atmospheric helium. The first of these, which we term 'crustal helium', was identified in 1946 in natural gas wells[1]. This crustal component is produced by radioactive decay of U and Th to ^{4}He, with ^{3}He production by (n, α) reactions on Li; the resulting helium is characterised by $^3\text{He}/^4\text{He} \simeq 10^{-7}$, one-tenth of the atmospheric ratio[2]. The second component, 'mantle helium', was discovered as 'excess ^{3}He' in deep ocean water, attributed to a flux of primordial helium from the mantle[3]. Studies of the $^3\text{He}/^4\text{He}$ ratio in deep water on the East Pacific Rise[4] and in helium trapped in submarine basalt glasses[5,6] have shown that this mantle component is characterised by $^3\text{He}/^4\text{He} \simeq 10^{-5}$, about 10 times the atmospheric ratio and 100 times the ratio in crustal helium. Basalt glasses from the Western Pacific Lau Basin, the East Pacific Rise, and the Mid-Atlantic Ridge contain trapped helium with similar $^3\text{He}/^4\text{He}$ ratios, indicating that mantle helium in at least three areas in which new lithosphere is being formed has a unique and uniform isotopic signature.

The hot brines in the axial rift of the Red Sea[7] provide an opportunity to sample helium at another plate margin, and to determine the extent to which these brines have interacted with mantle-derived material. Isotopic and chemical studies of the brine water[8,9] have shown that the source water for these geothermal brines is ocean water of normal salinity which circulates downward through evaporites and horizontally along fissures in the axial basalts to reach the brine-filled depressions. We now report measurements of helium and neon which reveal additional information on the origin of these brines and their relationship to the Red Sea rift.

Our samples were collected on the 1966 Woods Hole CHAIN-61 expedition, using a Nansen-bottle 'piggyback sampler' which recovers samples isolated at *in situ* pressure in copper tubing[10]. We analysed two samples taken 2 m apart from the Atlantis II Deep (Station 714, 21°20.5′N, 38°04.5′E); the bottom bottle was 43 m above the bottom in the middle of a 56 °C, 126-m thick layer. From Discovery Deep we analysed three samples collected over a 7-m interval (Station 717, 21°16.7′N, 38°02′E); in this case, the bottom bottle was 42 m

Concentrations in brine samples are accurate to 7% except for values shown in parentheses which are accurate to ~ 15%. Values for surface seawater (28 °C, 38‰ salinity) are for solubility equilibrium with air at 1 atm (ref. 11). Helium isotope ratios are accurate to 5% and are reported relative to the ratio 1.40 × 10^{-6} for atmospheric helium[12]. Sample designations refer to cast and bottle number.

above the bottom in the 44 °C, 164-m thick layer. Conductivity measurements aboard ship showed that the salinity of each sample was the characteristic brine value of 257.5 g kg^{-1} (ref. 9). The samples, each about 20 cm^3, were sealed in the copper tubing with refrigeration clamps and stored at 4 °C until analysed. They were collected at the same locations as those analysed previously for N_2, Ar and total CO_2 (ref. 10).

Gases were extracted in a vacuum line made of Corning 1720 glass and stainless steel. In vacuum all samples were clear and colourless, indicating that no contact with oxygen had occurred[10]. The extraction and rare-gas purification procedure, which has been tested extensively on seawater samples, collects > 99.9% of the He and Ne. The total system and spectrometer blank (in cm^3 STP) is 9 × 10^{-15} for ^{3}He, 1.3 × 10^{-9} for ^{4}He, and 1 × 10^{-10} for Ne, < 0.1% of the sample in each case. ^{3}He, ^{4}He, and Ne were measured on a double-collecting mass spectrometer[5] which completely resolves ^{3}He from HD + H_3. A charcoal U-trap chilled at −195 °C was included in the static volume during analysis to reduce interference from Ar^{2+} at mass 20. The ^{3}He/^{4}He ratio was measured in double-collection mode, and the neon was then measured by voltage switching. Air standards were used to calibrate the helium isotope ratios and the absolute amounts of He and Ne as determined by peak height measurements.

The results, summarised in Table 1, show that both brines are highly enriched in helium with a mantle-helium isotopic signature. Because the large variations in salinity in the 15 known brine pools[13] are due to addition of salt from evaporites and dilution by mixing with seawater[9], concentrations of gases and their enrichments relative to solubility equilibrium with the atmosphere are best expressed in terms of gas to water ratios. The measured He concentrations (~ 10.5 × 10^{-6} cm^3 STP per g of brine) are thus given as He/H_2O ratios in Table 1 based on a salinity of 257.5 g kg^{-1}, and are compared with atmospheric-equilibrium solubility ratios in Red Sea surface water at 28 °C, 38‰ salinity, the source-water values estimated from stable isotope ratios[8] and dissolved Ar in Atlantis II brine[10]. On this basis the Atlantis II and Discovery brines are 380 times supersaturated in helium. The ^{3}He supersaturations are even more spectacular: a factor of 3,300, which can be compared to the highest ocean water enrichment factors of 1.5 observed in deep water adjacent to the East Pacific Rise[1]. In contrast to these large helium anomalies, the neon concentrations for both brines agree within errors with equilibrium values, indicating neon enrichments of < 10%.

The ^{3}He/^{4}He ratio in these brines, 1.2 × 10^{-5}, is similar to that in helium in the glassy rims of recent tholeiitic basalts on Atlantic and Pacific rises[5,6] (Fig. 1). Since helium in evaporites should be pure 'crustal' helium with a ratio ≃ 10^{-7}, we conclude that the helium in these brines is primordial helium extracted from basalts in the axial rift during subsurface flow of brine from evaporites to the brine depressions. Comparison with the enrichment factors in brines against original seawater for other elements[9] shows that ^{3}He ranks with the trace metals Pb, Mn, Fe and Zn, as the only elements exhibiting enrichments of a factor of > 1,000 in these brines; ^{4}He is next in order (enrichment ≃ 400), and all other species are enriched by factors < 100. Both the trace metal and major element enrichments are entirely consistent with derivation from evaporites, as shown by comparison of added salts in Red Sea and known

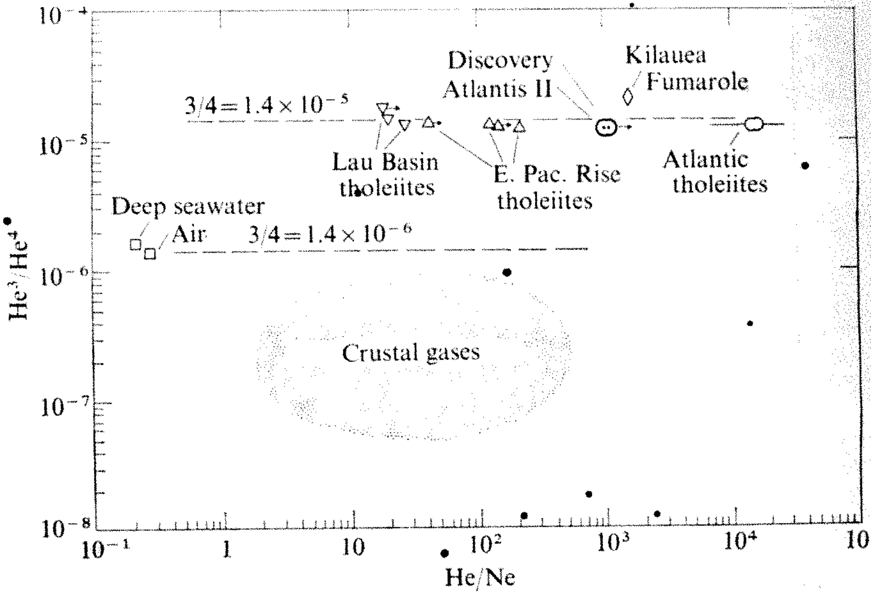

Fig. 1 ^{3}He/^{4}He against He/Ne ratios in Red Sea brines, tholeiitic basalts, Kilauea volcanic gas, and crustal gases. Arrows on points signify lower limits for He/Ne ratios.

salt-deposit brines[9]. In contrast, the similarity of helium isotope ratios in fresh basalt glasses and in the brines indicates that $> 80\%$ of the brine helium must have been extracted from basalts. Helium is thus the only component in these brines which has so far been shown to require a derivation from a source other than the Red Sea evaporites.

Comparison with helium concentrations in recent basalt glasses[5,6] indicates that the He/H_2O ratio in these brines is equivalent to a basalt/H_2O ratio of the order of 2–10 g per g for complete extraction. The slightly lower ^{3}He/^{4}He ratios in the brines than in the basalt glasses may be attributed to a 10–20% dilution with radiogenic helium produced in the evaporite deposits by decay of U and Th. Weiss[10] showed that the Ar/H_2O ratio in these brines is close to the original solubility ratio. As the ^{4}He/^{40}Ar ratio in fresh basalts is about 8 (refs 14, 15), $< 1\%$ of the argon in these brines has been derived from basalts.

Figure 1 shows the ^{3}He/^{4}He and He/Ne ratios for the two brine samples compared with the values for air, crustal gases[16], tholeiite basalt glasses and a gas sample from Kilauea volcano[6]. For the brines we have estimated the He/Ne ratio in the 'excess' component above atmospheric solubility by assuming that the neon excess is $< 1.4 \times 10^{-8}$ cm^3 STP per g H_2O for both brines, that is, 10% of the measured neon concentration. For the injected component in the Atlantis II and Discovery brines, this estimate yields a lower limit for the He/Ne ratio of ~ 1,000; this value, plotted in Fig. 1 shows that Red Sea basalts are more similar in He/Ne ratio to Atlantic than to the Pacific basalts so far analysed.

The relationships in Fig. 1 show that the ^{3}He/^{4}He ratio is essentially identical in samples from four plate margins and three oceans in which the He/Ne ratios vary by a factor of 1,000. These large He/Ne variations are due either to an intrinsic heterogeneity in mantle primordial gas concentrations or to a He–Ne separation process which does not fractionate helium isotopes significantly[6]. Helium from the Red Sea brines and other plate margin basalts is also distinct from Kilauea helium, which has a 3/4 ratio ~ 15 times atmospheric, an indication that Kilauea may be tapping a different part of the mantle, more enriched in ^{3}He.

That ^{3}He and ^{4}He are the only Red Sea brine components which can be shown unequivocally to be derived from hydrothermal circulation in basalts, rather than in evaporites, has interesting consequences for exploration of possible hydrothermal systems in ocean-ridge basalts[17]. The ~ 3,000-fold enrichment of ^{3}He in Red Sea brines relative to seawater shows that ^{3}He (and total helium) should be by far the most sensitive indicators of hydrothermal emanations from ocean-floor basalts. We are now using helium isotope measurements in conjunction with a deeply-towed sample collection system to map hydrothermal plumes in active spreading centres[18].

The continental crust northeast of Newfoundland and its ancestral relationship to the Charlie Fracture Zone

CONTINENTAL edges that are matched in pre-continental drift reconstructions have generally been defined by an isobath. When the isobath chosen is too shallow, isolated bathymetric highs within the 'oceanic' area are interpreted as continental fragments that may consequently be moved at will to fill any gaps in the reconstruction[1]. Orphan Knoll (which had a history of uplift, erosion and subsidence[2] and Flemish Cap[3] are two such fragments for which lateral movements across the northeast Newfoundland shelf have been invoked[4]. Detailed bathymetric, magnetic and gravity surveys[5,6] have confirmed that the entire intermediate depth area of the northeast Newfoundland Shelf inshore of Orphan Knoll and Flemish Cap is continental in nature thereby invalidating reconstructions which assume otherwise. I show here that the offshore extension of the Hermitage–Dover fault in Newfoundland provided the line of weakness along which the Charlie transform fault developed.

Arcuate zones of magnetic anomalies dominate eastern Newfoundland and the northern Grand Banks[7] (Fig. 1). In the south central Grand Banks, the magnetic highs correlate with basement highs (Fig. 2) from which pre-Devonian metasedimentary rocks[8] were recovered. Similar rocks on Avalon Peninsula overlie the Precambrian volcanics responsible for the onshore portion of the magnetic highs. These arcuate 'continental' magnetic zones extend into the intermediate depth (1000 m) area of the northeast Newfoundland Shelf (Figs 1 and 2), strongly suggesting that it is underlain by continental crust. In support of this, continental basement can be traced westward along the reflection profile indicated in Fig. 2, from continental Orphan Knoll to the eastern edge of a deep sedimentary basin[9]. A similar seismic reflector can be traced eastwards from land in an entirely continental sequence to the western edge of the same basin[9]. The only possible discontinuity in continental basement from seismic evidence, therefore, underlies the sedimentary basin. But, one of the bands of high magnetic field originating onshore in Precambrian volcanic rocks crosses the basin at the same location as the seismic reflection profile (Figs 1 and 2), thereby bridging the gap. Continuity of continental crust from Newfoundland out to Orphan Knoll is, therefore, corroborated.

The continental area of the northeast Newfoundland Shelf seaward of approximately the 300-m isobath has, however, subsided with respect to the Grand Banks[7]. Although its southern fractured margin is clearly marked by an east–west line of magnetic anomalies at 48 °N (Fig. 1), the overall line of dislocation is marked by a gravity high (Fig. 3). This is partially due to the localised sedimentary load on the lithosphere[11] but the magnitude of the gravity anomaly can only be explained if the subsided crust has increased in density or has been thinned as a result of margin tectonics (R. A. Folinsbee, personal communication). The inverse correlation between changes in the gravity and magnetic field, which is evident on a local scale over the basin that lies along the line of dislocation, results from the thicker sedimentary section giving an increased load and higher gravity while increasing the depth to basement and, therefore, reducing the magnetic field.

Although the magnetic pattern of Flemish Cap contrasts with that of the Grand Banks, continental basement can be traced between them except for a 40-km wide zone in Flemish Pass[3]. This distance is, therefore, the maximum possible extent of crustal fracturing or thinning east of the Grand Banks. An overwhelming majority of the area between Orphan Knoll, Flemish Cap and Newfoundland is, therefore, continental, and no major lateral

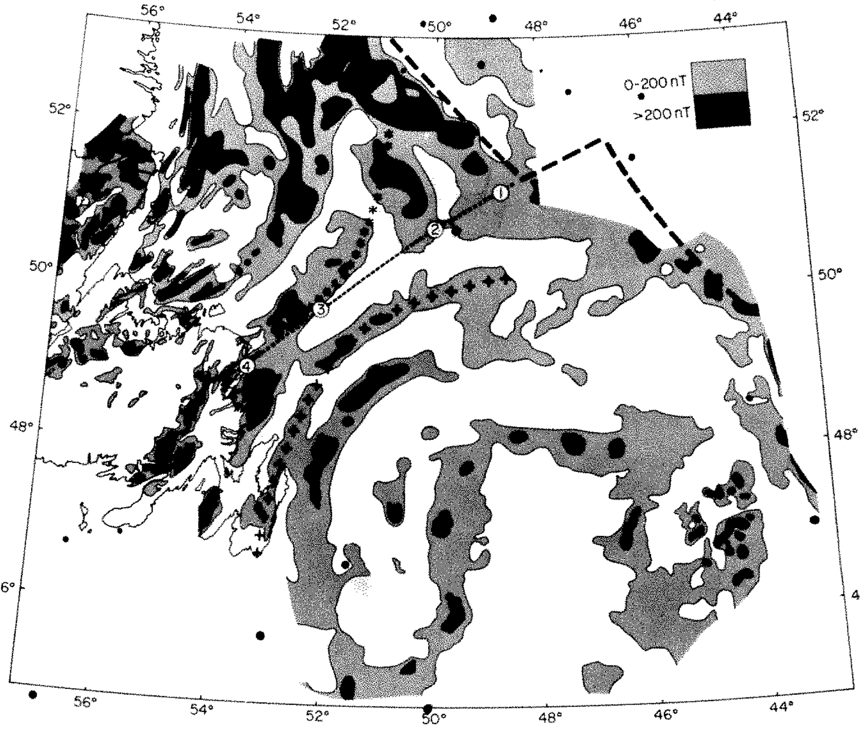

Fig. 1 The magnetic trends of the continental shelf northeast of Newfoundland based on tracks with maximum spacing of 10 km (refs 5,6). - - - -, Line marking 1 offset of edge anomalies, 2 termination of N.W.-trending anomaly pair, 3 divergence between offshore extension of Avalon and Gander (magnetic) trends, and 4 Dover Fault. ****, Localised magnetic trend obliquely crossing N.W.-trending anomaly pair. + + + +, Magnetic trend extending Precambrian volcanics beneath sedimentary basins crossed by Grant[9] seismic reflection line (see fig. 2). ––––, Ocean–continent boundary.

adjustment of the positions of Flemish Cap or Orphan Knoll has occurred. This requires that the continental edge used in palaeogeographic reconstruction should lie east of Orphan Knoll and Flemish Cap as indicated in Figs 1, 2 and 3.

An offset in oceanic magnetic lineations either side of the Charlie Fracture zone[10] correlates well with the northern edge of the subsided northeast Newfoundland shelf and with an offset of approximately 100-km in the gravity and magnetic 'edge anomalies' at the continental margin (point 1 in Fig. 1)[6-12]. This suggests that the Charlie transform fault can be related directly to an initial offset in the Canadian margin[10]. Attempts to identify the seaward extension of one of the faults in Notre-Dame Bay as the ancient line of weakness[13] controlling that transform fault[14,15] are only substantiated as far east as 52 °W (refs 9, 16), whereas the older and more fundamental crustal boundary represented in Newfoundland by the Hermitage–Dover Fault can be traced across the shelf to the inshore end of the Charlie Fracture Zone, by a series of disruptions in the geophysical data (points 1–4, Fig. 1).

A pair of positive and negative magnetic anomalies with a northwesterly trend, 100-km long and centred at approximately 51 1/2 °N, 50 1/2 °W, must overlie continental crust because they are superimposed by subsidiary N–NE trending anomalies that can be traced to pre-Mesozoic features ashore (Fig. 1). 'Basement' velocities of 5.1–5.3 km s^{-1} obtained over this region have been interpreted as indicating a decrease in the effect of the Acadian orogeny northeast of Newfoundland[17]. On the basis of correlation

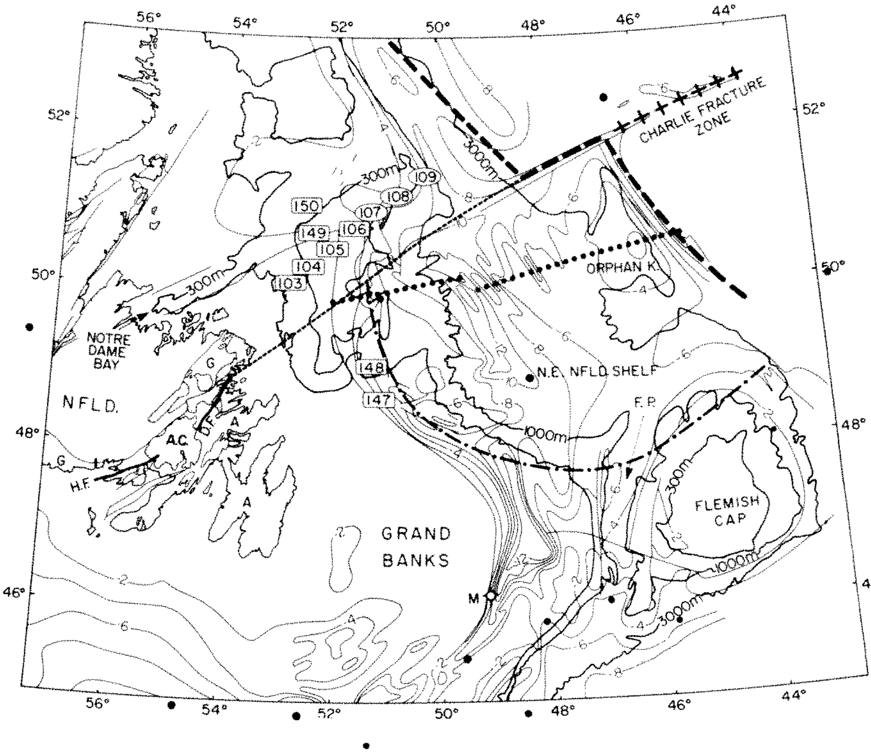

Fig. 2 Contours on basement (km) (refs 9,10) and bathymetry of the Newfoundland continental margin. – – – –, Ocean–continent boundary. –·–·–, Inshore edge of subsided crust beneath NE Newfoundland Shelf . . . ., Grant[9] seismic reflection line. A.C., Ackley City granite batholith; D.F., Dover Fault; H.F., Hermitage Fault; A., Avalon zone; G., Gander Zone; F.P., Flemish Pass. Numbered rectangles indicate location of refraction lines[17] with high basement velocity; numbered ellipses indicate low basement velocity.

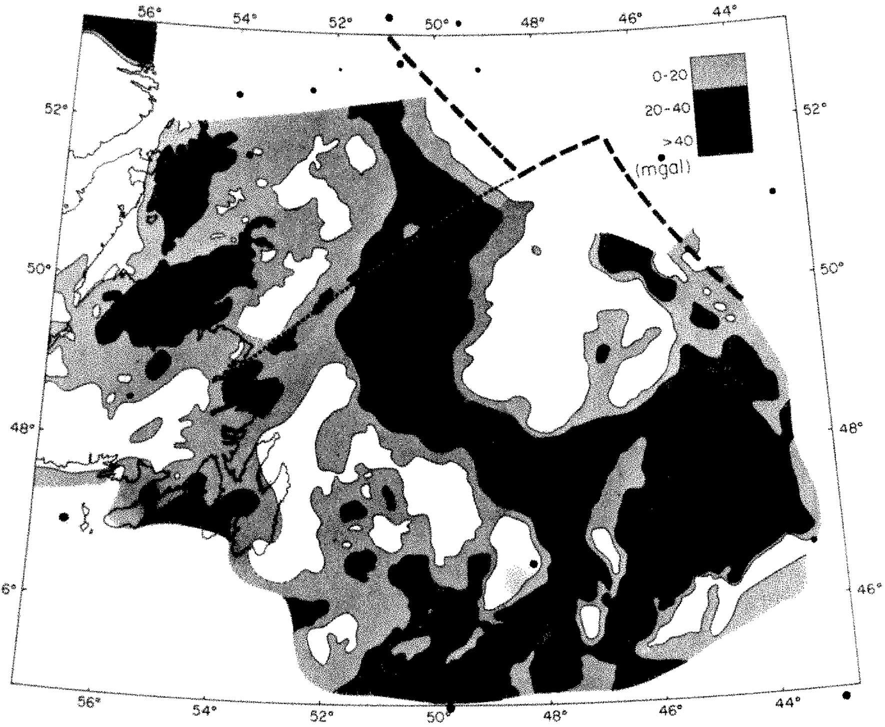

Fig. 3 The gravity trends of the continental shelf northeast of Newfoundland. Bouguer anomalies on land and free air anomalies at sea. Ocean–continent boundary and Dover–Charlie Fault Zone line from Fig. 1.

with magnetic field trends, however, the adjacent higher (Acadian?) velocities (5.7–6.3 km s^{-1}) probably extend to the continental margin north of the refraction lines. The lower velocity area has in fact subsided along faults subparallel to the continental margin as indicated by the change in depth to seismic basement (Fig. 2) and the increase in wavelength of the transverse magnetic anomalies. The northwest-trending anomalies, which reflect this basement faulting, are abruptly terminated along the southwestward projection of the trend of the Charlie Fracture Zone (2 in Fig. 1).

Further projection of this trend southwestward follows the boundary between the contrasting magnetic anomaly patterns of the Avalon and Gander tectono-stratigraphic zones[18]. The arcuate magnetic trends of the Avalon Zone and the Grand Banks veer steadily to the east while the trends of magnetic anomalies emanating from the Central Mobile Belt veer gradually northward (3 in Fig. 1).

The calculated depths to an intermediate crustal layer of velocity 6.9–7.6 km s^{-1} (ref. 17) can accomodate a 2-km normal fault[14] between refraction lines 148 and 149 (Fig. 2). The reduction in amplitude and increase in wavelength of magnetic anomalies that would be associated with such a fault, are found at the eastern edge of the high magnetic zone that enters Newfoundland on the western side of the Dover Fault (3 and 4 in Fig. 1).

The Dover[19] and Hermitage Faults[20] define the boundary between the Gander and Avalon Zones (Fig. 2). The fundamental nature of this boundary established on land, combined with the ability to trace its extension, by means of geophysical boundaries (1–4, Fig. 1), to an offset in the continental margin and the western end of the Charlie Fracture Zone, indicates that the Hermitage–Dover Fault Zone is ancestral to the Charlie Fracture Zone.

Cherkis[15,21] has suggested from magnetic field data that the line of weakness along which the Charlie transform fault developed is also the location of the Hercynian (Variscan) Front. Although magnetic trends in Europe have been interpreted as associated with Hercynian deformation[22], the seaward extension of any trend (magnetic or gravity) that might correlate with the Hercynian Front itself, is not apparent west of Ireland[23,24]. On most palaeogeographic reconstructions of the North Atlantic, however, those magnetic trends in Europe attributed to Hercynian deformation are roughly concentric with the arcuate magnetic zones of the Grand Banks and the Avalon Zone (Fig. 4). If the Hercynian Front lies at the northern limit of those magnetic zones, as in Europe, the implication would be that the Hercynian Front follows the Hermitage–Dover Fault Zone, but this suggestion can be opposed on geological grounds. Work in progress on clearer identification of those potential field trends associated with strictly Hercynian features in North America and Europe indicates that the arcuate zones in Newfoundland and Iberia are Precambrian rather than Palaeozoic. Hercynian trends would, therefore, be associated with disruption of the magnetic pattern rather than the pattern itself.

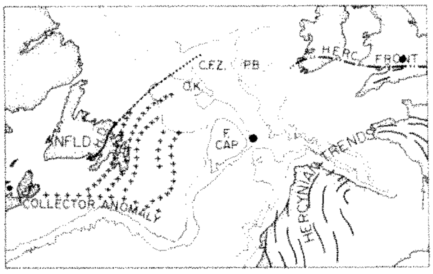

Fig. 4 Trans-Atlantic correlation between north-east Newfoundland and Hercynian trends. The Collector Anomaly[7] marks the southern limit of the Avalon arcuate magnetic zones. Juxtaposition of N. America and Europe is based on a morphological fit between the two margins in which no movement of continental fragments has been closed[25]. No other justification is claimed for this reconstruction, and the roughly concentric nature of trends prevails if other reconstructions are used. Preliminary palaeomagnetic results from Makapansgat and Swartkrans

THE South African hominid sites have proved difficult to date since radiometric and fission track methods have yielded no results, and faunal and geomorphological methods provide only wide limits. We describe here preliminary palaeomagnetic results which suggest that polarity stratigraphy can be used at these sites, and which indicate an age of between 2.8 and 3.3 Myr for Member 2 of the Makapansgat Formation.

Samples were collected at the Swartkrans and Makapansgat Limeworks sites. Both sites were described by Brain[1] who has subsequently revised his interpretation of Swartkrans[2] and in conjuction with Butzer has suggested new nomenclature[2,3]. Detailed mapping at Makapansgat by one of us (T.C.P.) has led to a revision of the stratigraphy which will be briefly described here. Full details will be published elsewhere.

The Makapansgat Formation constitutes the cave filling at the Makapansgat Limeworks hominid site, the cave being a solution cavity in the Malmani Dolomite of the Transvaal Supergroup. The lowest member (Member 1) is a contaminated travertine, locally bone-bearing, deposited on an irregular dolomite floor and locally tilted and distorted. Member 2, which forms the lower part of Brain's Lower Phase 1 unit[1], is a bone-bearing brownish-red well-bedded deposit of silt to fine sand grade material coarsening upwards, and is 2–10 m thick. It was deposited subaqueously within the cave and there seem to have been two depositories, one to the east and one to the west, separated by a floor high but controlled by a common water table level close to 1458-m elevation. Member 3, formerly the Grey Breccia of Lower Phase 1, is a thin (0.5–2.0 m) deposit consisting largely of a densely packed accumulation of bone cemented by calcite. Much of the Makapansgat fauna is derived from this Member which unconformably overlies Member 2. Member 4, formerly the Pink Breccia of Upper Phase 1, is a thick (3–15 m) deposit of pinkish silty sand material containing many angular chert and dolomite fragments, the larger of which are probably derived from roof falls, and local concentrations of bone. Member 5 (formerly the Red, or Phase II, Breccia) constitutes a locally well-stratified brownish-red silty sand matrix containing abundant chert and dolomite fragments and resting unconformably upon an eroded surface of Member 4. This unconformity probably represents a considerable lapse of time. Bone, often poorly preserved, is scattered throughout Member 5. Most of the remains of *Australopithecus africanus* were recovered from Member 3, but the posterior part of one cranium was recovered from Member 4, and one equivocal maxillary fragment from Member 5.

Forty palaeomagnetic samples were collected. The very varied physical nature of the rocks dictated a variety of collecting techniques. At Swartkrans 15 block samples, oriented magnetically, were collected. At Makapansgat 18 samples were cored and four (all from Member 1) were collected as blocks; all of these were oriented with a theodolite using Sun sights. Three samples from soft red muds (Member 2) in the deepest part of the cave were encased in small plastic cubes and oriented magnetically. Member 3 was not sampled, due to the poor mechanical properties of the rock at the accessible localities. All measurements were made in the Salisbury laboratory using a spinner magnetometer described by van Oorschot and Ridler[4]. Routine AF cleaning was used and a stable component was isolated at typical peak fields of about 20 mT; many samples showed evidence of rotational remanent magnetisation[5] at higher fields. Stable directions were arbitrarily classified as normal (N) or reversed (R) if they were within 40° of the relevant dipole field direction and as intermediate (I) if they fell outside this limit. Samples which showed erratic demagnetisation, or which exhibited internal disagreement between specimens were classified as giving no result (X).

The results for Swartkrans are shown in Table 1. One sample broke up during preparation and only 14 are shown in the table. Of these, eight are unstable or inconsistent, four are intermediate and two are normal. The large number of unstable samples is disappointing and the proportion of intermediate samples is higher than would be expected for a geomagnetic field effect. Even if the two normal samples represent an original primary magnetisation we do not feel that any chronological conclusions should be drawn from these data.

Table 1 Polarity data for Swartkrans

Unit	Sample No. (PM)	Polarity of samples
Member 1, Unit B1 Pink Breccia	1, 2	X, I
Member 1, Unit B2 Pink Breccia	3, 4	I, I
Member 1, Unit C Orange Breccia	5, 6, 7	X, X, X
Member 2, Inner Cave Stratified Brown Breccia	8, 9, 10, 11	I, X, X, X
Member 2, Outer Cave	13, 14, 15	N, X, N

Samples from Makapansgat showed much greater stability: the results are given in Table 2 and shown schematically in Fig. 1. Member 1 is entirely reversed. The beds at the point of sampling are tilted and when the palaeomagnetic directions are corrected for the tilting they become significantly more scattered (although still reversed), suggesting that the magnetisation was acquired after tilting. Member 2 is horizontally bedded and lies with minimum distortion upon the tilted Member 1, indicating that the deposition of Member 2 also occurred after the tilting. In Member 2 the lowest sample in the western depository is intermediate, whilst the remaining 5 horizons (containing 12 samples) are all normal. Low in Member 4 an intermediate horizon occurs, while high in Member 5 two reversed horizons occur followed closely upwards by two intermediate horizons.

The simplest interpretation of these results is that there is an upwards reversed to normal transition low in Member 2 which is otherwise entirely normal. An intermediate horizon low in Member 4 suggests a transition back to normal, but since Member 3 was not sampled it is not clear whether this is the transition immediately following that in

Table 2 Polarity data for Makapansgat

Unit	Sample No. (MT) by horizons	Polarity of horizon
Member 5	25	I
	24	I
	23	R
	18, 19	R
Member 4	20, 21, 22	I
Member 2, east	15, 16, 17	N
	12, 13, 14	N
Member 2, west	8, 9	N
	5, 6, 7	N
	10	N
	11	I
Member 1	2	R
	4	R
	3	R
	1	R

Member 2. A reversed section high in Member 5 followed by two intermediate samples suggests another reversed to normal transition. The placement of these polarity changes in the polarity time scale must depend upon other evidence for the approximate age of the beds.

Two other lines of evidence are available. The first is geomorphological. Partridge, using estimates of nickpoint migration and valley widening, calculates an approximate age for the cave opening at Makapansgat of 3.7 Myr (ref. 6). This is the time from which cave filling became possible, and is therefore a maximum age for the deposits. The second is faunal. Cooke[7] has used suid evidence to suggest that the Makapansgat fauna is "in the vicinity of 2.5 to 3.0 million years old" (quoted by Tobias[8] in a review of the evidence). White and Harris[9] have recently suggested that "the Makapansgat (suid) fauna is equivalent in age to Members B–C of the Shungura sequence" in Ethiopia. The palaeomagnetic stratigraphy of Shuey *et al.*[10] for the Shungura Formation places the base of Member B, the base of Member C and the top of Member C at about 2.9, 2.6 and 2.4 Myr, respectively. Vrba has used bovids to suggest tentatively that the Sterkfontein type site is "somewhere between 2 and 3 Myr" in age (personal communication) whilst Wells[11] feels that the Makapansgat fauna slightly predates that of Sterkfontein. The published faunal evidence is still rather scanty, but seems consistent with an age of between 2.5 and 3.0 Myr for Member 3, from which the bulk of the fauna derives. These figures therefore set an approximate younger limit for the age of Member 2 in which the polarity change occurs.

With these limits, the upwards transition from reversed to normal polarity low in Member 2 must have an age of 3.32, 2.94 or 2.80 Myr if we use Cox's[12] polarity time scale. The next closest Transitions in the same sense are at 3.90 Myr (Cochiti) and 2.13, 1.98 or 1.79 Myr (Réunion or Olduvai) using the same time scale, and are well outside the limits set by the geomorphological and faunal evidence. It must be emphasised that the palaeomagnetic argument depends heavily upon the limits provided by the other evidence, but if these limits are valid it becomes possible to state that Member 2 of the Makapansgat Formation lies within the Gauss normal epoch and has a maximum age of between 2.8 and 3.3 Myr. The assumed transition low in Member 4 could then be one of those higher up within the Gauss or at its upper boundary. The reversed and intermediate directions high in Member 5 occur after what is believed to be a considerable lapse of time and may be associated either with the Réunion or the Olduvai events.

All of these conclusions depend upon the cleaned palaeomagnetic directions being primary. Full details will be published elsewhere, but the demagnetisation behaviour both in direction and intensity suggests that a primary component has been isolated. Moreover, the mean directions of the normal samples in Member 2 both at sample and at horizon level lie closer to the dipole field than to the present-day field at Makapansgat, which suggests that recent remagnetisation has not occurred.

We thank Dr C. K. Brain and Professor P. V. Tobias for access to samples and for other assistance at Swartkrans and Makapansgat, respectively. Financial support was provided by the Wenner-Grenn Foundation for Anthropological Research and the University of Rhodesia.

New aspects of Middle Palaeolithic variability in western Europe

OBSERVATIONS are presented here on quantified aspects of Middle Palaeolithic variability which have not been studied systematically so far. The findings relate to differing degrees of secondary modification of lithic artefacts between assemblages. The variations correspond with distinct toolmaking entities defined for early Würm horizons in western Europe. They offer new perspectives, however, on the interpretation of Middle Palaeolithic inter-assemblage variability by suggesting the possible importance of non-cultural causes for some of this variability.

Distinctive Middle Palaeolithic assemblages are found within stratified sequences or between individual sites. These differences have been expressed quantitatively by comparing lithic assemblages through the classificatory method developed by Bordes *et al.*, particularly the polymodal frequency distribution of the racloir index, to which correspond characteristic tool type clusters[1]. Two main industry groups have been defined: le Moustier, which consists of the Denticulate, the Acheulian Tradition (or MTA) types A and B and the Typical Mousterian; and the Charentian, including the Ferrassie and Quina. This classificatory arrangement is the most widely accepted at present.

Controversy persists, however, regarding the significance of 'polytypic' Middle Palaeolithic phenomena. Resolution is theoretically important because of the increased knowledge which may be obtained on the behaviour of Neanderthal populations. Bordes interprets the different industry types as the manifestation of separate toolmaking traditions manufactured by distinct communities often coexisting within a same area[2]. Mellars supports the conclusion that most of the traditions are patterned chronologically[3], while Binford favours a functional interpretation: the different tool type clusters are specialised toolkits for the performance of various tasks by culturally similar populations[4].

The evidence discussed here is derived from some 120 assemblages excavated and sorted typologically by well-known workers over the last 25 yr. The method used concentrates on variable features of broad artefact groups and relies on the Bordes classificatory system. The basic observation unit includes all regularly retouched tools (or implements)—all racloirs types, denticulates and notches, bifaces and types nos 6–8, 30–35, 40–41 and 53–60 of the Bordes type list—whose frequencies are calculated against the number of implements plus all irregularly retouched, utilised or blank Levallois and non-Levallois flakes and blades. A distinction is therefore made between regularly transformed and utilised tools and flakes casually modified or utilised or without macroscopic wear traces. Sub-categories are defined, including (1) 'blanks and utilised flakes', nos 1–5 and 45–50, of the list; (2) non-Levallois unretouched flakes; (3) 'Levallois implements', or the number of pieces among Levallois flakes which are modified into implements; (4) racloirs and (5) denticulates and notches. Ratios of flake tools and blanks to cores per assemblages are also included.

Figure 1 shows the mean and range of implement frequencies for each Middle Palaeolithic industry type. The observed separation into two clusters agrees with a sorting of assemblages into le Moustier and Charentian groups. A maximum distance is found between the Denticulate and Charentian industries and the plotted ranges are discontinuous. The Typical and MTA show intermediary values overlapping with other industry types. A similar pattern was noted among individual sites sequences, for example, at Combe-Grenal, Hauteroche, Caminade, Armand Chadourne and le Maras, suggesting the presence of a recurrent, consistent trend.

Table 1*a* compares averages of frequency variations for artefact sub-categories among Middle Palaeolithic industries. The differential patterns are consistent with those shown for implement frequencies. Values for Levallois implements, though generally higher, conform with previously observed tendencies. In Table 1*b*, ratios of flakes and blanks to cores again conform with the earlier findings, the highest values being associated with the Charentian.

The data suggest that differential blank production and secondary modification are correlated. Higher blanks and flake implements to core ratios may be due to more exhaustive flaking of flint nodules, although other factors may be involved. Taken together, both could be attributed to non-cultural causes, for example, the influence of environmental circumstances inducing more economical uses of lithic material, as illustrated by the following studies.

In one case, it was shown that scarcity of flint in some crystalline regions determined increased secondary flaking and the development of primary flaking techniques making optimal use of available flints[5]. Another study has contrasted within the same le Moustier traditions, the open-air summer camps of short duration with the more sedentary rockshelters or caves settlements. In the latter, more Levallois blank pieces were secondarily transformed into implements than in the former.[6]

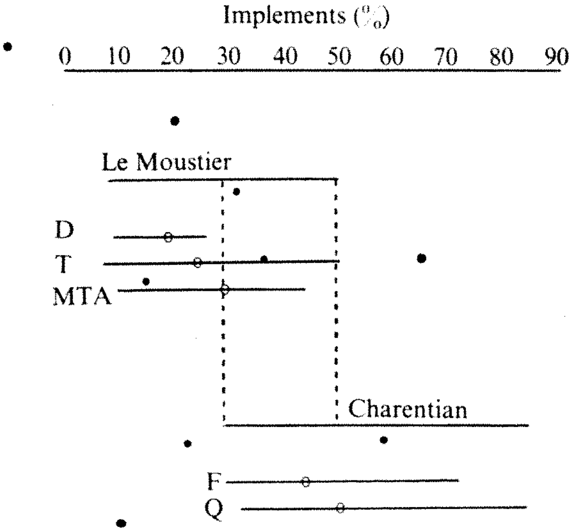

Fig. 1 Average implement frequencies and ranges for Middle Palaeolithic industries. D, Denticulate; F, Ferrassie; MTA, Moustérian de Tradition Acheuléene; Q, Quina; T, Typical; I, implement frequencies. Data are derived from artefact counts of sites in western Europe: Grainfollet (shelter, beach), Méru, Oissel, Houpeville (séries rousse et claire), Bihorel (III), Hamel (8), Busigny, Laigny (C), Evreux (6), Gros-Monts (2), Goderville (s. lustrée) Tillet (s. café-au-lait), Marcoing, Oldbury, Combe-Grenal (1, 6–38, 40–43, 46, 50–52, 54), Pech de l'Aze, locus I (3, 4F, A, B, C, 5, 6, 7), locus II (3, 4B, 4F, 4C2), Hauteroche (1, 3), Bouheben (1, 1′), Nantet I, Abri Chadourne (A, B, C, D), Caminade (1, 2, 3, 3s), la Rochette (7), Las Pénélos, Mas-Viel, Vauzelle, Plateau Baillard (1, 2), Chinchon, le Dau, l'Ermitage, Petit-Puymoyen (Grotte, 2, bréche, 3), Baume-Vallée, le Madriat, St. Maurice-sur-Loire, le Maras (1, 3, 4, 5), Ranc-Pointu, le Figuier, Blanzy, l'Hortus (16–21A, 18–25, 7–17), Rigabe (G), Bas-Guillotte, Grotte Tournal (1, 2, 4, 5), Abri Romani (4–8, 9–9a, 10–13), San Francesco, Kokkinopilos (Greece).

These explanations, though probably correct in their context, do not apply here for various reasons. First, most of the sites represented by the data are from regions where flint or equivalent raw materials are regularly available. Second, the most pronounced quantitative differences involve industries such as the Denticulate and the Charentian which occur mostly in rockshelter or cave sites in Western Europe, often within the same stratified successions. And third, more significantly, average differences in primary and secondary flaking co-vary with defined Middle Palaeolithic traditions, instead of forming non-cultural facies within them. These differences apply to Levallois and non-Levallois flakes. Consequently, the variations do not seem to be related to environmental circumstances such as a settlement dichotomy or regional scarcity of flint.

Table 1 Comparisons of *a*, major artefact class averages and *b*, ratios of flakes and flake tools to cores for each Middle Palaeolithic industry

	a				*b*
Middle Palaeolithic industries	Implements	Utilised and blanks	Levallois implements	Non-Levallois plain flakes	Flakes and flake tools ratios
D	17.1	24.7	35.0	57.7	20.2
T	22.7	26.5	36.4	50.8	22.5
MTA	25.6	25.4	49.4	48.5	14.7
F	43.0	21.4	49.6	35.4	31.0
Q	49.8	10.6	58.6	39.5	33.3
Sample averages	29.9	22.0	43.3	47.9	—
N assemblages	120	120	98	120	94

On the other hand, it would be difficult to test independently a hypothesis stating that these new observations constitute an additional set of cultural norms from distinct toolmaking traditions. Other quantitative data give little support for a 'cultural' hypothesis.

First, the implements frequency histogram for the entire sample is continuous and unimodal, suggesting a single phenomenon, whereas a polymodal model, analogous to that for the racloirs index, would be expected for distinct toolmaking norms. Second, the scatter diagram (Fig. 2) shows that high implement frequencies depend mostly on increased racloirs frequencies. Racloirs along with denticulates and notches are the most frequent Middle Palaeolithic implement classes. Their relative variations provide diagnostic criteria for the identification of most early Würm traditions in the Bordes system. Racloirs predominate strongly in the Charentian, denticulates and notches in the Denticulate and type B Acheulian Tradition Mousterian. We show above that the variations in implement frequencies revealed by this study are due to increases in racloirs manufacture rather than in miscellaneous implement forms. If preference for racloirs expresses the design norms of Charentian populations, it should be emphasised that the manufacture of stylistically alternative forms is never commensurate with that of racloirs in other toolmaking traditions. This analysis is the first to measure this non-equivalence or quantitative asymmetry. It confirms but amplifies the conclusion that racloirs constitute the most dynamic artefactual element in Middle Palaeolithic assemblages and also suggests that more than cultural preferences may be involved in high racloirs frequencies.

The discovery of new dimensions of variability adds to the number of open problems identified with the Middle Palaeolithic. These problems are present at a descriptive (statistical) and interpretative (anthropological) level: (1) to what extent do the graphic patterns for lithic assemblages represent either one or more original populations? (2) The issue of whether inter-assemblage differences can be interpreted in terms of the existence of distinct identity-conscious groups or of several discrete activities within a single one remains unresolved. Both interpretations are theoretically reasonable but neither has been subjected to sufficiently stringent tests.

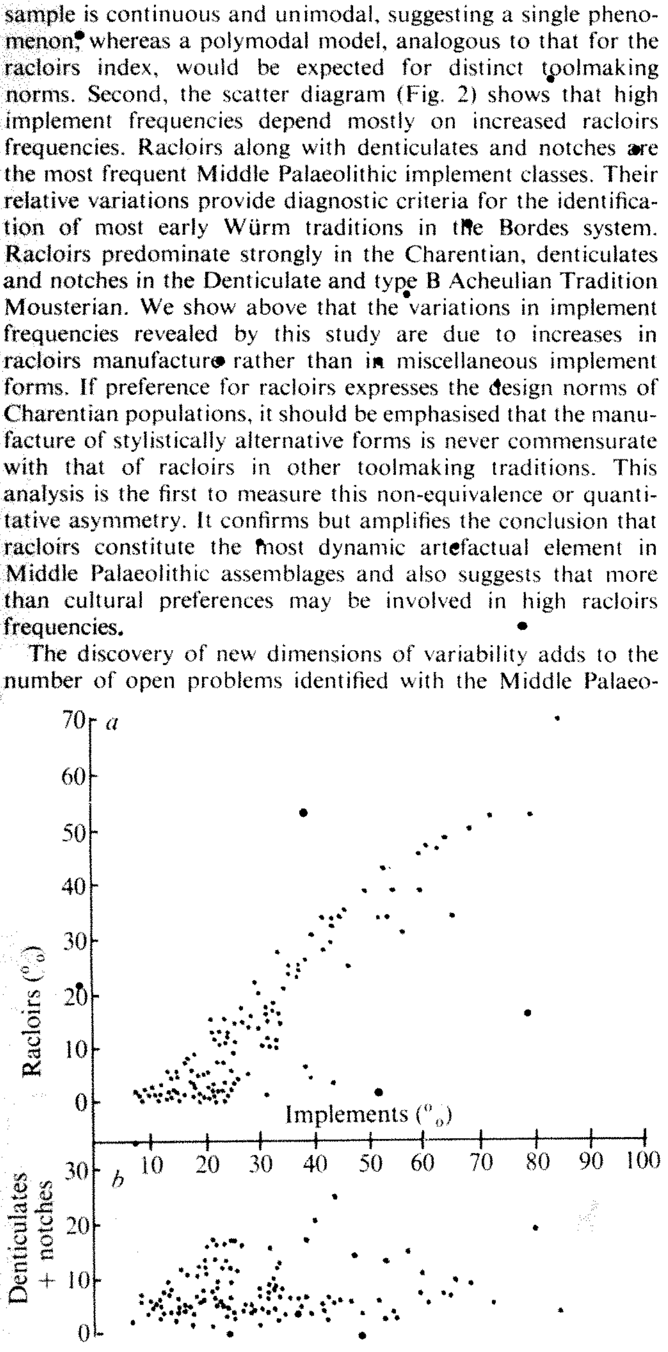

Fig. 2 Scatter diagram of implement frequencies (I) with *a* racloirs (R) frequencies and *b* denticulates and notches (D + N) frequencies. Only *a* shows positive association.

This research was supported by a Canada Council Doctoral Fellowship while at Cambridge University. We thank Dr C. B. M. McBurney for helpful advice, Professor F. Bordes and members of his laboratory, Professor H. de Lumley, Professor E. Bonifay and J. Guichard for their help.

'Modern' lizard from the Upper Triassic of China

LIZARDS are the most numerous, varied and widespread of living reptiles. An essentially modern lizard fauna has existed throughout the Tertiary and members of many modern lizard families are known from the late Cretaceous. Earlier in the Mesozoic, very few fossils of lizards are known. Lizards from the Upper Jurassic may be related to the ancestors of modern groups, but are placed in distinct families. Lizards previously described from the Upper Triassic of Europe[1] and North America[2] are considerably more primitive, retaining many cranial features in common with their ancestors from the Upper Permian and Lower Triassic[3]. We give here the first description of an Upper Triassic lizard with an essentially modern cranial morphology. This specimen is interesting with respect to the origin, differentiation and zoogeography of the modern lizard groups.

Class Reptilia
Order Squamata
Suborder Lacertilia
Infraorder Incertae Sedis
Family Fulengidae n.
Fulengia youngi, gen. nov. et. sp. nov.

Holotype: CUP 2037, skull, lower jaws and associated vertebra; collection of the Catholic University of Peking, now housed in the Field Museum of Natural History, Chicago. Collected by Fr E. Oehler, SVD in 1948 or 1949; part of a rich fauna of therapsids and archosaurs[4].

Locality and horizon: Ta Ti, Lufeng Basin, near K'un-ming, Yunnan Province, China. Dark Red Beds, Lower Lufeng series, Upper Triassic, equivalent to the Norian or Rhaetic of Europe[4]. The generic name is an anagram based on the locality from which the specimen was collected; the specific name honours the work in this region by Dr C. C. Young.

Diagnosis: a combination of the following characteristics distinguishes this form from other lizards previously described from the Mesozoic and Cainozoic: median

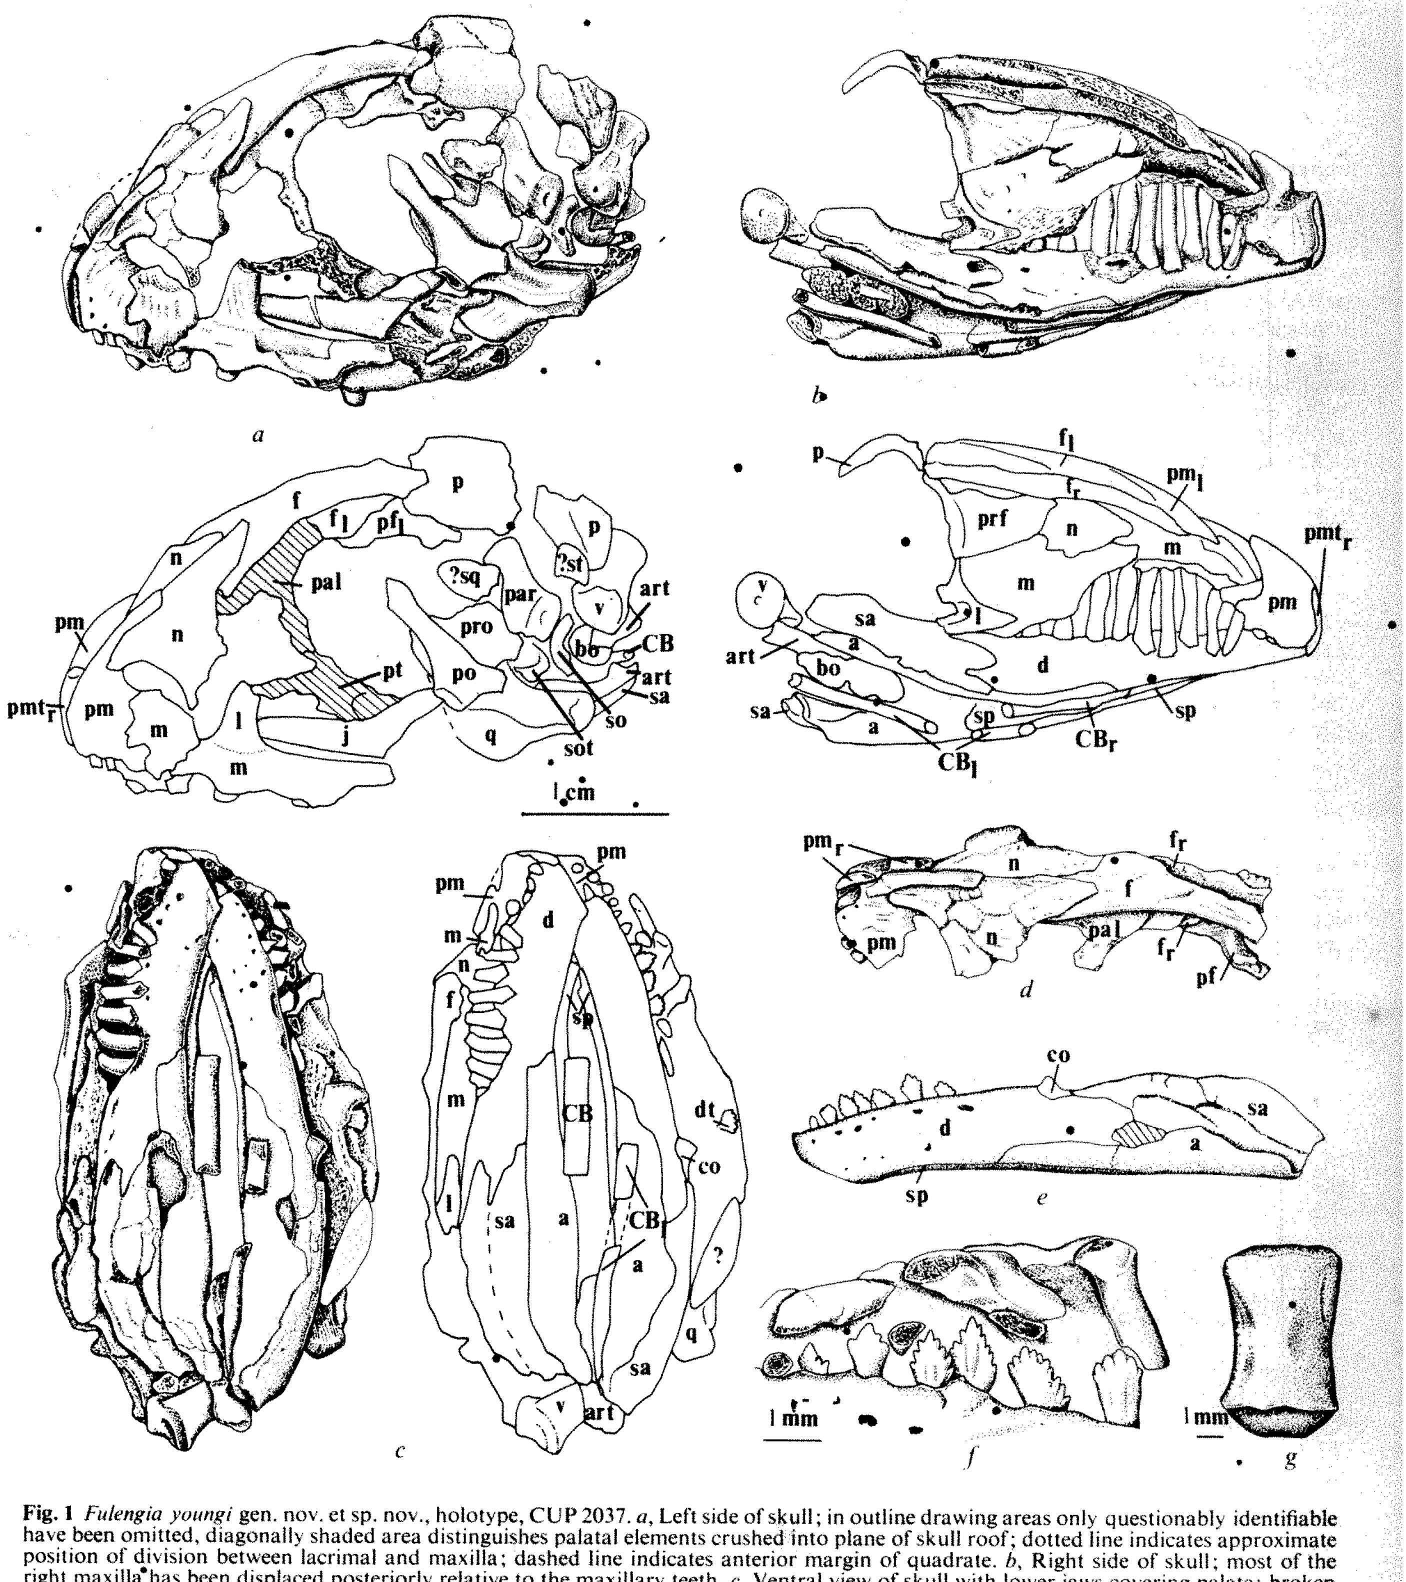

Fig. 1 *Fulengia youngi* gen. nov. et sp. nov., holotype, CUP 2037. *a*, Left side of skull; in outline drawing areas only questionably identifiable have been omitted, diagonally shaded area distinguishes palatal elements crushed into plane of skull roof; dotted line indicates approximate position of division between lacrimal and maxilla; dashed line indicates anterior margin of quadrate. *b*, Right side of skull; most of the right maxilla has been displaced posteriorly relative to the maxillary teeth. *c*, Ventral view of skull with lower jaws covering palate; broken line on surangular indicates normal dorsal extent of displaced angular. *d*, Dorsal view of anterior portion of skull. *e*, Lateral view of left lower jaw. *f*, Teeth of left dentary (below) and maxilla; teeth seen in section are from the more anterior portion of the maxilla that has been telescoped between the other elements. *g*, Associated vertebra in ventral view presumed anterior end uppermost. (*a–e*, ×2; *f*, ×8; *g*, ×4). a, Angular; art, articular; bo, basioccipital; CB, first certaobranchial; co, coronoid; d, dentary; dt, displaced tooth; f, frontal; j, jugal; l, lacrimal; m, maxilla; n, nasal; p, parietal; pal, palatine; par, paroccipital process; pf, postfrontal; pm, premaxilla; pmt, premaxillary tooth; po, postorbital; pro, proötic; pt, pterygoid; q, quadrate; sa, surangular; so, supraoccipital; sot, spheno-occipital tubercle; sp, splenial; sq, squamosal; st, supratemporal; v, vertebra; subscripts l and r refer to bones from left and right side where there is a possibility of confusion. In the case of the frontal, they indicate broken elements of a median bone.

frontal; paired premaxillae with long nasal processes; large upper temporal opening with a margin partially formed by the postfrontal; postorbital triradiate and nearly vertical; lateral articular surface of paroccipital process large, indicating support of quadrate and squamosal; lacrimal reduced; approximately five teeth in the premaxilla, nine in the maxilla and 13 in the dentary; teeth fully pleurodont, closely resembling those of the modern genus *Iguana iguana*; laterally compressed, cuspate crowns whose anterior margin is angled toward the midline; low coronoid process, approximately midway between articular and symphysis; splenial extending from behind coronoid to symphysis; vertebrae weakly procoelous; skull of only known specimen 38 mm long. The absence of comparative material from the early Mesozoic makes composition of a proper differential diagnosis impossible. There is no clear basis for determining which characters may be diagnostic at the level of species, genus or family, although it is probable that dental characteristics and relatively large size are typical of the species or genus, but not family. In spite of the probable exclusion of this genus from previously recognised lizard infraorders, we do not consider it desirable to create a new infraorder on the basis of a single incomplete skull.

The skull (Fig. 1) is flattened laterally and telescoped from back to front, as well as having some individual elements further displaced. Simmons[4] indicates that many specimens from this locality give the impression of being coprolitic; passage through the digestive system may account for the damage to this specimen. Although the bones identified in Fig. 1 are for the most part clearly defined, in other areas of the specimen it is not possible to differentiate bone from matrix. Some of the bones are broken and deeply fissured, but there is little difficulty in differentiating sutures from breaks.

The configuration of most of the bones of the roof of the skull can be seen from one side or the other. Important exceptions are the parietal and squamosal. The area of the parietal is too poorly preserved to show whether or not the bone is paired, but it appears to be fused medially. The parietal foramen appears to have been located at the juncture between the frontal and parietal. The position of the paroccipital process defines the extent and orientation of the squamosal, but the specific relationship with the quadrate (the dorsal portion of which is covered by the proötic and postorbital) cannot be determined.

With the exception of brief reference to more advanced forms[1], our knowledge of Late Triassic lizards is limited to the specialised gliding forms from Great Britain and North America in the family Kuehneosauridae. In spite of their extreme postcranial specialisation, these genera retain a skull morphology similar to that of the late Permian and early Triassic Paliguanidae[3] from South Africa. The oldest described members of the infraorders Gekkota, Iguania, Scincomorpha and Anguimorpha are from the late Jurassic of Europe and China[5]. The only living infraorder of lizards not recognised in the Upper Jurassic is the Amphisbaenia, known only since the early Tertiary[6]. Differentiation of the modern infraorders presumably began early in the Jurassic or even in the Upper Triassic.

Fulengia does not show the particular combination of features by which members of the Gekkota, Anguimorpha or Amphisbaenia are recognised. What is known of the skull, as restored (Fig. 2), resembles in a general way the pattern of primitive members of the Iguanidae, some large teiids and members of the extinct scincomorph families recently described from the Upper Cretaceous of North America and Mongolia[7]. Most of the features that it shares with these groups, however, are clearly primitive; for example, the presence of a large dorsal temporal opening, a complete postorbital bar and a vertically oriented, triradiate postorbital, and do not support assignment to any of these families. The massive lower jaw and the tiny coronoid distinguish this genus from members of all living reptile infraorders.

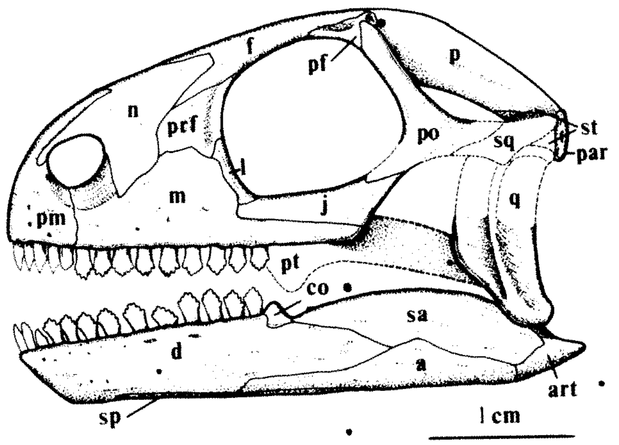

Fig. 2 *Fulengia youngi*, gen. nov. et sp. nov., reconstruction of the skull in lateral view ×2. Bones and teeth shown in broken lines are either missing or covered by other elements in the specimen. They are reconstructed on the pattern of the living *Iguana*. Abbreviations as in Fig. 1.

The dentition of *Fulengia* (Fig. 1*f*) is presumably a specialised characteristic and probably less important than the pattern of the skull bones in establishing infraordinal relationships. Multicuspate, laterally compressed tooth crowns similar to those of *Fulengia* are known in numerous living lizards belonging to diverse taxonomic groups. Where stomach contents have been studied[8], such a pattern is associated with a primarily herbivorous diet. Accepting a skull : trunk ratio similar to that of living iguanids with similar skull size[9] and length : weight ratios determined by Pough[10], the weight of this specimen would be approximately 80 g—towards the top of the range for primitive insectivores, but near the bottom of the range for herbivores[10]. Dental specialisation toward a herbivorous diet and relatively large size are features not expected in primitive lizards[10] and particularly not in the group(s) ancestral to the advanced infraorders, most of which are represented by small, apparently insectivorous, forms in the late Jurassic. The relatively large size of the skull was probably an important factor in its preservation, in view of the extremely poor fossil record of other, smaller, lizards in the early Mesozoic.

Fulengia itself can be viewed as a precociously specialised genus, divergent from the main line of lizard evolution. Other members of the family to which it belonged may have been closer to the ancestry of modern groups. The Fulengidae may (1) be related to the stock from which the known iguanians arose; (2) represent an earlier stage, close to the ancestry of most lizard infraorders, or (3) exemplify an independent achievement of some modern lizard features from the primitive eolacertilian stock. The absence of comparable forms in the Triassic and early Jurassic makes it difficult to establish the relationship of *Fulengia* more specifically.

We thank the Field Museum of Natural History for the loan of this specimen. This study was supported by grants from the Merrill Trust and the National Research Council of Canada.

Adaptive reduction in permeability of avian eggshells to water vapour at high altitudes

We report here the existence of an altitudinal cline in permeability of eggshells to water vapour for eggs of a North American species of bird. This pattern of geographic variation in permeability of eggshells seems to have arisen as an adaptive response to altitudinal variation in the diffusivity of water vapour through air. Diffusivity of atmospheric gases has not previously been widely recognised as an important component of the physical environment to which organisms are exposed, and our findings provide further evidence for the pervasiveness of natural selection.

A bird egg loses water continuously during normal incubation owing to the outward diffusion of water vapour through pores in the calcareous shell[1–3]. The loss of a certain amount of water from the egg is essential for the normal development and hatching of the embryo[4], for the escape of water allows an air space to form in the blunt end of the egg[5] and this space is the source of air for the first breaths taken by the embryo before hatching[1]. Reserves of water within the egg to support the metabolism of the developing embryo are fixed in amount, however, and the loss of large quantities of water from the egg could be detrimental[6]. Thus, porosity of the eggshell is delicately adjusted (in an evolutionary sense) to assure that only as much water is lost from the egg during incubation as is required for formation of an air space of the necessary volume[3,7].

Eggs laid by birds breeding at high altitudes face a potential disruption of the balance between water loss and water conservation[3], simply because molecules of water vapour diffuse more rapidly through air in conditions of low atmospheric pressure characterising high altitude environments than in atmospheric conditions of low altitudes[8]. Therefore, as a working hypothesis, we predicted that permeability of eggshells to water vapour is lower in eggs of birds breeding at high altitudes than in eggs of conspecifics breeding at low altitudes, thereby compensating for the increased diffusivity of water vapour in air at high altitudes.

During June 1976, eggs of barn swallows (*Hirundo rustica*) were collected from nests at nine localities along an altitudinal gradient running from the town of Crook in the South Platte River Valley of northeastern Colorado (elevation 1132 m), to South Park in the mountains of central Colorado (elevation 2883 m). The diffusivity of water vapour in air is approximately 25% higher at South Park than at low elevations in northeastern Colorado. Only one egg was taken from each nest because eggs of a single female are likely to have similar permeabilities to water vapour[9].

Following transport of the eggs to our laboratory at Colorado State University, the eggs were placed randomly in vented desiccators above flakes of potassium hydroxide to maintain a dry atmosphere[1]. The desiccators were held in a constant temperature cabinet at 25 °C, a temperature too low for embryogenesis to proceed[10]. Each egg was weighed six times on an analytical balance at approximately 24-h intervals, and the rate of weight loss—which we attribute largely to the escape of water vapour—was computed by a linear regression procedure. The volume of each egg was then measured by displacement of water, and its surface area calculated using the equation of Paganelli, Olszowka and Ar[11].

Assuming that the vapour pressure at inner surfaces of eggshells was 23.76 torr (that is, the vapour pressure of pure water at 25 °C)[12,13], the conductance of eggs to water vapour was calculated from the formula

$$G_{H_2O} = M_{H_2O}/\Delta P_{H_2O}$$

where G_{H_2O} is the conductance of an egg to water vapour (μg d^{-1} torr^{-1}), M_{H_2O} is the rate of water loss (μg d^{-1}), and ΔP_{H_2O} is the gradient in vapour pressure across the eggshell (torr). All values were corrected to sea-level pressure (ref. 8).

A regression analysis of variance (Table 1) revealed a linear decline in conductance of barn swallow eggs to water vapour with increasing altitude of the nesting site (Fig. 1). This reduction in water-vapour conductance of swallow eggs from montane localities is similar to that reported earlier for eggs of domestic fowl maintained for several generations at a high altitude[14], but differs from the latter in an important respect. Reduced conductance of eggs of domestic fowl at high altitude just compensates for the increased diffusivity of water vapour, resulting in total water losses from eggs during incubation that are similar to those experienced by eggs from low altitudes[14]. In contrast, the adaptive reduction in conductance of swallow eggs with increasing altitude of the nesting site is greater than that required simply to compensate for the increased diffusivity of water vapour at high altitude. For example, whereas a 17% reduction in conductance of swallow eggs would just compensate for the increased diffusivity of water vapour at 3000 m as compared to 1500 m, the observed reduction in conductance between these elevations is 59%.

Table 1 Regression analysis of variance of conductances of barn swallow eggs to water vapour in relation to altitude of the nesting sites

Source of variation	Sum of squares	d.f.	Mean squares	*F*-ratio	*P*
Linear regression	183,990	1	183,990	13.07	<0.005
Deviations from linearity	114,049	7	16,293	1.16	>0.25
Error	351,886	25	14,075		
Total	649,925	33			

This analysis indicates that a linear model is adequate to describe geographic variation in conductances of eggs to water vapour, and that the slope of the line is significantly different from zero.

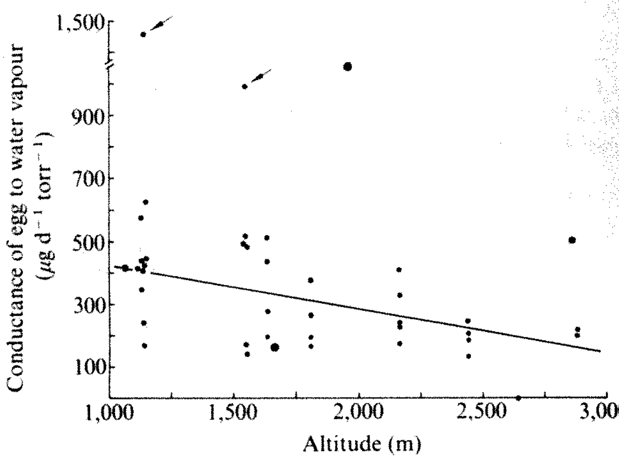

Fig. 1 Linear regression of conductances of barn swallow eggs to water vapour (corrected to sea-level pressure) against altitude of the nesting sites ($y = 564 - 0.140x$). The two extraordinarily high values identified with arrows represent eggs that probably suffered hair-line cracks during transport, and these values were not included in the analysis of variance (Table 1). Bartlett's test indicates that we are justified in assuming homogeneity of sample variances ($\chi^2 = 9.65$; d.f. = 8; $P > 0.1$). The correlation coefficient for the regression line is 0.53.

Adaptation of barn swallows to high altitudes differs from

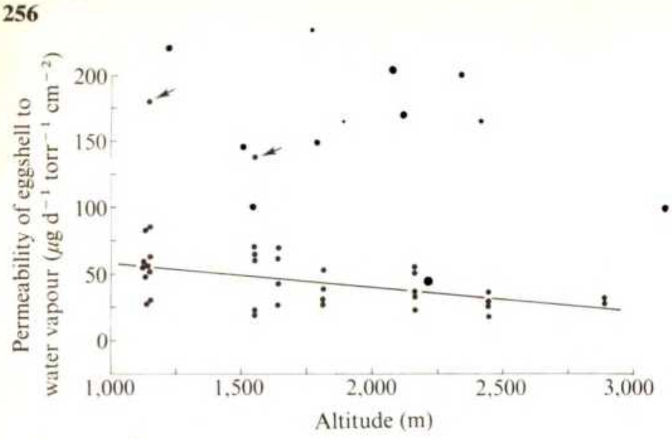

Fig. 2 Linear regression of permeabilities of barn swallow eggshells to water vapour against altitude of the nesting sites ($y=75.18-0.0176x$). Permeability of each eggshell was computed by dividing the conductance of the egg to water vapour by the calculated value for surface area[1]. The slope of the line is significantly different from zero ($F_{1,25}=11.67$; $P<0.005$), and the data do not depart significantly from linearity ($F_{7,25}=1.39$; $P\approx 0.25$). The correlation coefficient for the regression line is 0.50. Arrows identify the statistical outliers to which reference was made in the caption to Fig. 1.

the example of domestic fowl in another important way. Adaptive reduction in conductance of hens' eggs at high altitude stems from reductions both in size of eggs (and therefore in surface area) and in permeability of eggshells to water vapour[14]. In contrast, eggs of barn swallows do not vary in size among the populations sampled in this investigation ($F_{8,27}=1.49$; $P>0.1$), and the entire decline in conductance with increasing elevation is attributable to a parallel decline in permeability of eggshells (Fig. 2). Thus, domestic fowl and barn swallows exhibit different adaptive strategies in their responses to reduced atmospheric pressure.

The observed pattern of altitudinal variation in permeability of barn swallow eggshells to water vapour has important implications pertaining to the comparative biology of montane and piedmont populations of the species. For instance, eggs of various bird species experience a loss of water during incubation amounting to 14–18% of the weight at laying[3,7]. Assuming that eggs of barn swallows from montane and piedmont populations experience similar fractional weight losses prior to hatching, then incubation periods may be longer at high altitudes[3,14], or effective ventilation of nests may be increased at montane localities, thereby providing for lower vapour pressures in air adjacent to incubating eggs and for higher rates of water loss from eggs during natural incubation[7].

The porosity of avian eggshells apparently is a heritable characteristic[15]. The size and number of pores through an eggshell is established at the time of shell formation[9], and the permeability of the eggshell to water vapour remains constant throughout incubation[16]. When heritability of porosity is combined with a tendency for birds to return to the locality where they were born[17], it is possible for natural selection to act on variation in porosity of eggshells to effect a differentiation of populations with respect to this characteristic[18]. Presumably, this explanation accounts for the origin and maintenance of the clinal pattern of variation observed by us for eggs of barn swallows.

Dr T. J. Boardman advised us on statistical procedures, Dr D. L. Kilgore, Jr, and Mr R. K. Stiverson read a draft manuscript, and Mr J. R. Sotherland helped us to collect the eggs. This work was supported by the NSF.

Virus-like particles in the nematode *Romanomermis culicivorax* (Mermithidae)

EARLY reports of virus infections of nematodes remain unconfirmed[1,2], although more recently virus-like particles were reported occurring in the intestinal cells of a plant-parasitic nematode[3]. The only confirmed reports of viruses found inside nematodes are plant viruses which occur in the digestive tracts of their nematode vectors[4]. We report here the presence of virus-like particles in cells of the infective stages of the mosquito parasitic nematode, *Romanomermis culicivorax*.

Cultures of *R. culicivorax* Ross and Smith (*Reesimermis nielseni* Tsai and Grundmann) had been cultured *in vivo* in larvae of the mosquito *Culex pipiens quinquefasciatus* Say.

Cultures containing eggs of the nematode were flooded with water and yielded preparasitic (infective stage) juveniles that were prefixed for 1 h in phosphate-buffered 1% gluteraldehyde then transferred to a 1% solution of osmium tetroxide. They were then placed in agar blocks, dehydrated in an ethanol series and double embedded in Araldite. Sections made on a Porter–Blum microtome were stained with uranyl acetate and examined with a Philips EM 300 electron microscope.

Each of 10 preparasitic juveniles of *R. culicivorax* examined contained virus-like particles in the hypodermal cords, cells

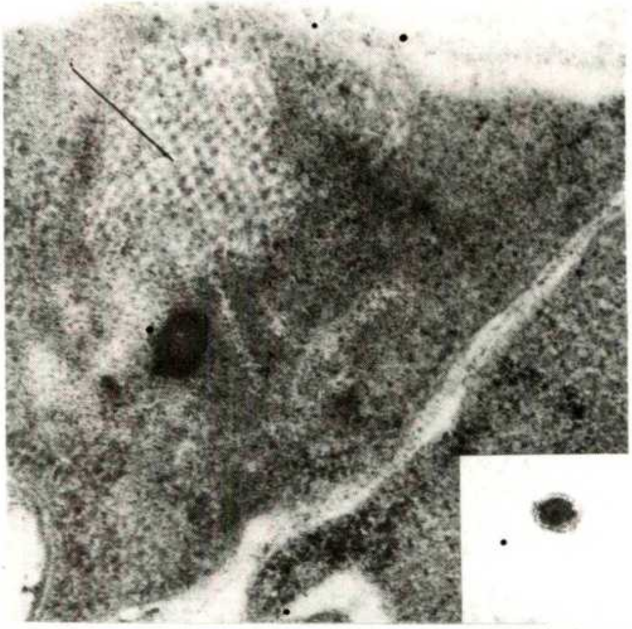

Fig. 1 Crystalline array of virus-like particles (arrow) in hypodermal cord of preparasitic juvenile of *R. culicivorax* (× 50,000). Insert shows isolated virus-like particle with inner core and outer envelope (× 100,000).

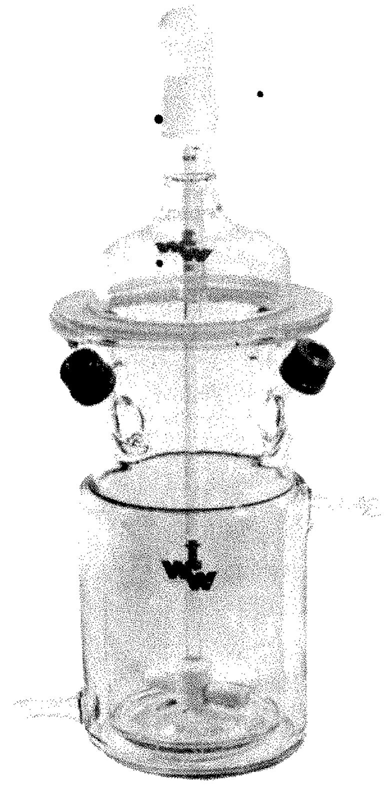
LEADING UK MANUFACTURERS OF

Spinner for Tissue Culture



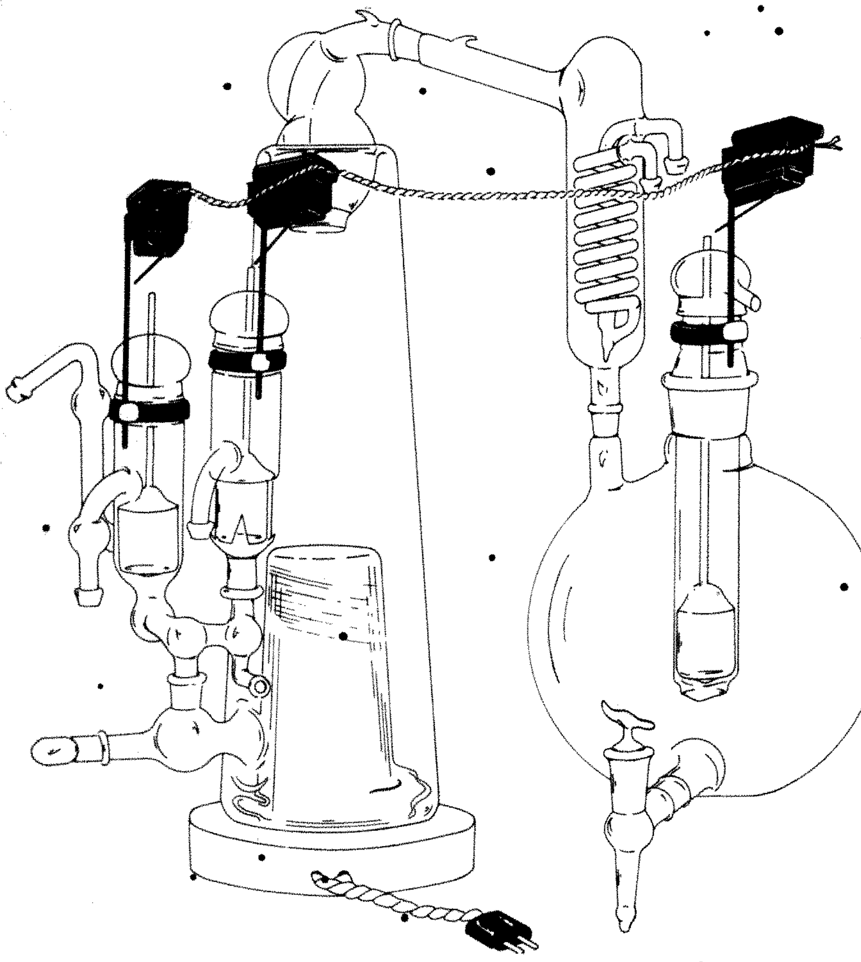
A Water Jacketed Culture Spinner Vessel, the use of which is a very efficient method for the culture of a wide range of cell types that do not need to adhere to a surface for their proliferation. It has been used successfully for the culture of a variety of animal as well as human cells which were derived from normal and malignant tissue. For example, for the culture of cells derived from human osteosarcoma, rhabdomyosarcoma and Rous sarcoma virus transformed cells. In addition it has been used for the culture of human leukaemic cells, lymphoblasts from normal individuals and murine plasmacytoma cells. In each case the cells have had to be established and actively proliferated in vitro before they could be transferred to the spinners, which then have provided the most efficient way for large-volume culture with a very high percentage of viability.

The spinner has a double wall for use as a water jacket for the temperature control of cultures outside an incubator. A water circulator is necessary in this case to give a sufficiently rapid water flow for close temperature control, though the same circulator may serve several spinners. For each spinner a magnetic stirrer is needed to ensure continuous mixing of the cell suspension.

Each spinner can be provided with four openings. For example,

1. an opening for the continuous supply of the appropriate gas mixture into the culture environment. (In order to avoid contamination the gasses should pass through a sterile cotton-plug filter.)
2. an outlet for pressure equalisation. (This, too, should have a sterile cotton-plug filter.)
3. an outlet with a glass tube to the bottom of the vessel for drawing-off quantities of cell suspension under sterile conditions.
4. an opening for the addition of culture fluid (with or without use of a peristaltic pump). This is not essential under normal growth conditions since the culture media can be added through the top opening.

Circle No. 17 on Reader Enquiry Form.



The SCORAH Automatic Electric all glass WATER STILL (patented)

Automatic Can be left on without attention. Heater current cuts off if water supply is interrupted, or inadequate or forgotten. When receiver (5 litres capacity) is full, current cuts off. When distilled water is drawn from receiver, the still resumes operation until receiver is refilled.

Purity Electrostatically charged condenser droplets can pick up fumes, dust and air-borne organisms from the laboratory atmosphere. The design of the receiver vessel ensures absence of such contamination.

Efficiency Heater of Scorah design and manufacture, consumption 1,700 watts, output 2.4 litres per hour (the full theoretical yield). Cost less than 2p per gallon at ½p per unit.

Safety The heating element is out of contact with the feed water, thus eliminating danger from "live" water supply or electrolytic effects of "burn out".

Assembly No retort stands of clamps are required. The 2½-in. diameter ball joint gives a stainless set-up. Outlet cap on boiler for quick periodical drain-off of sediment. The still may be installed on a shelf or platform about 1 ft. above bench level near a sink and enclosed in a transparent plastic cover to keep out dust.

Heat-resisting glass. Interchangeable ground glass joints.

associated with the amphidial nerves, and spaces of the pseudocoelom. The particles were isometric, developed in the cytoplasm and those found outside the cell were enveloped (Fig. 1 insert). The diameter of the enveloped particles was approximately 50 nm while core (without envelope) measured 33 nm. In the host cells, the particles were either arranged in a crystalline array or randomly in the cell (Fig. 1). In those cases where development occurred in the hypodermal cords, damage to the latter was evident through cell disruption and lysis. Other stages of the nematode have not yet been examined for the presence of similar particles. The virus-like particles could be restricted to this or other nematodes or they could have been originally acquired through contact with mosquito larvae.

If the particles are infective, they would have to be transovarially transmitted in the nematode because the chances that they were acquired during nematode development in the egg or in the short time the preparasitic had emerged from the egg are very slight.

The fact that *R. culicivorax* is being commercially produced for widescale release in gardens and the field clearly amplifies the importance of this discovery. Damage to the hypodermal cords by the virus-like particles could lower the efficiency of this nematode as a biological control agent.

Nitrogenase activity of endophyte suspensions derived from root nodules of *Alnus, Hippophaë, Shepherdia* and *Myrica* spp.

STUDIES of nitrogenase of root nodule homogenates have focused chiefly on the *Rhizobium*–legume system. Little is known about the nitrogenase of actinomycete-like endophytes of root nodules on woody, non-leguminous plants. Although nitrogen fixation has been reported in suspensions of the endophyte from *Myrica cerifera*[1,2], the results were either of very low significance or irreproducible. In both cases dithionite and oxygen were added, which seems to be contradictory Subsequent attempts to detect nitrogen fixation in non-leguminous nodule homogenates have been unsuccessful and investigations stopped at an early stage. We have found[3], however, that reasonable levels of acetylene reduction by nodule homogenates of *Alnus glutinosa* can be measured if 0.3 M sucrose and 0.1 M dithionite are present during anaerobic homogenisation. The latter was essential because the nodule material contains large amounts of phenolic compounds, which after oxidation inhibit nitrogenase activity. While determining optimal conditions for the nitrogenase assay it was found that the reaction was ATP-dependent but that addition of an ATP-generating system (creatine phosphate (Cr ~ P)/creatine phosphokinase) decreased the activity during short-term experiments. This inhibitory effect was not found when the same ATP-generating system was added to bacteroid suspensions derived from leguminous nodules We report here the seemingly aberrant behaviour of the added ATP-generating system, the applicability of our method to other actinomycete-woody plant symbioses, and the separation of actively acetylene-reducing endophyte material from nodule homogenates.

To get a better insight into the effect of an added ATP-generating system on the nitrogenase activity of endophyte suspensions of *A. glutinosa*, the reaction was followed over an extended period. As an ATP-generating system we used phospho(enol)pyruvate (PEP) and pyruvate kinase (PK) Figure 1 shows that between 30 min and 8 h acetylene was reduced at equal rates when either ADP or ATP was added to nodule homogenates with PEP and PK. Because ADP only produced no nitrogenase activity, we concluded that the ATP-generating system can function in nodule homogenates of *A. glutinosa*. Within the first 2 h, however, the rate of acetylene reduction in complete systems was lower than that in the control. These results show that at least during the first 2 h of incubation there was no apparent inhibition of nitrogenase by ADP produced from ATP. This is in contrast to results obtained with bacteroid suspensions derived from leguminous nodules[4,5].

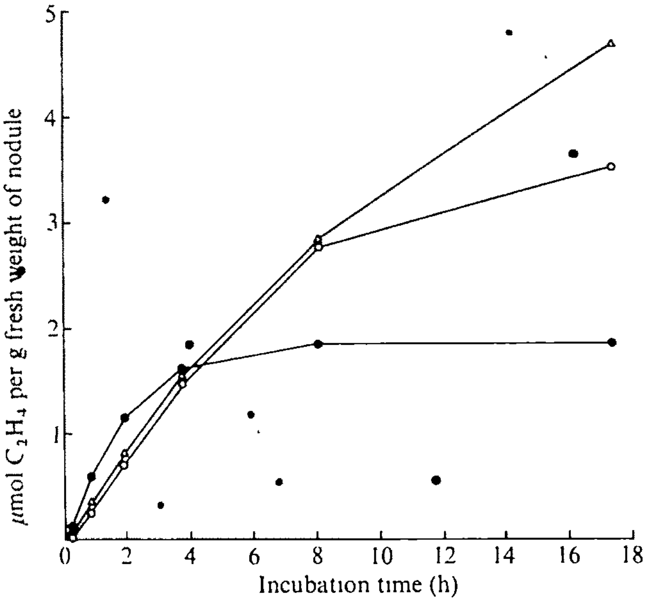

Fig. 1 Effect of PEP (10 mM) and PK (0.01 mg ml^{-1}) on acetylene reduction by nodule homogenate of *Alnus glutinosa*. General procedure for homogenisation, filtration and incubation as described previously[3], with the following modifications: 2 min homogenisation at 31,000 r p m in the presence of 100 mM dithionite. The 100-μm filtrate is referred to as the nodule homogenate. The assay mixture (2 ml) contained 1 ml of filtrate (corresponding to 14 mg of fresh nodule tissue), 2% PVP, 0.15 M sucrose, 100 mM $Na_2S_2O_4$, 2.5 mM 1,4-dithioertythritol, 50 mM Tris–HCl (*p*H 8.0), and 5 mM $MgCl_2$ Where added, ATP and ADP were 5 mM △, ATP, PEP and PK, ○, ADP, PEP and PK, ●, ATP.

It was not clear why addition of the ATP-generating system initially inhibited nitrogenase activity (Fig. 1), and so the effect of the high-energy phosphate donor was tested. Table 1 shows that

§Calculated per g fresh weight of nodule

both $Cr\sim P$ and PEP inhibited acetylene reduction. The concentrations used were rather low compared with those given in the literature concerning ATP-generating systems for measuring *in vitro* activity of nitrogenase (38–50 mM $Cr\sim P$ (refs 4, 5)) Higher concentrations inhibited the activity even more. The nature of this inhibition is not yet known.

Since addition of an ATP-generating system had no positive effect in short-term experiments we tried to enhance acetylene reduction with increasing ATP and Mg^{2+} concentrations (Fig. 2). Maximum levels of activity were achieved at 10 mM ATP ($ATP/Mg^{2+} = 1$). There was no significant difference (0.01 level of significance) in activity when the concentrations were increased two or fivefold. The values for nitrogenase activity shown in Fig. 1 are considerably higher than those reported earlier[3], when suboptimal levels of ATP and Mg^{2+} were used.

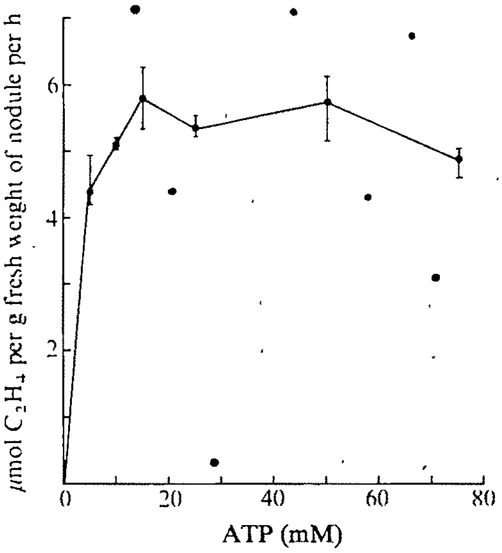

Fig. 2 Effect of ATP concentration on acetylene reduction by nodule homogenate of *Alnus glutinosa* $ATP/Mg^{2+} = 1$ Vertical brackets denote the extreme range of four replicates.

Using a constant ATP concentration of 15 mM we tested the applicability of our homogenisation and incubation method to a series of actinomycete–plant symbioses Because of the unexpectedly high optimum concentration of dithionite for *A. glutinosa*, we tried a range of concentrations. Table 2 shows that significant nitrogenase activities of nodule homogenates of various species can be demonstrated in this way and the optimum dithionite concentration seems to be different for these four types of nodules The differences in recovery (±25% for *Alnus* and *Hippophae* spp, and ±40% for the other two species) result from the differences in activity of the detached nodules This conclusion is based on observations with alders.

To study the metabolic processes in the endophyte, it is necessary to separate the intact endophyte from the host The most prominent structures of the endophyte are the vesicle clusters As these clusters show a strong tetrazolium-reducing activity it has been suggested[6] that they might also be involved in nitrogen fixation. We have developed a method to collect and purify these structures by anaerobic filtration of nodule homogenates[3,6].

In preliminary experiments, however, acetylene reduction by the fraction containing the vesicle clusters was less than 5% of the activity of the nodule homogenate[3] We have now found that the homogenisation procedure used previously was too rough and too many vesicle clusters were disintegrated. Using a milder procedure (Virtis 45 homogeniser, 4 min at 3,000 r.p.m) more vesicle clusters remained intact. Fractionation was improved further by collecting the vesicle clusters on a 10-μm filter By homogenising nodules of *A glutinosa* in this way, an activity of 2.59 μmol of C_2H_4 (calculated per g fresh weight of nodule per h, being 60% of the activity of the nodule homogenate) was obtained by the resuspended residue from the 10-μm filter. The 10-μm filtrate, consisting of hyphal fragments, disrupted vesicle clusters and plant cell debris, contained 29% of the activity of the homogenate, which was all particle bound. The remaining 11% of the activity was lost during the procedure. Results were similar with *Hippophae rhamnoides*, although the activity of the resuspended residue from the 10-μm filter was only 35% of the activity of the nodule homogenate. We think that the high recovery of nitrogenase activity in the fraction containing the vesicle clusters is an additional indication that nitrogenase is indeed located in the vesicle clusters.

As it is now possible to collect metabolically active vesicle clusters on a large scale, attention will be focused on these structures. Their relatively high nitrogenase activity *in vitro* opens the way for further physiological and biochemical studies

Adenylate cyclase activity oscillations as signals for cell aggregation in *Dictyostelium discoideum*

As well as acting as a chemotactic factor[1] cyclic AMP stimulates cells of *Dictyostelium discoideum* to differentiate after the end of growth into aggregation-competent cells. These differentiation signals have a temporal pattern: pulses are efficient signals, whereas continuous administration of cyclic AMP may even have an adverse effect[2-4]. *D. discoideum* cells can release cyclic AMP spontaneously as reiterated pulses[4], and also release cyclic AMP in response to extraneous cyclic AMP pulses[5-7], which is important for the transmission of signals in aggregation territories in form of propagated waves[8-12] The pulsatile release of cyclic AMP into the extracellular space is preceded by a sharp (about 10-fold) increase of its intracellular concentration within 1 min (ref 4) This indicates that the oscillating variable is not only transport but also net synthesis of cyclic AMP The periodic rise of the intracellular cyclic AMP concentration could be due to periodic activation of adenylate cyclase, to inhibition of phosphodiesterase, or to the oscillatory control of both enzymes. We present here evidence for sustained oscillations of the adenylate cyclase activity in signalling cells. No concomitant changes of the ATP concentration, the substrate of adenylate cyclase, were found.

Periodic activities can be recorded in *D. discoideum* by measuring the light scattering of cell suspensions[13]. These measurements provide reference points for correlating the adenylate cyclase activities in different phases of a cycle with changes in cyclic AMP concentration in living cells.

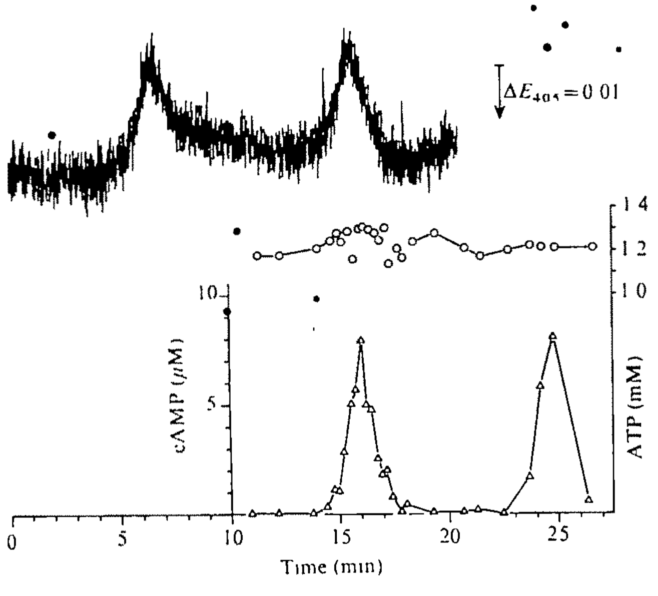

Fig. 1 Cyclic AMP (△) and ATP (○) concentrations in periodically signalling cells Changes of light scattering (top) indicate periodic activities in the cell suspension At intervals of 9 min the total cyclic AMP increases up to a sharp peak, whereas ATP in the same cells does not show significant oscillations. Because in the extracellular space cyclic AMP is rapidly degraded by phosphodiesterase[22], the cyclic AMP is predominantly intracellular and has been calculated like ATP per volume densely packed cells (left and right ordinates) Cyclic AMP was assayed by Gilman's[23] method after the addition of 5% TCA to 50 μl-samples of the cell suspension, and handling of the material as described by Gerisch and Wick[4]. ATP was extracted from suspended cells with 3% perchloric acid and determined by the bioluminiscence assay[24]. Cells of the axenic strain Ax-2, clone 206, were used 5 h after their transfer from growth medium into non-nutrient buffer. The cell density was 5 × 10[7] per ml, other conditions and light scattering measurements were as described before[13].

Spikes of decreased light scattering coincide with peak concentrations of cyclic AMP[4]. ATP concentration, measured simultaneously, did not oscillate detectably (Fig. 1): the steady-state ATP concentration was 150-fold higher than the cyclic AMP peaks. The depletion of the ATP pool of the cells due to cyclic AMP synthesis is therefore negligible, and should be rapidly compensated by respiratory control. The possibility remains that ATP, being compartmentalised, oscillates with larger amplitudes at the location of adenylate cyclase than it does on average in the whole cell.

The cyclic AMP concentration rises for not longer than 2 min in each cycle (Fig. 1), indicating similarly short phases of adenylate cyclase activation. Using the method of Salomon *et al.*[14], we reduced the assay time to 15 s, facilitating the detection of periodic short-term increases of the adenylate cyclase activity (Fig. 2). During the enzyme assay any regulatory influences due to varying concentrations of either the substrate or the product in different phases of a cycle were eliminated by adding both ATP and cyclic AMP in sufficiently high concentrations to cell homogenates.

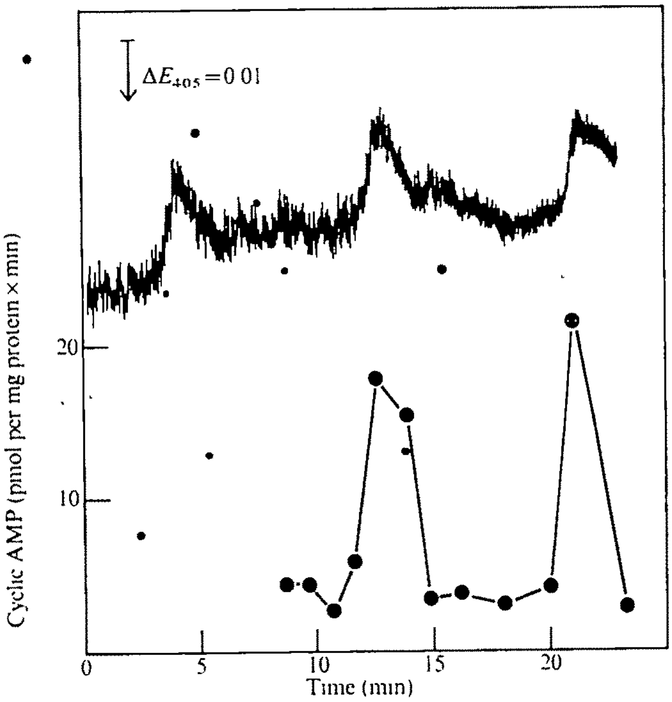

Fig. 2 Oscillations of adenylate cyclase activity in a cell suspension. Samples for the adenylate cyclase assay (bottom) were taken during continuous recording of light scattering (top). The cells were cultivated and prepared as described before[13] and used 4 h after transfer from growth medium into non-nutrient buffer. The strain was Ax-2 clone 206, and the cell density 1 × 10[8] ml^{-1}. The adenylate cyclase assay was performed according to Salomon *et al.*[14] after sonication of the cells for 5 s as described by Roos and Gerisch[16] The ATP concentration was 0.18 mM, the cyclic AMP 1 mM, and homogenate protein 1 mg ml^{-1}.

High enzyme activities in homogenates, and cyclic AMP peaks in intact cells were seen during the same part of a cycle, as indicated by the coincidence with the spikes of decreased light scattering in cell suspensions (Figs 1 and 2). In each period the enzyme stayed activated for 2–3 min, as expected from the length of time during which the cyclic AMP concentration rises in intact cells. The adenylate cyclase then returned to basal activities (Fig. 2), in accord with the sharp fall of the cyclic AMP concentration in living cells (Fig 1). The latter certainly results from deactivation of adenylate cyclase, from cyclic AMP transport into the extracellular medium[4], and perhaps to a minor extent from the action of intracellular phosphodiesterase.

In homogenates the activated state of the adenylate cyclase decayed within 1 min (Fig. 4). It remains to be seen whether the mechanism of deactivation is the same in the homogenate as in intact cells It is obvious, however, that degradation of adenylate cyclase is not the reason for the decay of its peak activities in homogenates, since the basal activity remained almost constant for a longer period (Fig. 4).

From measurements on 6 cycles a mean basal activity of 4.2±0.8 pmol cyclic AMP per mg protein per min was obtained, and a mean activation during pulse formation by the factor 7 1±1 6 (Fig. 3) In the best cases the amplification factor was 10, and the peak activities were 40–50 pmol per mg protein per min. These adenylate cyclase activities obtained in cell homogenates are comparable with the rates of cyclic AMP increase measured in living cells. A maximal rate of about 70 pmol per mg protein per min can be calculated from Fig. 1. Previously reported values have been not higher than 300 pmol per mg protein per ml (ref. 15).

What are the mechanisms of adenylate cyclase regulation? In cells which have not yet started to oscillate, adenylate cyclase is transiently activated by pulses of extraneous cyclic AMP which acts on cell surface receptors[16]. In spontaneously oscillating cells a postive feedback loop may connect cyclic AMP release, the activation of cell surface receptors, and the activation of adenylate cyclase. In fact, precocious pulses and phase shifts induced by small pulses of extraneous cyclic AMP, demonstrate a connection between the receptors and the system that periodically activates adenylate cyclase[13] This focuses attention on the regulatory pathway from the cell surface receptors to adenylate cyclase. One possibility is that upon receptor activation a soluble intracellular effector is formed, alternatively the enzyme might undergo covalent modification, for example by phosphorylation. Calcium, which at high concentrations inhibits adenylate cyclase[17] is a possible soluble effector. It seems unlikely, however, that periodic calcium sequestration is the mechanism which causes the enzyme activity to oscillate. Calcium 8 5 mM inhibited the adenylate cyclase in both its activated and non-activated state EGTA 3 mM did not prevent the decay of the activated state in cell homogenates Furthermore, when added to a homogenate with basal adenylate cyclase activity, EGTA did not activate the enzyme An earlier report[18] on the activation of adenylate cyclase by 5′-AMP has not been confirmed by recent work[16,17]

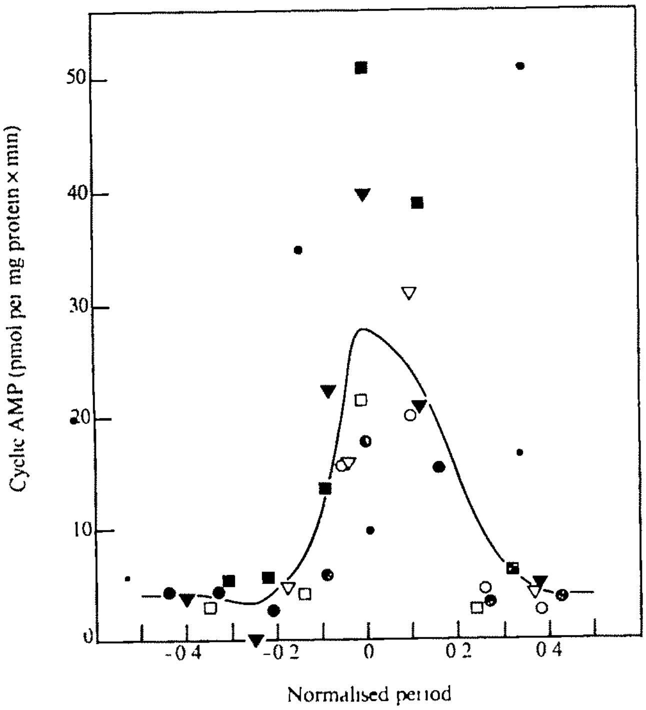

Fig. 3 Time course and amplitude of adenylate cyclase activation as the average (smooth curve) from 6 spontaneous pulses (symbols). The mean period was 7.8±0.7 min. The periods were normalised and adjusted to the peaks of decreased light scattering (zero time). Methods were as in Fig. 2 Cells of clones 206 or 214 of strain Ax-2 were used at 3–4 h after replacement of the growth medium by non-nutrient buffer.

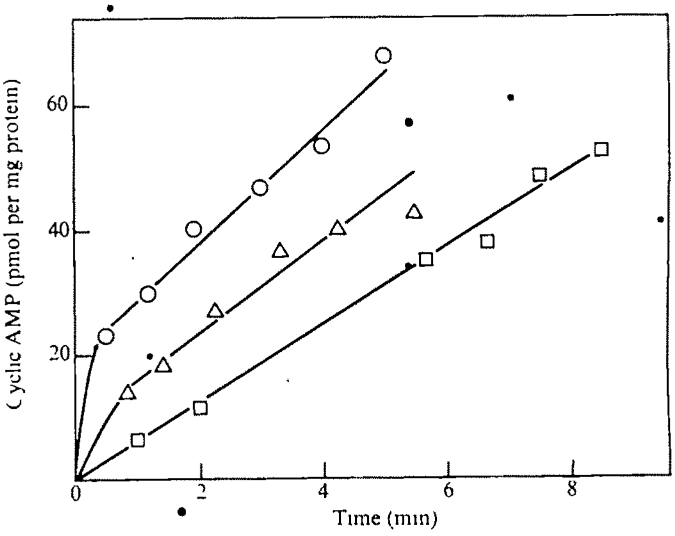

Fig. 4 Cyclic AMP synthesis in homogenates prepared at a peak of adenylate cyclase activity (○), at the phase 3 min before (□) and in a 1 : 1 mixture of both (△) The initial rate of synthesis in the mixture was the average of the basal activity found in the non-activated state, and of the high initial rate characteristic of the activated state. The activity remaining after the decay of the activated state was similar to the basal activity. Methods were as for Fig. 2, except that the concentration of ATP was 0.5 mM, and of protein 1.8 mg ml^{-1}.

To test for any soluble effector, homogenates containing activated and non-activated adenylate cyclase were mixed. The enzyme activity in such a mixture was the average of the activities in the individual homogenates (Fig. 4). This renders the presence of a soluble activator or inhibitor in homogenates from either one phase of the cycle unlikely, and favours the possibility of reversible covalent modification of adenylate cyclase.

In summary, the periodic activation of an enzyme, adenylate cyclase, is a key event in the generation of intercellular signals in *D discoideum*. The finding that the total cellular ATP does not oscillate except within the limits of experimental error, poses certain restrictions on an allosteric model of adenylate cyclase oscillations in which substrate oscillations are essential[19] The *D. discoideum* oscillator differs from chemical and biochemical oscillating systems, like the Belousow–Zhabotinsky reaction[20] or glycolysis in yeast extracts[21], in that it is composed of two compartments separated and connected by the cell membrane. In these compartments cyclic AMP oscillates with different amplitude and phase[4] Cyclic AMP is produced intracellularly, is then released into the extracellular space, from where it feeds back to its own synthesis via cell surface receptors. This opens the possibility that the cell membrane constitutes an integral part of the oscillator, functioning both in cyclic AMP transport from the inside to the outside, and as a signal transducing element in the opposite direction.

Bacterial tumble regulator may be inactivated by methylation

KORT *et al.*[1] have described the methylation of a membrane protein which seems to be involved in bacterial chemotaxis: they show that addition of attractants affects the methylation, that the source of the methyl group is methionine, a compound required for chemotaxis, and that certain non-chemotactic mutants fail to carry out the methylation reaction. There is no relationship, however, between the amount of methylation and the tumble frequency, and the exact role of this methylation, therefore, remains mysterious Control of the tumbling process is essential for chemotaxis; peritrichous bacteria swim in short straight-line runs that are separated by abrupt changes of direction (tumbles). In the presence of attractants, however, the tumbling frequency either decreases or increases as the bacterium swims up or down the concentration gradient, respectively[2] Runs are due to counter-clockwise rotation of the flagella, whereas clockwise rotation causes tumbling[3] Aswad and Koshland[4] have proposed the existence of a "tumble-regulating substance" that would control the direction of the rotation· clockwise rotation of the flagella (and therefore tumbling of the bacteria) occurring when the concentration of this regulating substance falls below a certain threshold. The same authors have suggested that *S*-adenosyl-methionine, the product of the reaction of one molecule of methionine with one molecule of ATP[5], might be necessary for the degradation of the tumble regulator I propose that the methylated protein described by Kort *et al.*[1] may be the inactivated tumble regulator.

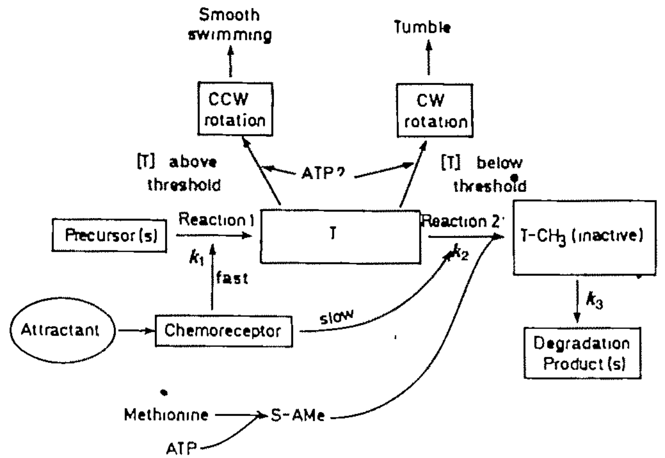

Fig. 1 Proposed scheme for inactivating tumble regulator T, tumble-regulating protein, T-CH$_3$, methylated protein, S-AMe, *S*-adenosyl-methionine; CCW, counterclockwise, CW, clockwise ATP?, ATP may be necessary for the direct control of the direction of flagella rotation[2]

Table 1 Effect of mutational changes of k_1, k_2 and k_3 on swimming behaviour and methylation

Mutation		[T]	Mobility	[T-CH$_3$]
k_2 ↑		↑	Smooth	↑
k_2 ↓		↓	Tumbling	↓
k_1 ↑		↓	Tumbling	Normal
k_1 ↓		↑	Smooth	Normal
k_3 ↑		—	Normal	↓
k_3 ↓		—	Normal	↑
k_1 and ↑ k_2	k_1/k_2 unch	—	Normal	↑
	k_1/k_2 ↑	↑	Smooth	↑
	k_1/k_2 ↓	↓	Tumbling	↑
k_1 and ↓ k_2	k_1/k_2 unch.	—	Normal	↓
	k_1/k_2 ↑	↑	Smooth	↓
	k_1/k_2 ↓	↓	Tumbling	↓
k_2 ↓, k_3 ↓		↓	Tumbling	↑
k_2 ↓, k_3 ↑		↑	Smooth	↓

T, tumble regulator, T-CH$_3$, methylated tumble regulator, Pr, precursor(s), S-AMe, *S*-adenosyl-methionine, unch, unchanged At the steady state

$$[T] = k_1[Pr]/k_2[S\text{-}AMe] \quad [T\text{-}CH_3] = k_1[Pr]/k_3.$$

Mutations implying other combinations of constant variations can be visualised as well as mutations influencing the concentrations of S-AMe and of the precursor(s)

In my proposed scheme, I have made use of the mechanism described by Macnab and Koshland[6] and by Springer *et al.*[7]—that combination of an attractant with the chemoreceptor increases k_1 rapidly and k_2 slowly This causes a transient increase in the concentration of the tumble regulator and, consequently, a transient repression of the clockwise rotation of the flagella (and thus of the tumbles).

My general scheme offers an explanation for the following experimental facts The effect of methionine starvation on methionine auxotrophs[1,4,7,8] or of the addition of arsenate to wild strains[9] is that no *S*-adenosyl-methionine is formed: reaction 2 does not take place, protein T accumulates and the bacteria do not tumble Accordingly, no methylated protein is formed and no chemotaxis can take place, which is in agreement with experimental data.

Variation of the constants k_1, k_2 and k_3 may explain the occurrence of the various types of mutants described by Kort *et al.*[1] (see Table 1) Tumbling mutants with increased methylation and smooth-swimming mutants with decreased methylation are the most difficult to account for, as one must assume the concomitant variation of two of the three constants involved.

As a consequence of the increase in both k_1 and k_2, induced by the addition of an attractant[6,7], the concentration of the methylated protein also increases, as observed by Kort *et al.*[1]. The observation, however, that, within 10 min, the concentration of the methylated protein returns to its steady-state level, remains unexplained.

If my proposed idea is true, that methylation of the tumble regulator by *S*-adenosyl-methionine causes its inactivation, then it seems that the same principle has been utilised much later in evolution, since it is known that adrenaline and noradrenaline are inactivated by catechol-*O*-methyl transferase, an enzyme which utilises *S*-adenosyl-methionine as a methyl donor[10,11].

I thank Professor J. M. Ghuysen for help in preparing the manuscript

Mucosal penetrability enhanced by serum-derived antibodies

ALTERED mucosal penetrability for food constituents and microbial components probably underlies the pathogenesis of a variety of diseases occurring in mucous membranes and distant sites such as liver and joints[1]. The secretory immune system seems to be of major importance in mucosal exclusion of foreign material and is stimulated by topical antigens[2]. Conversely, parenteral immunisation almost exclusively gives rise to circulating antibodies which are chiefly of the IgG class. IgG is not a secretory immunoglobulin in man, monkey, rabbit and guinea pig[3], and contradictory information has been published about the effect of parenteral immunisation on the absorption of antigen through mucous membranes. Moreover, a possible influence on the concurrent mucosal penetration of unrelated macromolecules has not been considered previously. We report here that although serum-derived antibody retards the penetration of corresponding antigen, it nevertheless causes impairment of the mucosal barrier. Induction of IgG antibodies may thus cause hazardous side effects by altering mucosal penetrability.

Mucosal specimens devoid of a secretory immune system were obtained from the lingual frenum of 16 adult Belted Dutch rabbits, 8 of which had been immunised subcutaneously over a period of 2–3 months with a total of five 3-mg doses of human albumin emulsified in complete Freund's adjuvant. This schedule resulted in high levels of precipitating serum antibody (Table 1), which by immunoelectrophoresis was shown to be located chiefly in the IgG fraction. The excised membranes were rinsed in saline and mounted in diffusion chambers[4] with the oral side exposed to 1 ml tissue culture medium containing 30 mg human albumin and 30 mg human transferrin, and with the basal side exposed to 200 μl medium alone. After incubation for 2 h in a humid atmosphere of CO_2 in air at 37 °C, the basal concentrations of albumin and transferrin were measured. In preliminary experiments this was attempted by isotope labelling which, however, was found to be unreliable[5]. Since radioimmunoassay has also been found unreliable in similar experiments[6], the two components were quantified by single radial immunodiffusion performed essentially as described before[7]. To obtain sufficient sensitivity (detection limit of about 0.25 μg ml^{-1}), specific rabbit antisera were used at final dilutions of 1:300 (anti-albumin) and 1:160 (anti-transferrin) in the Agarose gel, and the 5-μl sample wells were refilled three times. The precipitin rings were intensified by overlaying the gel with filter paper soaked in 1:3 dilution of goat antiserum to rabbit IgG.

Table 1 shows that the control membranes discriminated between albumin and transferrin, according to the difference in molecular weights (69,000 and 90,000), as reported for other biological membranes *in vivo*[8]. This held true even for the specimen showing exceptionally high penetrability. Its defect was probably restricted to an epithelial damage, since penetration studies with rabbit intestinal mucosa have indicated that molecular selection takes place at the basement membrane whereas the epithelial layer is solely rate limiting[9].

The penetration of albumin through membranes from immunised animals was reduced whereas the concurrent penetration of transferrin was enhanced (Table 1). The former result supports previous experiments performed with intestinal and oral mucosa of parenterally immunised animals[10,11], and may be ascribed to immune complex formation. Binding of antigen to antibody in the mucus covering the intestinal surface has been suggested[12], whereas for the oral mucosa (gingival crevicular epithelium) ultrastructural indication of immune complex formation within the epithelial interstices has been presented[11]. Ultrastructural studies of small intestinal mucosa, however, have indicated increased antigen absorption into epithelial cells after parenteral immunisation[13].

Thus, the level at which serum-derived antibody retards mucosal antigen penetration has not been clearly defined. Since some IgG diffuses through epithelial interstices[14,15], immune complexes could be formed at the epithelial level, but also in the connective tissue. Exposure of epithelial surfaces to antigen in sensitised animals results in a rapid local emigration of neutrophils[11,16]. Phagocytosis of immune complexes and degradation of antigen could therefore contribute to the apparently retarded mucosal antigen penetration. Moreover, release of enzymes from these cells probably explains the most important finding in our experiments—the enhanced penetration of an unrelated macromolecule. It is well known that neutrophil lysosomal enzymes can

Rabies – The Facts

Colin Kaplan and others

In a world afflicted by countless varieties of disease, rabies stands out as uniquely terrifying. This book presents the biological and medical details of rabies, and discusses present policies in the U.K. and elsewhere for its prevention and elimination. Eight experts in different fields explain both what can be done to contain and treat rabies, and its implications for those who own or care for animals. Illustrated £1.95

The Selfish Gene

Richard Dawkins

'Richard Dawkins, one of the most brilliant of the rising generation of biologists, gently and expertly debunks some of the favourite illusions of social biology . . . learned, witty, and very well written . . . exhilaratingly good book.' Peter Medawar in *The Spectator*. 'This important book could hardly be more exciting.' *Economist*. 'We appear to have entered a new era of zoological thinking, and Richard Dawkins . . . proves himself to be an erudite, witty, and persuasive guide to the biological revolution.' *Sunday Times*. £2.95

Birds of Coast and Sea

Britain and Northern Europe

Bruce Campbell and Raymond Watson

This compact volume describes and illustrates well over eighty of the bird species most likely to be seen along the vast and varied coastline of northern Europe, from Britain to the Russian borders. Each of the sixty-four colour plates is faced by a fully comprehensive text page covering not only a careful description of the birds throughout their life cycle, but also their population, distribution, breeding habits, nests and eggs, food requirements, calls, and other identifying features. Illustrated £3.75

A.C. Motor Design

with Conventional and Converter Supplies

H. C. J. De Jong

The increasing use of electronic frequency converters in the power supply of a.c. motors leads to design problems quite different from those encountered in motors connected directly to a conventional supply. The constraints of the conventional supply lead to sealing laws for the a.c. machines connected to it, and thus to more general design rules, neither of which are valid in the converter supply situation. Other guidelines must, therefore, be sought. In this book a unified description of conventional a.c. synchronous and induction machines is given and related to the interface problems and design of converter-fed induction motors. £5 *Monographs in Electrical and Electronic Engineering*

Galaxy Formation

John Gribbin

A personal view of galaxy formation – a subject which holds a central place in modern astrophysics. The book reflects the author's own interests in this field, and thus offers a new and different perspective to a fascinating topic. Formal mathematics is kept to a minimum and the general level of the text makes it suitable for the second year physics students at university.

Contents: Stars and Galaxies-Cosmology: The Expanding Universe – The Traditional Approach· Turbulence and Gravitational Instability – Layzer's Gravitational Clustering Hypothesis – Ambartsumian's Fragmentation Hypothesis – Continual Creation – Newtonian Cosmology and Jean's Criterion – The Retarded Core Hypothesis – The Growth of Irregularities in an Expanding Universe – The Evolution of Galaxies – Our Galaxy – The Present Balance and Future Prospects.

affect basement membrane zones and the ground substance[17], and mucosal penetrability may thereby be increased.

Several possible hazards of circulating antibodies resulting from vaccination have been discussed[18]. Our results point to one way in which IgG antibodies may jeopardise mucosal integrity since undue penetration of new antigens in turn may stimulate a broader IgG response and thus set up a vicious circle. The merit of the selective glandular secretion of IgA and IgM antibodies[15] is probably to limit such a development. This must be taken into account when using vaccines in immunoprophylaxis and when the value of breast feeding is debated. In the neonatal period antigens are absorbed into the circulation in sufficient amounts to evoke a systemic IgG response in a great proportion of individuals, especially in those being artificially nourished[19]. This may predispose to untoward sensitisation of the child In addition, our results substantiate one pathogenetic potential of local IgG-cell responses in mucosal disease[14,15].

Endplate current fluctuations reveal only one channel type at frog neuromuscular junction

SIGNAL transduction between nerve and muscle is mediated by a chemical process at the neuromuscular junction In the nerve ending electrical activity causes the release of acetylcholine (ACh) into the synaptic cleft separating the nerve and muscle cells. ACh can bind to specific chemical receptors in the postjunctional muscle membrane; these receptors control a gating mechanism that can increase membrane conductance locally Normal nervous activity triggers an action potential and contraction in twitch muscle fibres. At constant membrane potential the membrane conductance change induces a current that is carried largely by Na^+ and K^+ in frog[1], moving through ACh-gated membrane channels. There has been a controversy regarding the nature of the chemically gated endplate channels, are there kinetically-independent channels for Na^+ and K^+, or are these ions transported by the same channel? Maeno[2] initially proposed separate endplate channels, arguing that the two component decay of endplate potentials in procaine-treated cells resulted from a selective effect on Na^+ channel kinetics Kordas[3,4] and Magleby and Stevens[5] argued that Maeno's two-channel hypothesis could not account for the unique reversal potential observed or the monotonic voltage dependence of endplate current (EPC) decay. The analysis below of iontophoretically-induced EPC fluctuations in procaine-treated and untreated preparations indicates that the ions which constitute the EPC are not carried by kinetically distinguishable endplate channels.

Our conclusions are based on the following quantitative description of the EPC. Consider a population of identical, independently functioning endplate channels in voltage clamp conditions at membrane potential V. When ACh is iontophoretically applied an EPC, μ_I, will flow in the open channels

$$\mu_I = \gamma P N (V - V_r) \tag{1}$$

where γ is the mean conductance of one open channel, P is the probability that any single channel will open when the endplate is exposed to ACh, N is the total number of channels, and V_r is the reversal potential at which there is no net current. The EPC will fluctuate if the application is prolonged, because individual channel lifetimes are of the order of several milliseconds[6] The fluctuations are caused by changes in the actual number of conducting channels reflecting the probabilistic nature of channel opening and closure[7] The intensity of the fluctuations may be characterised by their variance, σ^2, about the mean EPC

$$\sigma_I^2 = \gamma^2 P(1-P) N (V - V_r)^2 \tag{2}$$

Note that P is a function of ACh concentration which is non-uniform over the extended frog endplate. A more complex derivation which takes this spatial dependence into account produces essentially these same relations

If the EPC were carried in separate Na^+ and K^+ channels, similar treatment would give the mean and variance of the EPC as

$$\mu_{II} = \gamma_{Na} P_{Na} N_{Na} (V - V_{Na}) + \gamma_K P_K N_K (V - V_K) \tag{3}$$

$$\begin{aligned}\sigma_{II}^2 = {} & \gamma^2_{Na} P_{Na} (1 - P_{Na}) N_{Na} (V - V_{Na})^2 + \\ & + \gamma^2_K P_K (1 - P_K) N_K (V - V_K)^2\end{aligned} \tag{4}$$

Here the subscripted variables have meanings similar to those described above. The approximate equilibrium potentials of Na^+ and K^+ in frog muscle are $V_{Na} \simeq +40$ mV, $V_K \simeq -100$ mV. Their exact values are unimportant as long as it is noted that they clearly differ from the observed reversal potential, $V_r \simeq 0$ mV.

The two schemes may be distinguished experimentally by measuring the EPC variance at the observed reversal potential. For the single channel scheme at $V = V_r$, the net EPC is zero because the net current in each channel is zero (equation (1)); likewise the variance is zero (equation (2)). For the two-channel scheme at $V = V_r$, the net EPC is zero because the inward Na^+ current is equal but opposite to the outward K^+ current (equation (3)), however, the variance is non-zero (equation (4)) since the Na^+ and K^+ terms are each positive and cannot cancel.

EPCs were generated in voltage-clamped muscle cells of m cutaneous pectoris from the frog *Rana pipiens*. Nomarski and modulation contrast optics were used to observe the endplates, and ACh was applied by iontophoresis 10–20 μm from the cell. Normal Ringer's solution contained 100 nM tetrodotoxin whereas procaine–Ringer's did not; composition (mM). NaCl, 117.2, KCl, 2.5; $CaCl_2$, 1 8; Na_2HPO_4, 2.16; NaH_2PO_4, 0.85 (*p*H 7.0). The induced EPCs were processed by a digital laboratory computer The variance was estimated as the frequency integral of the mean spectral density of the digitised current fluctuations, taking care to exclude miniature EPCs. The methods were similar to those of Dionne and Stevens[8] and Ruff[9].

Figure 1 contains data from a cell which was not treated with local anaesthetic The mean EPC and its variance are plotted as a function of membrane potential, and it is seen that the variance approaches zero at the measured V_r. Similar observations were made on 22 untreated cells and 7 cells in 3×10^{-4} M procaine from 13 different frogs. In all cases the variance at the reversal potential was less than the uncertainty in its measurement and was typically about 2 orders of magnitude below its value at −60 mV

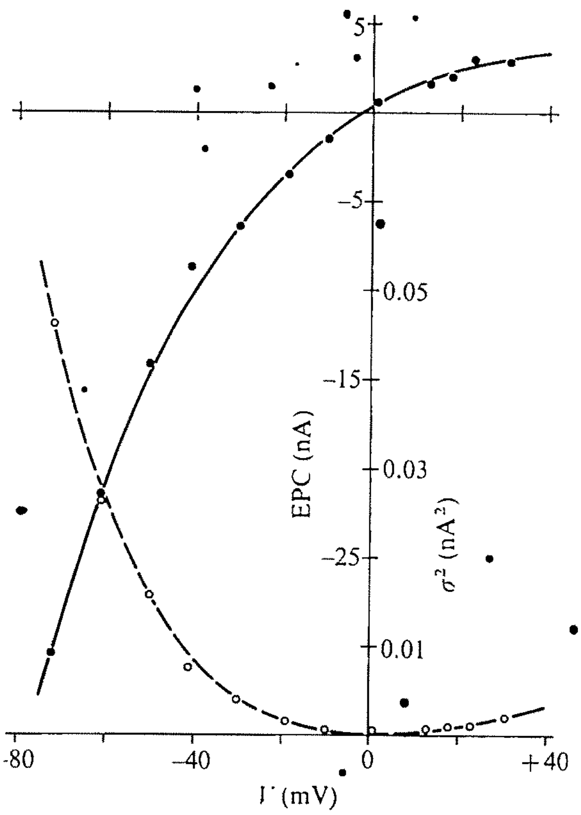

Fig. 1. Mean EPC and variance of EPC fluctuations about their mean are shown as a function of membrane potential, V. The smooth curve is equation (5) fitted to the EPC data to evaluate A, B and V_r. The values used here for the best fit are $A = -15.36\ V^{-1}$, $B = 144$ nA and $V_r = -2$ mV The same values are used to fit the voltage dependence of σ^2 with equation (6), the dashed curve The single-channel conductance at −70 mV was 22 pS for this fibre The quality of fit between theory and experiment in the variance measurements may be to some degree fortuitous Most cells exhibited slightly greater measured variance at positive membrane potentials than predicted; however, to establish a +30 mV membrane potential, holding currents of several hundred nanoamperes were commonly required Fluctuations in the holding current make accurate measurement of the few nanoampere EPC variations difficult. The data shown in this figure are from the cell with the best signal-to-noise ratio

These data are inconsistent with the model in which Na^+ and K^+ pass through separately gated endplate channels. The two-channel model predicts that the variance of the EPC is non-zero at the reversal potential. Ruff[9] also found that the variance of the EPC vanished at V_r for preparations exposed to the trimethyl lidocaine derivative QX-222, a different local anaesthetic.

The conclusion that a population of identical channels carries the EPC has been obtained by comparing measurement with theory at a single voltage, V_r. Equations (1) and (2) also provide descriptions of the functional dependence of EPC and its variance on voltage. Fitting these relations to the data, however, requires a more specific model of channel kinetics, because the probability of channel opening, P, is a function of voltage[8].

As has been shown by others[5,10,11], normal channel operations may be represented by the following kinetic scheme.

$$nT + R \overset{K}{\rightleftarrows} T_nR \underset{\alpha(V)}{\overset{\beta(V)}{\rightleftarrows}} T_nR^*$$

$$\alpha(V) = B_1 e^{A_1 V}$$

$$\beta(V) = B_2 e^{A_2 V}$$

where T represents agonist molecules, n of which bind to receptors R to produce at equilibrium an intermediate T_nR and an open channel T_nR^*. The probability of channel opening is voltage dependent, for the case here of prolonged agonist exposure, the dependence is exponential and given by[8]

$$P = \beta C^n/\alpha K$$

$$= [C^n B_2/KB_1] \exp(A_1 - A_2)V$$

where C is ACh concentration

Thus, equations (1) and (2) may be rewritten to express their voltage dependence

$$\mu_1 = B(V - V_r)e^{AV} \qquad (5)$$

$$\sigma_1^2 = \gamma B(V - V_r)^2 e^{AV} \qquad (6)$$

In writing equation (6) it has been assumed that $P \ll 1$, an approximation which is accurate in the low agonist concentration limit that applies here The voltage dependences of equations (5) and (6) are unchanged when a more detailed derivation includes the spatial non-uniformity of ACh concentration. Although equation (1) suggests that the EPC is proportional to voltage, we see in equation (5) a more complex relation as pointed out by Dionne and Stevens[8]. In addition, the variance (equation 6) is similarly affected by the voltage dependence of the probability of channel opening so that what seems to be a parabolic dependence in equation (2) is not so simple.

In Fig. 1 we have fitted equation (5) to the EPC–voltage data to evaluate A, B and V_r. These values were used in equation (6) which was drawn as the dashed curve through the variance measurements; the single-channel conductance γ was evaluated at −70 mV by taking the ratio of the ACh-induced conductance to its measured variance The skewing of σ^2 by the voltage dependence of channel gating appears as a steepening of the parabolic behaviour for $V < V_r$ and a depression at $V > V_r$, and this behaviour is well described by equation (6). The ability to predict accurately the variance from measurements of the EPC is another indication of the essential correctness of the quantitative description of receptor kinetics which we have used

Our description of endplate channel kinetics has been at two quantitative levels which contain certain basic assumptions in common. An elemental stochastic theory in which individual channels are represented as independent, two-state devices, either open or closed, leads us to conclude that Na^+ and K^+ currents at the endplate are simultaneously gated This result follows because the EPC variance at the reversal potential is zero, contrary to the predictions of models assuming separately gated ion currents. The most parsimonious implication is that both Na^+ and K^+ share the same endplate channel. It should be emphasised that our results pertain to the gating of the chemically induced conductance change and do not address the question of whether Na^+ and K^+ have equal conductance in the open channel.

Extending this simple theory by incorporating a specific kinetic scheme for receptor function has allowed us to predict the voltage dependence of the EPC variance with coefficients determined from the mean EPC The measured variance fits the predicted curve well over the range tested which supports the accuracy of the equations derived from the model. The kinetic model we used was selected because in the past it has accounted well for the general quantitative behaviour of the ACh-gated channel. Note that any kinetic scheme which yields quantitative predictions similar to ours would also be acceptable Our conclusion that individual EPC ionic species are not separately gated is independent of the particular kinetics.

It may be useful to note the quantitative behaviour of our description over a voltage range more extensive than we have been able to test. If V could have been raised above +100 mV both the mean EPC and its variance are predicted by equations (5) and (6) to fall towards zero again. This phenomenon of EPC rectification is mediated largely by channel lifetime which approaches zero as membrane potential is increased Since the dependence of channel lifetime on membrane potential is nonlinear, at positive voltages the shortened lifetime more than compensates for the increased driving potential on the current carrying ions and little or no EPC can be induced. A similar mechanism may account for anomalous K^+ rectification in voltage sensitive channels in both cardiac and skeletal muscle.

Selective activation of sympathetic ganglia in young spontaneously hypertensive rats

PROLONGED increase in peripheral sympathetic discharges producing vasoconstriction leads to enhanced synthesis of tyrosine hydroxylase (TH) and dopamine β-hydroxylase (DBH) in terminal adrenergic neurones[1,2]. This is mediated by an increased activity of the preganglionic cholinergic nerves[1]. Young spontaneously hypertensive rats (SHR) have been used as a prehypertensive model of essential hypertension to investigate whether such peripheral sympathetic neuronal activation initiates the increase of blood pressure. Study of the prehypertensive stage gives more information on the initiation of the blood pressure elevation than study of hypertensive animals. Circulating levels of noradrenaline, and DBH activity (as measures of peripheral sympathetic nerve system activity were markedly elevated in young SHR (refs 3, 4), although contradictory results were reported for adrenomedullary activity[3-7]. In young SHR, adrenal levels of DBH, TH and phenylethanolamine *N*-methyl-transferase (PNMT) activities were lowered[3], whereas other investigators[4,7] found an elevation of adrenal DBH and PNMT activities. Transection of the splanchnic nerves markedly lowered blood pressure in young[5,6] and adult SHR (refs 5, 7), and also reduced adrenal venous output of adrenaline in conscious young SHR (ref. 5). All these findings suggest enhanced activity of the adrenal medulla and preganglionic cholinergic discharges to the adrenal medulla. We report here preganglionic nerve-dependent elevation of choline acetyltransferase (ChAc) and TH activities occurring specifically in the coeliac ganglia of young SHR.

In young SHR, the activity of preganglionic cholinergic nerve input to various sympathetic ganglia, superior cervical ganglia, stellate ganglia and coeliac ganglia, and adrenal glands was examined by measuring ChAc and acetylcholinesterase (AChE) activities as a measure of presynaptic neuronal activity[8] and TH activity as an index of postsynaptic neuronal activity[9] at the age of 4–5 weeks, when the blood pressure of SHR did not differ from normotensive controls. Normotensive animals of the Kyoto Wistar rats (KWR), from which SHRs were derived, were used as controls. Systolic blood pressures as measured by a tail plethysmographic method were 105±11 mmHg (mean ± s.e.m., $n = 5$) for young KWR and 110±7 mmHg ($n=5$) for young SHR, respectively. Ganglia and adrenals were removed and homogenised in pairs in 0.2 ml of ice-cold 0.005 M Tris buffer (*p*H 7.5) containing 0.1% Triton X-100. ChAc and AChE activities[10] and TH activity[11] in the homogenates were determined radiometrically.

In young SHR, ChAc and TH activities of coeliac ganglia were signficantly elevated as compared with those in young KWR. In the superior cervical ganglia, stellate ganglia and adrenals, however, there were no significant changes (Table 1). AChE activities in all ganglia and adrenals of young SHR did not differ significantly from those of KWR. Total protein contents of a pair of coeliac ganglia in young SHR (0.44±0.03 mg, $n=5$) did not differ from those in KWR (0.41±0.02 mg, $n=5$).

Table 2 shows the effect of sectioning the pre- and postganglionic nerves to the coeliac ganglion on its elevated ChAc and TH activities, and AchE activity. Bilateral preganglionic nerve transection markedly lowered the elevated ChAc activity to a level less than the ChAc activity of KWR 5 d later, but did not change TH and AChE activities. Bilateral post-ganglionic nerve section did not change ChAc, AChE and TH activities in the coeliac ganglion. Difference in the control values for ChAc and TH in both experiments (Tables 1 and 2) may be due to sham-operated stress as well as age difference (5 or 4 weeks). Since decentralisation of sympathetic ganglia removes synaptic input to the ganglia rather than nonspecific surgical damage[12], the present finding suggests that elevated ChAc levels are due to the enhanced ACh release and formation by the activation of preganglionic neuronal input to the coeliac ganglion of young SHR. The persistent elevation of ChAc activity in the coeliac ganglion even after the post-ganglionic axotomy negated the reflex of the innervating end-organ activity. Removal of sympathetic target organs, however, is known to prevent the normal maturation of ChAc in presynaptic endings during development[13]. Selective activation of the coeliac ganglion may be explained by an enhanced reactivity of the ganglia to pre-ganglionic nerve discharges rather than the regional elevation of nerve input. After treatment with nerve growth factor, the prevertebral coeliac

Table 1 Enzyme activities in sympathetic ganglia and adrenals of young spontaneously hypertensive (SHR) and Kyoto Wistar rats (KWR) at 5 weeks of age

Organ	Choline acetyltransferase (nmol ACh per h per pair)		Acetylcholinesterase (nmol acetate per h per pair)		Tyrosine hydroxylase (nmol CO_2 per h per pair)

*$P < 0.05$ compared with KWR.

Table 2 Effects of pre- and post-ganglionic nerve transection of the bilateral coeliac ganglia on its elevated choline acetyltransferase activity in young SHR at 5 weeks of age

Group	Choline acetyltransferase (nmol ACh per h per pair)	Acetylcholinesterase (nmol acetate per h per pair)	Tyrosine hydroxylase (nmol CO_2 per h per pair)
SHR, sham operated	3.27±0.32	21.3±2.3	0.167±0.009
SHR, preganglionic axotomy	0.47±0 08*	20.7±1.4	0.152±0 011
SHR, postganglionic axotomy	2.66±0.33	19.8±1.2	0.175±0.019
KWR, sham operated	2.25±0 15†	19.5±0.8	0.134±0.011†

Values are mean ± s.e.m. for 5 animals at 4 weeks of age. Axotomy was performed under ether anaesthesia 5 d before killing. Differences in control values for ChAc and TH when compared with Table 1 are probably due to the effects of age difference and laparotomy stress.

*$P < 0.01$ compared with SHR controls.

†$P < 0\ 05$ compared with SHR controls.

ganglion shows a significantly more pronounced hypertrophy than the paravertebral superior cervical ganglion and stellate ganglion in young rats[14]. Our results indicate possible selective maturation of coeliac ganglia in young SHR. This is supported by findings that there is a rostro-caudal gradient in TH ontogeny in various sympathetic ganglia, for example, in maturation of the sixth lumbar ganglia at 2 months of age[15] and in superior cervical ganglia at 14 d (ref. 16). Thus it suggests that in the coeliac ganglia, TH activity would not reach adult plateau values by 4–5 weeks of life, the age of young SHR in our experiments.

The observed activation of the coeliac ganglion in young SHR may enhance the release of noradrenaline and DBH levels into peripheral circulation from the coeliac ganglion-innervated arteries in splanchnic region and others. It is clear that in young, prehypertensive SHR, the selective activation of pre- and post-synaptic neuronal activities in coeliac ganglia initiates the elevation of blood pressure.

Colour-coding properties of sustained and transient channels in human vision

WHEN the colour of a visual stimulus is repetitively alternated between say red and green, the percept evoked depends upon the temporal frequency of repetition At very low frequencies (for example, 1–2 Hz), the repetitive change in colour is readily apparent. But at frequencies above about 10 Hz, no changes in colour are perceived, the stimulus in this case would appear a uniform yellow but would still seem to be flickering in brightness Observations of this kind suggest that the colour of a stimulus may be analysed by a set of channels different from that analysing the brightness or flicker. The flicker or brightness channels respond to higher temporal frequencies of flicker than do the colour channels This idea was confirmed by King-Smith[1] who has described how the sensitivity to coloured flashes of light changes with flash duration He further described the subjective appearance of the flash, and concluded that a stimulus was not necessarily detected by the same channels as those that detected its colour. When the flash was brief, the stimuli usually looked achromatic, except when the wavelength was below about 490 nm The intensity of the flash had to be raised above the detection threshold before the colour could be perceived At longer flash durations, the colour was apparent as soon as the flash was detectable. The channels signalling the colour of a stimulus have a longer 'integration time' than those giving an achromatic percept. This kind of experiment examines differences in the high temporal frequency behaviour of the two sets of channels. It is of interest to examine the low temporal frequency behaviour as well because recent neurophysiological investigations of the monkey's visual system make use of this behaviour in classifying neurones[2–5]. Some neurones give a sustained response to prolonged presentation of a stationary stimulus, others respond only transiently to the stimulus onset I show here that human colour channels give sustained responses while the flicker or brightness channels give transient responses.

The stimuli were disks (1° diameter) viewed against a white background (3 5° diameter) The background, viewed through a pellicle, was made by illuminating a diffusing screen with a tungsten halide bulb of unknown colour temperature. The luminance of the background was 50 cd m^{-2} which gave a retinal illumination of about 1000 td (5 mm pupil) The light source for the 1° test stimuli was the P31 phosphor of an oscilloscope. This is not ideal as the phosphor emits little red light, so that the range of wavelengths examined is limited. Four test 'colours' were used: blue (Ilford 621; nominal peak 450 nm), green (Ilford 807; 530 nm), yellow (Ilford 626; 570 nm) and orange (Ilford 607, 590 nm). The widths of these filters at half maximum transmission are 30–80 nm.

Test stimuli were flashed on and off at intervals of 4 s while the background remained steadily illuminated. The observer adjusted the intensity of the test stimuli until he considered that they were only just visible. Eight threshold settings were made for each stimulus. In the first series of experiments, the observer attempted to detect an 8-ms flash of the stimulus superimposed on a subthreshold flash lasting 1 s. The test and subthreshold flashes were spatially co-extensive and were of the same colour. It has been argued[6] that this technique examines the subliminal response of channels to the subthreshold long flash Thus, if the subliminal response is transient, the sensitivity for the brief flash will be increased soon after the onset of the conditioning flash but will return to its control value after 100–200 ms, as the transient response subsides. But, if the subliminal response is sustained, the sensitivity will not return to its control value until after the end of the conditioning flash.

Figure 1*a* illustrates the results of such an experiment for three different colours. In all three cases the sensitivity to the test flash was increased when it appeared 16 ms after the onset of the conditioning flash. For green and orange stimuli, the sensitivity returned almost to normal when the test flash appeared 500 ms after the onset of the conditioning flash The subliminal response to the long flash was transient. For the blue flash, however, the sensitivity remained high, suggesting a sustained subliminal response

In confirmation of King-Smith's finding, the brief green and orange flashes appeared almost achromatic while the blue flash did appear a deep blue. The almost achromatic percept was of a silvery glow with perhaps a tint of the appropriate colour No attempt was made to show rigorously that the percepts evoked by the green and orange stimuli were indistinguishable.

Figure 1*c* shows the results of a similar experiment, but with test flashes lasting 250 ms. For both the green and orange stimuli, the sensitivity to the test flash remained higher than normal even when it was presented 500 ms after the onset of the long flash. The subliminal responses of the channels detecting the 250-ms flashes were sustained. Again, confirming King-Smith's observations, the test flashes (being long) appeared coloured.

These results suggest that if a narrow-band stimulus appears coloured, it is detected by sustained channels. If it seems achromatic, it is detected by transient channels. It might be expected that, if two stimuli seem to be of different colours, they would be detected by channels responding to different narrow bands of wavelength, the stimuli might be detected independently. Apparently-achromatic stimuli of different wavelength might be detected by one set of broad band channels, stimuli of different wavelength would summate.

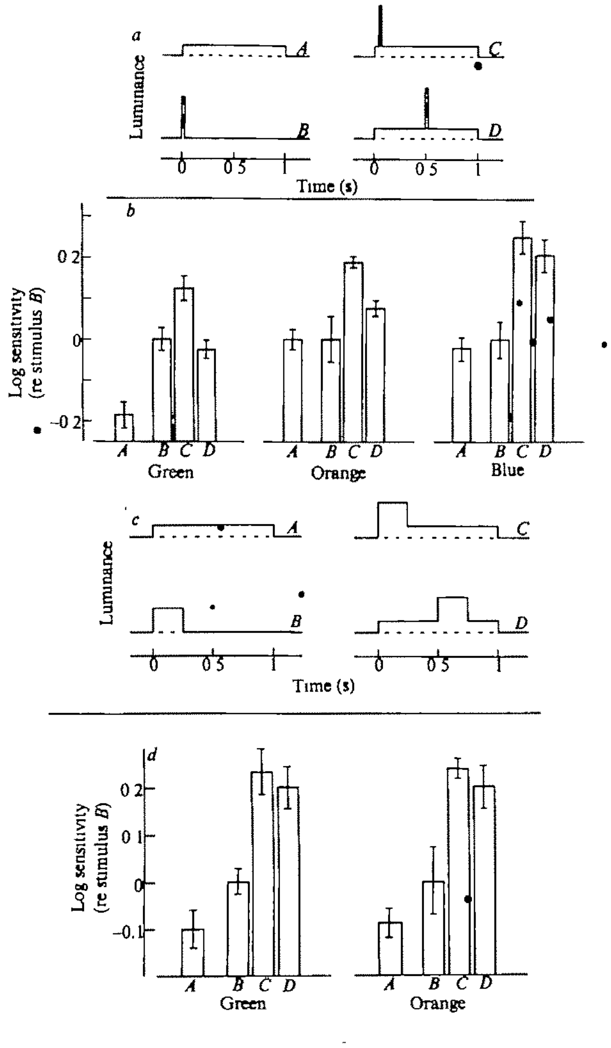

Fig. 1 Sensitivity to an 8-ms flash in the presence of a subthreshold flash lasting 1 s. *a*, Temporal waveforms of the four stimuli. Stimulus *A* is the conditioning flash alone, stimulus *B* is the test flash alone. In stimulus *C*, the test flash occurs 16 ms after the onset of the conditioning flash, in stimulus *D*, the test flash occurs with a delay of 500 ms. *b*, Sensitivities for the four temporal waveforms, for each of three colours. Sensitivity (mean) is expressed relative to that for stimulus *B* in each case. The vertical lines on each histogram block show ± 1 s.e.m. *c* and *d* are as for (*a*) and (*b*), respectively, except that the test stimuli lasted 250 ms as shown in the upper panel. Only green and orange stimuli were used.

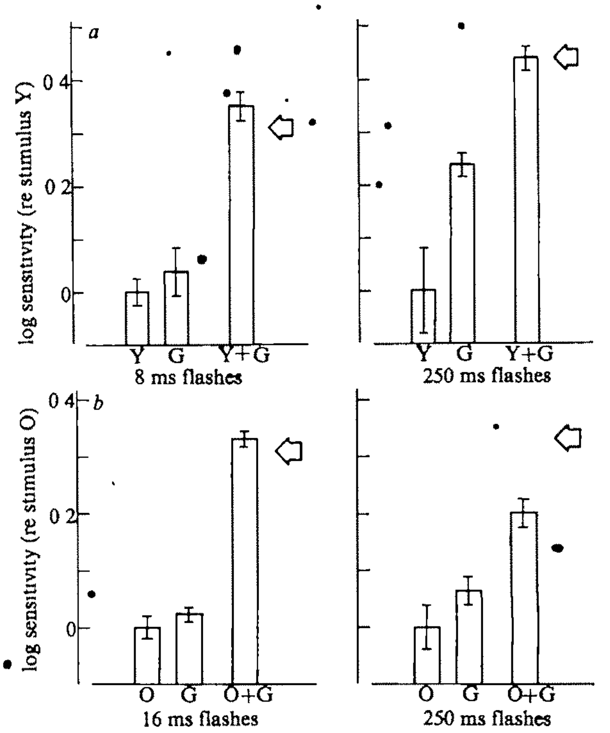

Fig. 2 Summation between stimuli with different wavelength composition *a*, for yellow (Y) and green (G) stimuli. Summation was examined at two flash durations. The yellow and green flashes in each case were synchronous and of the same duration. Sensitivity is expressed relative to that for the yellow stimulus alone. The horizontal arrows show the sensitivity for the composite stimulus if there had been perfect summation of the sensitivities to the two components *b*, for orange (O) and green (G) stimuli.

Figure 2*a* illustrates an experiment to test this prediction. Two test stimuli of different colour were generated using two oscilloscopes viewed through a half-silvered mirror. In the upper part of the figure, a yellow flash was added to a simultaneous green flash. The relative intensities of the two stimuli were adjusted to make them more or less equally detectable alone. The sensitivity to the mixture was then determined. The arrows show the sensitivity that would have been achieved if there had been perfect summation. Both for short and for long flashes, summation was more or less perfect, implying that the two colours were detected by the same channels. This was found even though the long flashes appeared coloured. The green and yellow flashes were not easily distinguishable, however, both appeared to be green at threshold, suggesting that they were detected by the same colour-signalling channels. Figure 2*b* shows a similar experiment. The wavelengths of the two test stimuli were made more dissimilar (green and orange). Perfect summation was found only for the brief flashes, when both stimuli appeared achromatic. At long durations, the flashes appeared to be of different colours, and summation was incomplete. These results seem to be consistent with the observation that summation of the brightness of different wavelengths is almost perfect in flicker photometry[7], whereas complex interactions are found when the stimuli are presented for 500 ms (ref. 8).

My results confirm King-Smith's suggestion that there are two sets of channel in the human visual system. One class signals the colour of a stimulus, this class is made up of several subsets, which each respond to a limited band of wavelengths. The second class of channel does not give information about the colour of a stimulus, but responds to a broad band of wavelengths. This paper has added the observation that the colour-coded channels give sustained responses to flashed stimuli, while the broad-band channels give transient responses at the onset of the flash. Single neurones in the monkey visual system show a similar difference: colour-opponent neurones give sustained responses, whereas broad-band non-opponent neurones respond transiently[2–5]

Solubilisation and partial purification of auxin-binding sites of corn membranes

THE demonstration by Hertel *et al.*[1] of reversible, high-affinity binding of auxins to membranous preparations from corn coleoptiles provided for the first time a reliable and readily accessible system for the study of potential receptor–phytohormone interactions. In a detailed investigation of the binding kinetics and specificity of this system, we presented evidence for the presence of two classes of auxin-binding sites with differing affinities and specificities[2,3]. Site 1, with a K_D for the synthetic auxin 1-naphthalene-acetic acid (NAA) of 0.14 μM, was able to bind both auxins and physiologically inactive analogues, whereas site (K_D for NAA = 1.7 μM) displayed binding specificity compatible with that expected of an auxin receptor[2] and was located in a heavier membrane population, enriched in plasma membrane[3]. Auxin-binding activity can be readily solubilised from the membranes with Triton X-100 (ref. 2), but our attempts to purify such extracts further have met with only limited success. I report here that both binding sites can be conveniently removed from the membranes without detergent and purified approximately 100-fold in two steps.

Membranes were prepared from 40–80 g of corn coleoptiles (*Zea mays*, Kelvedon 33) by differential centrifugation between 4,000*g* and 80,000*g*, as before[2]. The pellets were suspended using a Teflon–glass homogeniser, in 0.1 volume (based on original tissue weight) of grinding buffer[2] and the suspension was added to 20 times its volume of Analar acetone at 4 °C, with stirring. The clumped precipitate was separated from the yellow, opalescent supernatant by vacuum filtration or by low-speed centrifugation, washed with acetone and dried in a stream of nitrogen. The dried residue was extracted by homogenisation in DBB (a fivefold dilution of binding buffer, see Fig. 1 legend and ref. 2) and insoluble material was removed by centrifugation at 38,000*g*, 15 min.

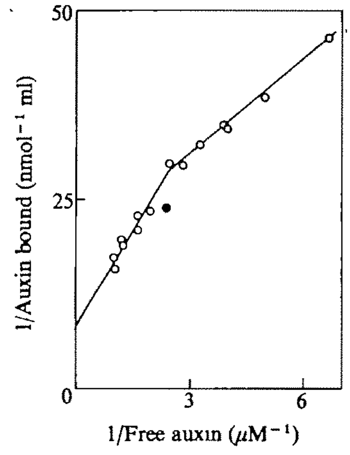

Fig. 1 Double reciprocal analysis of NAA binding to the crude membrane extract Samples of 1 ml (each equivalent to 2 g of tissue) were dialysed against 1 ml of ^{14}C-NAA (61 mCi mmol^{-1}, Radiochemical Centre, Amersham) in binding buffer (0 25 M sucrose, 5 mM $MgSO_4$, 10 mM citrate–acetate, *p*H 5 5), supplemented with varying amounts of unlabelled NAA to give a range of equilibrium concentrations from 0 15 to 1.0 μM. Equilibrium required a minimum of 5-h dialysis at 4 °C using Dianorm cells (MSE, Crawley) Radioactivity in 750-μl aliquots from each half-cell was determined by liquid scintillation counting The regression lines of the double reciprocal plot were fitted by the method of Wilkinson[4]; site binding constants were derived as described by Hunston[5] for a two-site system $K_1 = 0\ 17\ \mu M$, $n_1 = 14\ 3$ pmol g^{-1}; $K_2 = 1.4\ \mu M$, $n_2 = 51$ pmol g^{-1}.

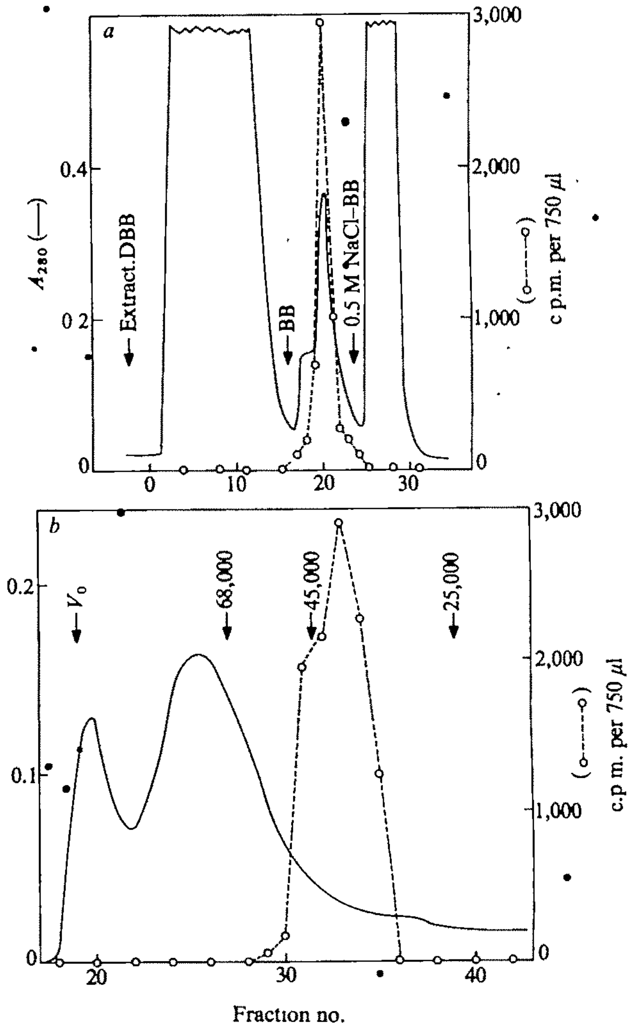

Fig. 2 Purification of auxin-binding proteins. The crude membrane extract was applied to a 5 × 1 5-cm column of DEAE Bio-Gel (Bio-Rad) equilibrated in DBB (fivefold diluted binding buffer; see legend to Fig 1) The column was washed with DBB until A_{280} approached the baseline value Elution was then continued step-wise with binding buffer (BB), followed by 0.5 M NaCl in binding buffer Fractions of 2.5 ml were collected and aliquots (diluted to 1 ml with binding buffer) were assayed for auxin binding by equilibrium dialysis against 1 ml of 0.3 μM ^{14}C-NAA Binding was determined from the radioactivity difference between each pair of half-cells The fractions with binding activity were pooled, concentrated to 1.8 ml by centrifugal ultrafiltration (Amicon CF25 membrane cones) and applied to a column, 81 × 1 5 cm of Sephadex G100 (Pharmacia), equilibrated in binding buffer Fractions of 2 0 ml were collected and assayed for auxin binding *a*, DEAE Bio-Gel profile, *b*, Sephadex G100 profile V_0, void volume (ferritin). Arrows indicate elution peaks of standard proteins of the molecular weights indicated. ———, Absorbance at 280 nm, — — —, ^{14}C-NAA binding

Binding of ^{14}C-NAA to these crude membrane extracts was examined by equilibrium dialysis Double reciprocal analysis (1/bound against 1/free) of the binding data yields biphasic plots (Fig. 1) similar to those obtained with intact membrane preparations[2], and suggesting that both sets of binding sites have been solubilised from the membranes. The dissociation constants ($K_1 = 0.17\ \mu M$; $K_2 = 1\ 4\ \mu M$) and the proportionality of binding sites ($n_1 : n_2$) are in good agreement with the values for site 1 and site 2 respectively deduced in earlier membrane experiments[2] The total yield of soluble binding sites in different experiments has ranged from 45 to 90% of that expected in the original membranes, the source of this variability is not clear

When the buffer extracts were fractionated on DEAE Bio-Gel, auxin-binding activity was confined to the peak eluted with binding buffer (Fig. 2*a*) The auxin-binding material is heat labile (>90% loss of activity after 5 min at 90 °C), non-dialysable, and precipitates at 70% ammonium sulphate saturation. The post-DEAE binding fractions are positive to the Lowry reagent[6] and nucleic acids were undetectable by organic micro-phosphorus analysis[7] The binding species are therefore likely to be proteins The pooled post-DEAE binding fraction was further purified on Sephadex G100, yielding a single, usually asymmetrical auxin-binding peak (Fig.2*b*). The apparent molecular weight at the shoulder (fraction 31) is 47,300 and at the peak (fraction 33), 40,300 Overall purification in the two-column steps on the basis of c p m. bound per mg protein (mean of three experiments) is approximately 100-fold (crude extract = 1750, DEAE peak = 14,500, G100 peak = 171,800).

The asymmetric nature of the binding profile from Sephadex G100 could indicate a partial resolution of site 1 and site 2 proteins Gel electrophoretic analysis of the post-Sephadex binding fractions indicates only limited heterogeneity, but additional purification and scaling-up are needed to assign the binding protein bands with greater confidence. Investigation of the effects of potential affinity labels on auxin binding to isolated corn membranes has permitted the tentative assignment of several of the amino acid residues in the binding site environment[8]. The availability of the solubilised binding proteins and the use of radioactive affinity labels will facilitate further characterisation of the binding sites

The problem of establishing directly the significance of the binding sites in relation to the physiology of auxin action is more difficult to approach, but in principle it should be possible to incorporate the binding proteins in a synthetic membrane system, perhaps in conjunction with an ATPase, and look for a specifically auxin-mediated response such as proton pumping[9]

I thank Richard Bumpus for technical assistance

Relationship between amount of Epstein–Barr virus-determined nuclear antigen per cell and number of EBV–DNA copies per cell

EPSTEIN–BARR virus-determined nuclear antigen (EBNA) can be detected in all EBV-DNA-carrying cells[1,2]. This includes Burkitt's lymphoma (BL) and nasopharyngeal carcinoma (NPC) tumour biopsy cells' and EBV-carrying lymphoid lines[1-5] Of the known EBV-associated antigens only EBNA is regularly associated with the presence of viral genetic material, no matter whether the cell line produces virus or not[6,7]. The composition and function of EBNA are largely unknown. Some recent reports suggest that EBNA is a protein that binds to DNA *in vitro*[8,9], and is associated with chromosomes *in vivo* at least in part[1]. EBNA might be a virally determined or virally altered chromosomal protein of the non-histone type[9] It is tempting to speculate that EBNA has a role in EBV-induced cell transformation ("immortalisation"[10]) and/or in the control of viral gene expression There is a wide variation in the average number of EBV genome equivalents between different EBV–DNA-carrying cell lines. In virus non-producer cell lines this number is a better approximation of the true EBV genome number for individual cells than in virus producer lines, and is relatively stable over long periods of serial passage[11] The EBNA content of EBV-containing cell lines also seems to vary between different cell lines, as judged visually in the fluorescence microscope We have measured the amount of EBNA per cell, by quantitative immunofluorimetry in different cell lines, in parallel with determining the average number of EBV–DNA copies, and established a correlation between these two parameters.

Eleven non-producer lines were tested Three were derived from Burkitt's lymphoma (Raji[12], Namalwa[13], Rael[11]), three were independently established somatic cell hybrids of Raji and Namalwa (RN2, RN17, RN21) (ref. 15), four were EBV-carrying lymphoblastoid cell lines of non-neoplastic origin (303L (ref. 16), 6410 (ref. 17), F265 (ref. 18), PESS (ref. 14) and one was an EBV-converted derivative of the EBV-negative BL line Ramos (AW-Ramos (ref 19)). The average number of EBV genome equivalents per cell was estimated by nucleic acid hybridisation as described previously[3]. Briefly, 10-μg aliquots of cellular DNA, immobilised on nitrocellulose filters, were incubated for 96 h at 45 °C with 1 ng (1.5×10^5 c.p.m.) ^{32}P-labelled EBV complementary RNA (cRNA) in 0.3 ml 0.9 M NaCl–0 09 M trisodium citrate, containing 50% formamide Negative (calf thymus DNA) and positive (NC37 (ref. 18) cellular DNA) controls were included in all experiments. The number of EBV genome equivalents per cell were calculated from the assumption that the molecular weight of EBV DNA is 10^8 (ref. 20), that of DNA from a diploid human cell 4×10^{12}, and that of DNA from a tetraploid cell 8×10^{12}.

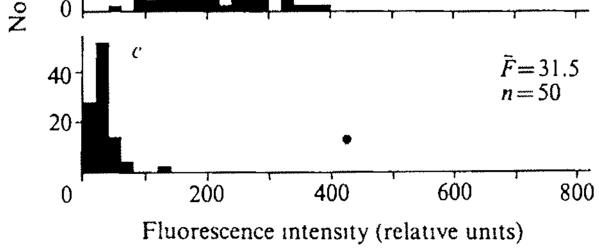

Fig. 1 Frequency distribution of EBNA fluorescence intensities of individual cells in cell lines that carry on average 160 (RN17, *a*), 60 (Raji, *b*) and 3 (Namalwa, *c*) EBV genome equivalents per cell

For immunofluorimetry, small circles were drawn on a slide with a diamond. Cells of different cell lines were placed within different circles and diluted to allow a distance of 2–3 cell diameters between individual cells, in order to facilitate individual cell measurement without neighbour interference. Two

Raji cell samples were placed on each slide for reference. The cell patches were dried, fixed in acetone–methanol (2:1) for 3 min and incubated with an EBNA-positive serum from a BL patient (M.A., Kenya Cancer Council No. 1530, EBNA titre 1:160, VCA titre 1:640 and EA-R titre 1:40, diluted 1:10 with BSS) for 30 min. Thereafter the slides were incubated for 30 min with 1:10 diluted complement from a healthy human donor (I.E.) with no antibodies to EBNA or to any other EBV-determined antigens. Staining was carried out using fluorescein-labelled goat anti-human β_{1c} (Hyland laboratories, Los Angeles, California). Fluorescence emission of randomly selected individual cells was determined by microspectrofluorimetry as described previously[21].

Figure 1 shows the frequency distribution of fluorescence intensity (FI) per cell in three lines. Raji and Namalwa were compared with one of their somatic hybrid derivatives, RN17 In each line fluorescence intensity per cell is distributed over a wide range. It is noteworthy that the FI values of the RN17 hybrid were not only higher than for either parent, but exceeded for most cells the additive value of the two parental lines.

EBNA fluorescence intensities of the same cell line (Raji) varied considerably between different experiments. To standardise the system, the mean value of the Raji cell patch on each slide was taken as reference value for the other lines measured on the same slide. This was chosen as a reference because the variation between Raji patches on the same slide was much smaller than between different slides and different experiments. Following this procedure the EBNA content of the different cell lines could be compared and studied in relation to the number of EBV genome equivalents per cell. As shown in Fig. 2, there was a strong correlation between these two parameters (*r* — 0.86). Three lines, Namalwa, 6410 and AW-Ramos, had low numbers of EBV genome equivalents per cell and they also had the lowest quantity of EBNA per cell. Four lines, 303L, F265, PESS, and Raji, had intermediate EBNA and EBV–DNA values. The three RN hybrids confirmed the impression gained from Fig. 1, in showing that the amount of EBNA per cell was not simply an addition of the parental values, but was amplified beyond the expected sum of the parents Even more interesting was the fact that this amplification seemed to be directly proportional to the amplified EBV genome copy number, already demonstrated by Andersson[11] One cell line shows comparably low fluorescence intensity, Rael. It had a very low EBNA value per cell, but a somewhat higher EBV–DNA copy number than expected. In this context it is interesting to note that Brown *et al*[22]. found that the binding of radiolabelled anti-EBNA antibodies to Raji nuclei was completely inhibited by nuclear extracts from several EBNA-positive cell lines, but only partially inhibited by Rael extracts. This suggests that Rael might lack some antigenic subcomponent of EBNA. This would also explain the low fluorescence intensity of Rael cells.

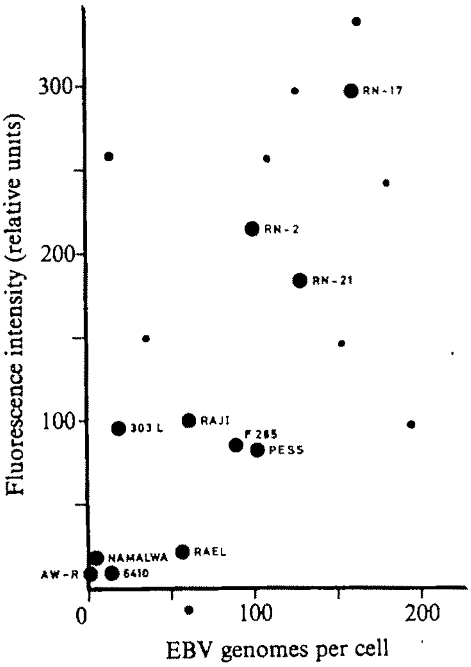

Fig. 2 Amount of EBNA per cell (mean cellular fluorescence intensity) plotted against average number of EBV genomes Mean EBNA fluorescence value of each Raji standard cell population has been normalised to 100. All individual cell values of the other lines were computed in relation to the reference value. The corrected mean values were entered for each cell line. These mean values are based on the following number of cells measured: Raji 358, AW-Ramos 162, Namalwa 143, PESS 56, F265 15, 6410 40, Rael 25, 303L 13, RN-2 40, RN-17 40, and RN-21 40. The number of EBV genomes was estimated by filter nucleic acid hybridisation as described in the text.

Obviously, the calculation of mean EBV–DNA and EBNA values masks the previously demonstrated cycle-dependent variation of both parameters[23] (also I.E. and D.K., unpublished). The multiple EBV genomes carried in non-producer Raji cells were shown to replicate during early S phase[23]. We have found that EBNA increases continuously during the cell cycle, most of the increase occurring during the G1 phase (I.E. and D.K., unpublished). The fact that the mean values show a strong correlation suggests that physiological variations tend to 'even out' in large populations sampled on different occasions

The relationship between mean EBV–DNA and EBNA values raises some intriguing questions. It is known that the 'immortalising', proliferative interaction of EBV with its host cell, the human or primate B lymphocyte, is entirely dependent on the restrictions of viral gene expression that prevent the entry of EBV-DNA-carrying cells into the invariably lethal viral cycle. Non-histone chromosomal proteins are believed to have a transcription-regulating role in differentiated cells[24,25]. Since EBNA seems to be a virally induced or virally changed chromosomal protein, it is tempting to speculate that it may have an analogous role, perhaps in direct relation to the EBV cycle. A positive correlation might be expected between EBNA and EBV–DNA if EBNA regulates the transcription of the multiple viral genomes. Alternatively, or in addition, EBNA may have a role in transforming the normal B lymphocyte into an indefinitely proliferating, established cell line. As a third possibility EBNA might be simply a product of the latent viral genomes, without having any role in viral transformation or in the maintenance of viral latency. The correlation we have found might then be due to a viral gene-dosage effect.

Proton pump coupled to cytochrome *c* oxidase in mitochondria

CYTOCHROME *c* oxidase is an important enzyme of aerobic metabolism, catalysing electron transport between cytochrome *c* and molecular oxygen. Apart from this essential redox reaction the enzyme must be involved in conservation of the released redox energy for utilisation in ATP synthesis at the socalled third site of oxidative phosphorylation. I report here that the redox activity of mitochondrial cytochrome *c* oxidase is coupled to the translocation of hydrogen ions across the inner mitochondrial membrane This finding may be a clue to the role of cytochrome oxidase in energy conservation.

Cytochrome oxidase is located in the inner mitochondrial membrane, as are the other components of the respiratory chain and the ATP synthetase complex. Moreover, the enzyme seems to span the membrane, being exposed to some extent on both surfaces[1] Mitchell's chemiosmotic hypothesis of oxidative phosphorylation[2–4] postulates that cytochrome oxidase catalyses transmembrane electron transfer from cytochrome *c* (on the outside) to oxygen, which is reduced on the inside of the membrane with consumption of H^+ ions The vectorial electron transfer is suggested to give rise to a membrane potential ($\Delta\psi$) while the inside H^+ consumption gives rise to a *p*H gradient (ΔpH). The resulting electrochemical proton gradient (or protonmotive force, $\Delta\mu_{H^+} = \Delta\psi - 60\Delta p\mathrm{H}$) is suggested to be the driving force for oxidative phosphorylation[2–4].

The conformation of the haems in mitochondrial cytochrome oxidase changes in parallel to $\Delta\mu_{H^+}$, but does not correlate with either of its components, $\Delta\psi$ or ΔpH, alone[5]. Energisation of mitochondria, which is associated with the development of a protonmotive force of some 200 mV (positive outside)[6], shifts the enzyme into a more low-spin conformation with associated changes in spectral, redox and kinetic properties[5,7–11]

The parallelism between the electrochemical proton gradient and the conformation of cytochrome oxidase is demonstrated in Fig. 1, where a diffusion potential of potassium ions is specifically induced across the mitochondrial membrane with the aid of the ionophore valinomycin. As demonstrated previously[12], the electrical potential difference can be monitored spectrophotometrically using safranine as a probe, while ΔpH can be recorded by means of the *p*H indicator neutral red[13]. As Fig. 1 shows, the electrical diffusion potential decays slowly, as expected, from a membrane system orders of magnitude less permeable to ionic species other than potassium. Neutral red shows progressively more acidity inside the mitochondria, with kinetics lagging behind the formation of the electrical potential. This suggests a relatively slow flux of protons into the mitochondria in response to the induced membrane potential. The spectral shift in ferric cytochrome oxidase (see refs 5,7–10) develops with kinetics similar to the safranine signal, but decays with much faster kinetics, similar to those of neutral red. Thus the conformation of cytochrome oxidase follows neither the $\Delta\psi$ nor the ΔpH component of the protonmotive force, but seems to change in parallel with their sum ($\Delta\mu_{H^+}$), decaying as the protonmotive force decays primarily due to increased internal acidity.

Cytochrome oxidase would be expected to be sensitive to the electrochemical proton gradient if the conformational change of the enzyme were coupled to the translocation of hydrogen ions across the membrane. Thus $\Delta\mu_{H^+}$ may drive protons into the mitochondria through a 'pump' coupled to the high- to low-spin transition in ferric haem Conversely, and more important, redox activity of cytochrome oxidase may lead to the low-spin 'high energy' form of the enzyme, followed by transition to high-spin coupled to translocation of H^+ ions out across the membrane[14]

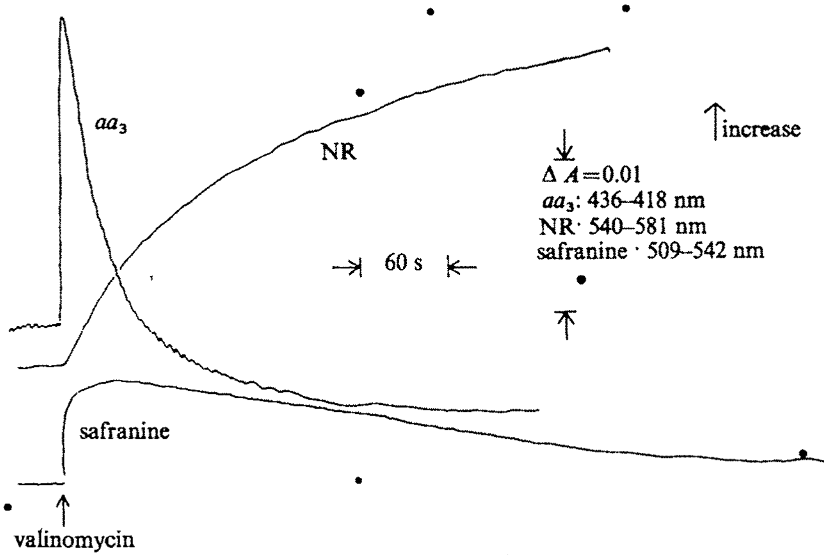

Fig. 1 Kinetics of membrane potential, *p*H gradient and spectral shift in ferric cytochrome *c* oxidase The reaction mixture contained 0.2 M sucrose and 30 mM HEPES buffer, *p*H 7.2, with further additions of 10 μM rotenone, 0.33 mM EDTA, 0.9 mM sodium ferricyanide, oligomycin (9 μg ml^{-1}) and rat-liver mitochondria (3.6 mg protein per ml) In the experiment marked NR, a further 45 μM of neutral red was added, and in the experiment marked safranine, this dye was added to a concentration of 20 μM Dual wavelength spectrophotometry was performed at the indicated wavelength couples, using cuvettes with 1.0-cm light path Temperature was 23 °C Each experiment was started after 30 s pre-incubation with the mitochondria, by addition of valinomycin (0.1 μg ml^{-1}). An upward deflection of the safranine trace indicates formation of an electrical membrane potential with positive polarity extramitochondrially[12] An upward deflection of the NR trace indicates acidification of the intramitochondrial space[13] (at the high extramitochondrial buffering power used the dye measures intramitochondrial *p*H only[13]) Upward deflection of the trace marked aa_3 signifies the energy-linked spectral shift in the ferric cytochrome *c* oxidase[5,8–10]

This possibility was tested by pulsing aerobic mitochondria with

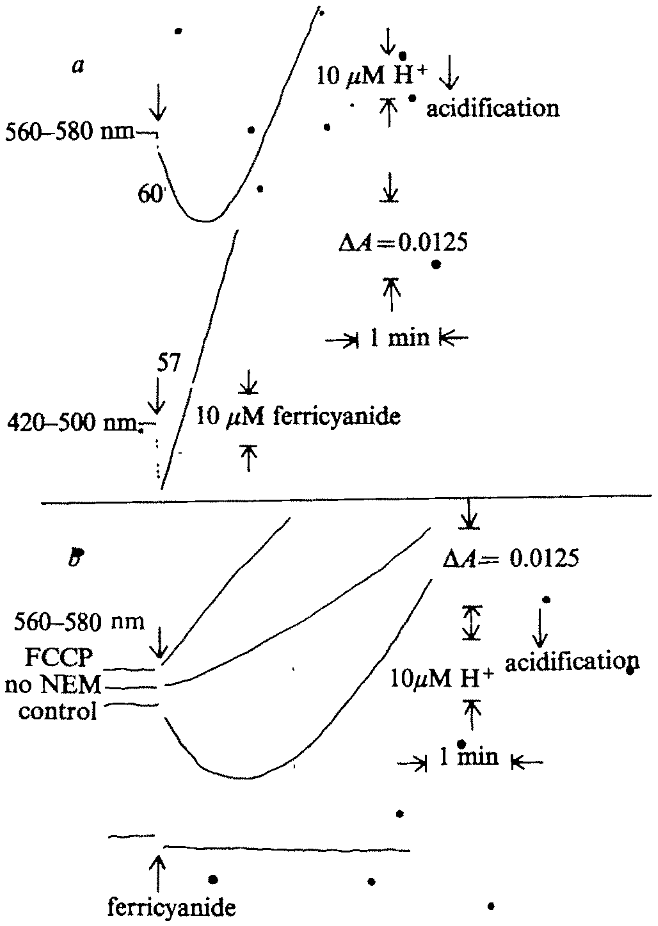

Fig. 2 Ejection of hydrogen ions coupled to oxidation of ferrocyanide in mitochondria. The reaction medium, 0.15 M KCl–1 mM HEPES, *p*H 7.4, was supplemented with 10 μM rotenone, antimycin (0.21 μg ml^{-1}), valinomycin (0.67 μg ml^{-1}), oligomycin (6.7 μg ml^{-1}), 0.67 mM EDTA, 0.33 mM NEM and rat-liver mitochondria[20] to a final concentration of 5.3 (*a*) or 6.0 (*b*) mg protein per ml. A dual wavelength spectrophotometer (Johnson Research Foundation Workshops, Philadelphia) was used at the wavelength couples indicated. An increase in the absorption difference results in an upward deflection of the trace. Light path was 1.0 cm and temperature was 23 °C. Recording of extramitochondrial *p*H (*a*, upper trace, and *b*) was done in the presence of 10 μM phenol red. The signal was calibrated with aliquots of HCl and found to be linear with (H$^+$) in the range measured. Ferricyanide production (*a*, lower trace) was recorded in the absence of the *p*H indicator. The signal was calibrated with known concentrations of ferricyanide. The reaction was started after 10 min preincubation by addition of 0.67 mM (*a*) or 0.33 mM (*b*, upper traces) ferrocyanide (at arrow). For the lower trace of (*b*), 0.67 mM ferricyanide was added as a control. Numbers adjacent to traces in (*a*) refer to initial rates in μM min^{-1} of H$^+$ production (upper trace) and ferricyanide formation (lower trace) respectively. In (*b*) 0.8 μM carbonylcyanide *p*-trifluoromethoxyphenylhydrazone (FCCP) was present when indicated.

ferrocyanide as electron donor. The mitochondria were pretreated with rotenone and antimycin to minimise endogenous respiration, and oligomycin to abolish any proton influx linked to phosphorylation of endogenous ADP. The experiments were performed in a KCl medium with valinomycin to ensure that any electrogenic proton efflux would be balanced electrically by influx of potassium ions. *N*-ethyl-maleimide (NEM) was further added to inhibit the proton–phosphate symporter (or hydroxyl–phosphate antiporter) of the mitochondrial membrane[15].

In these conditions oxidation of ferrocyanide by oxygen through cytochrome *c* and cytochrome oxidase indeed resulted in net release of protons into the extramitochondrial phase (Fig. 2*a*). The stoichiometry of the initial phase of the reaction was very closely one H$^+$ ion released per oxidised ferrocyanide, with ferrocyanide pulses between 0.13 and 1.35 mM. After the initial proton release there is alkalinisation of the mitochondrial suspension (Fig. 2) due to consumption of protons in the reduction of O$_2$ to water. In the presence of a proton-conducting uncoupling agent (FCCP, Fig. 2*b*), only the latter H$^+$ consumption is observed with the expected H$^+$/e$^-$ stoichiometry of 1.0. Fig. 2*b* also shows that inhibition of the proton–phosphate symporter by NEM is a prerequisite for observation of net H$^+$ ejection. Leaving out either the valinomycin or the oligomycin retarded net H$^+$ release (not shown). The lack of these constituents in the ferrocyanide pulse experiments of Mitchell and Moyle[16] may explain why they did not observe proton release. That the H$^+$ ejection is indeed coupled to oxidation of ferrocyanide and not to reduction of formed ferricyanide by endogenous substrates (though rotenone and antimycin were present to prevent this) was confirmed by the finding that ferricyanide itself produced negligible H$^+$ ejection (Fig. 2*b*). Moreover, inhibition of cytochrome oxidase by cyanide was fully inhibitory. Appropriate controls ensured that true *p*H changes were measured by the phenol red technique. Identical experiments using a *p*H electrode instead of the dye (not shown) confirmed that this was indeed the case.

It seems likely that the protons ejected into the extramitochondrial space originate in the mitochondrial matrix rather than in membrane protein components, for with large ferrocyanide pulses the number of protons ejected exceeds the content of respiratory chain complexes by a factor larger than 25. Moreover, with neutral red as an indicator of intramitochondrial *p*H (ref 13) a ferrocyanide pulse caused rapid alkalinisation (Fig. 3), which was highly inhibited by uncoupling agents, and the extent of which was enhanced by NEM.

These results suggest that the oxidation of ferrocytochrome *c* by oxygen as catalysed by mitochondrial cytochrome *c* oxidase is coupled to the activity of an electrogenic proton pump. The H$^+$ translocation is apparently linked to a conformational change in cytochrome *aa*$_3$ with an associated spin state transition in the haem structure. The basic mechanism thus resembles the Bohr effect in haemoglobin[17] though in cytochrome oxidase the protons are translocated across a membrane with conservation of energy. The

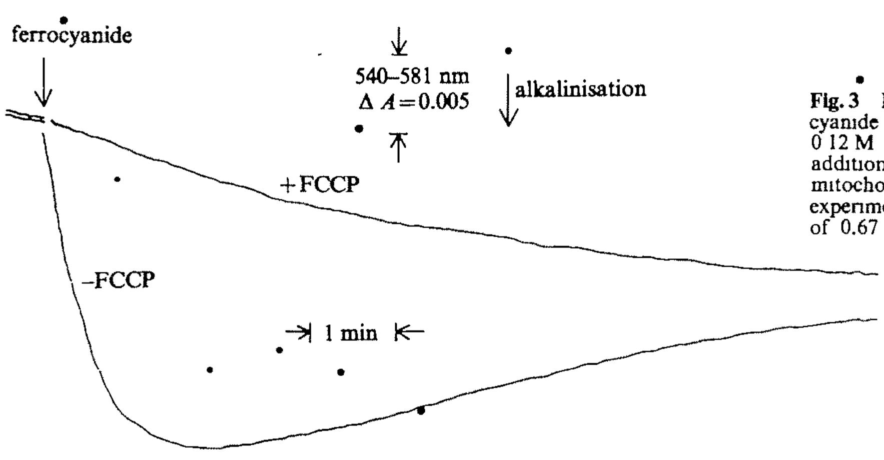

Fig. 3 Intramitochondrial alkalinisation coupled to ferrocyanide oxidation by mitochondria. Reaction mixture 0.12 M KCl–30 mM HEPES-Tris buffer, *p*H 7.4 with additions as listed in the legend to Fig. 2. Rat-liver mitochondria 5.2 mg protein ml^{-1}. Neutral Red 67 μM. The experiment was performed as described in Fig. 1, by addition of 0.67 mM ferrocyanide in the absence (−FCCP) or presence (+FCCP) of 0.8 μM FCCP.

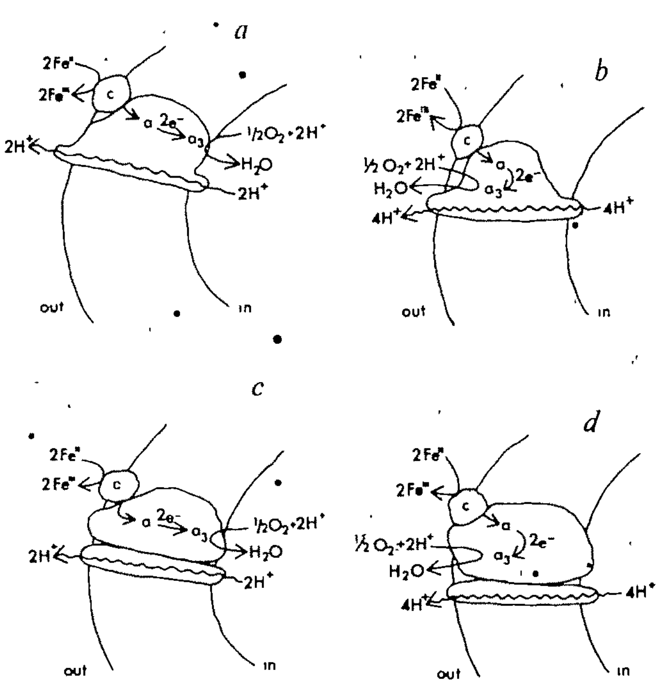

Fig. 4 Possible arrangements of the proton pump coupled to mitochondrial cytochrome c oxidase Symbols c, a and a_3 indicate the respective cytochromes, Fe^{II} and Fe^{III} indicate ferro-and ferricyanide respectively. For further details, see text.

observed H^+/e^- stoichiometry of 1 means that transfer of two electrons to $1/2\ O_2$ leads to separation of four charges across the mitochondrial membrane and not two as envisaged in the chemiosmotic hypothesis[18] As shown in Fig. 4, however, there are at least four possible arrangements of cytochrome oxidase and the proton pump in the mitochondrial membrane. Alternatives *a* and *c* retain the transmembrane electron transfer feature of cytochrome oxidase[4] but add a proton pump with a stoichiometry of 1 H^+/e^- either as part of (the subunit structure of) the enzyme itself (*a*), or as a separate molecular entity (*c*). If electron transfer is not electrogenic (*b* and *d*), the proton pump must be responsible for the entire charge separation and should thus operate with a stoichiometry of $2H^+/e^-$ (or $4H^+/2e^-$) to fit the present data Distinction between alternatives *a* and *b* compared with *c* and *d* should be possible by studying H^+ translocation in liposomes incorporated with purified cytochrome oxidase[19] Studies of this kind have shown (my and H T. Saari's unpublished work) that the proton pump described is an intrinsic property of this enzyme (*a* and *b*, Fig 4) rather than a separate molecular entity (*c* and *d*, Fig 4). A distinction between alternatives *a* and *c* compared with *b* and *d* may, however, be more difficult experimentally.

I thank Mrs Marja-Liisa Carlson for technical assistance, Mrs Tuire Wikstrom for drawing the figures and Mrs Sirkka Rönnholm for typing the manuscript. This work was supported by a grant from the Sigrid Jusélius Foundation, Helsinki

Non-allelic variants of histones 2a, 2b and 3 in mammals

THE genome of eukaryotes is organised in nucleoprotein fibres formed by the interaction of the DNA with small basic proteins, the histones, and by specific interactions between certain histones[1] To gain more insight into the molecular organisation of chromosomes it is necessary to determine in detail the complexity and variability of the histones. The chromosomes of eukaryotes contain five major types of histones. One of these, the very lysine-rich H1, consists of a small number of polypeptides which differ slightly in primary structure and which are present in different relative amounts in different tissues[2]. The other four histones, which are involved in histone–histone interactions, were considered homogeneous and invariable until it became possible to resolve H2a, H2b and H3 into variants which exhibit tissue-specific variation by polyacrylamide gel electrophoresis in presence of non-ionic detergents[3] (Fig. 1). We report here on the primary structure of the variants of mammalian histones 2a, 2b and 3.

Individual histone components were isolated from calf thymus and several other mammalian tissues by preparative polyacrylamide gel electrophoresis (in the presence of Triton X-100) of fractions enriched in individual histone classes by chemical fractionation[4] or by ion exchange chromatography on CM-cellulose (S.G F. and A.Z. in preparation). Direct comparison of the amino acid compositions of the electrophoretically pure variants of the different histone classes indicated the presence of one to three amino acid substitutions in each case[5]. To determine the molecular differences between the variants in more detail, we analysed their tryptic or thermolytic peptides resolved by microfingerprinting on microcrystalline cellulose plates.

After visualisation by spraying with 10% triethylamine and 0.01% fluorescamine in acetone[6–7], the peptides (or in some cases only non-identical peptides) were eluted from the plates, hydrolysed and subjected to amino acid analysis. The position within the protein of the eluted peptides was determined by homology in amino acid composition with the published amino acid sequences for the major components of these histones in calf thymus[8–10] With the exception of the core of H3.3, no ambiguities were encountered in localising substitution sites by composition differences. The substitutions determined by these methods agree with the differences in composition found by amino acid analysis of the intact proteins.

The tryptic peptide maps of calf H2a.1 and H2a.2 were identical with the exception of one additional spot seen in H2a.2. This spot was found to be Ser-Arg (actual analysis: serine, 1.94; arginine, 1.06) arising from a serine–threonine substitution at position 16, known also to occur in the rat[11]. All other tryptic peptides from H2a.2 were homologous to H2a.1 peptides. Thermolytic digestion of the insoluble tryptic core of H2a.2 produced a peptide homologous with residues 43–51 (proline, 1.16; glycine, 2.25; alanine, 2.11; valine, 2.01; methionine, 0.53; tyrosine, 0.92) except that a methionine residue was present and leucine 51 was absent. Cleavage of H2a.2 with cyanogen bromide, isolation of the fragments by preparative polyacrylamide gel electrophoresis and amino acid analysis confirmed this methionine–leucine substitution at position 51 and the serine–threonine substitution at position 16.

Both tryptic and thermolytic peptide maps of mouse ascites H2b.1 and H2b.2 were identical. Since differences in hydrophobicity determine the resolution of histones in non-ionic detergent electrophoresis, we examined the hydrophobic regions. Peptide T12 (ref. 12) was homologous with residues 73–79 except that in H2b.2 it contained an additional serine residue and no glycine (serine, 1.79; glutamic acid, 1.39; alanine, 2.18; isoleucine, 1.05; arginine, 0.59). This indicates a serine-glycine substitution at position 75. Calf thymus and other mammalian tissues contain a minor component which migrates similarly to H2b.2 on electrophoresis. The tryptic peptide map of this minor component from calf thymus is identical to those of mouse and calf H2b.1 except that it possesses one extra spot. The composition of this spot (serine, 1.23; glutamic acid, 1.19; glycine, 0.93; alanine, 1.83; isoleucine, 0.85; arginine, 0.96) is identical with T12 (which is also present on the map) of H2b.1 yet it moves considerably farther in the electrophoretic and chromatographic dimensions. The most likely explanation for this is the substitution of a glutamine for a glutamic acid at position 76 in a new H2b variant, H2b.3. This is consistent with its amino acid composition being identical to H2b.1. The simultaneous presence of peptide T12 in two spots is probably due to partial deamidation of glutamine 76.

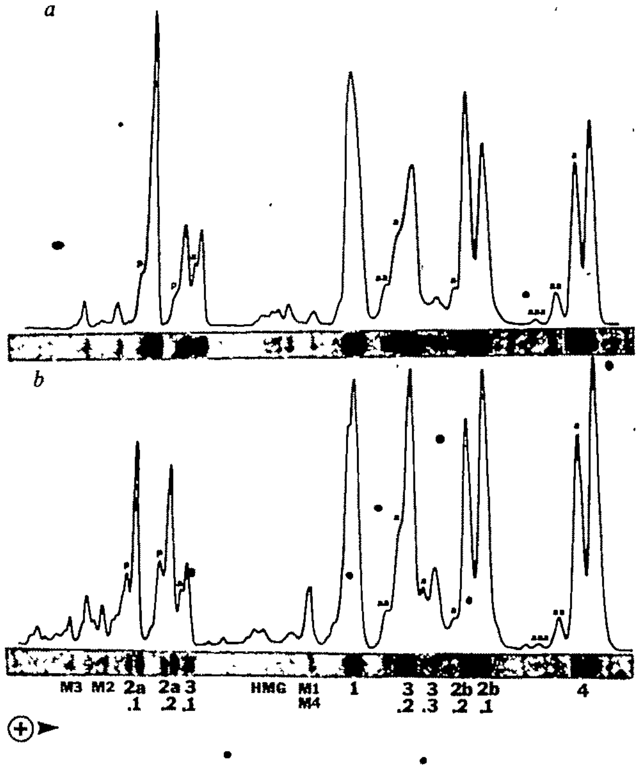

Fig. 1 Comparison of the histones of mouse thymus (*a*) and mouse liver (*b*) as resolved by electrophoresis (from left to right) on 12% polyacrylamide gels containing 7.5 M urea, 6 mM Triton X-100 and 5% acetic acid. The proteins were stained with amido black and the gel scanned at 300 nm. 1, 2a, 2b, 3, and 4 = major histone species; .1, .2, .3 = variants of a given histone species; M1, M2, M3, M4 = minor histone species with properties characteristic for histones but amino acid compositions not closely related to any of the five major histone species[13]; HMG = 'high mobility group' proteins[27]; a = acetylated, p = phosphorylated forms. Note the difference in the relative amounts of H2a.1 against H2a.2, H2b.1 against H2b.2, H3.1 against H3.2 and H3.3 in the two tissues.

Tryptic maps of calf H3.1 and H3.2 are identical but the thermolytic map of H3.2 shows a major spot in a region where H3.1 shows a cluster of faint spots. Anlaysis of the H3.2 spot revealed a peptide homologous with residues 92–99 of H3.1 except that it contained no cysteine and had one serine (serine, 0.92; glutamic acid, 3.06; alanine, 2.11; leucine, 0.93; tyrosine, 0.97). Thus a serine–cysteine substitution exists at position 96, in agreement with the findings of Patthy and Smith[13] and known to occur also in shark, carp and chicken[14–16]. From thermolytic digestion of the tryptic cores of calf and sheep H3.3 we have confirmed that it also contains the above serine–cysteine substitution. The remainder of the core peptides are homologous with the sequence of H3.1 except that we cannot find a peptide corresponding to residues 88–90 (Ala-Val-Met). Instead we recover a peptide with the composition: alanine, 1.03; isoleucine, 0.90; glycine, 1.07. The most likely substitution pattern indicated by our data would be: isoleucine instead of valine 89 and glycine instead of methionine 90 The latter substitution is not conservative and occurs rarely[18]. Pea H3, however, also contains a 'helix-breaker' (serine) at position 90 (ref. 17). The arrangement of amino acids in this region of H3.3 has to be confirmed by direct sequence studies.

Figure 2 summarises our findings for all the mammalian H2a, H2b and H3 variants which we have characterised so far. All the substitutions (except for position 16 in H2a) are located in hydrophobic regions where the 'helix probabilty'[19–20] is sensitive to small changes in amino acid side chains All but one of the substitutions are conservative and result in small changes in the detergent affinity except for the cysteine–serine substitution in H3 which has a large effect on detergent affinity. This is consistent with the observed general correlation between detergent affinity and helix probability[2,21], since, although cysteine and serine are similar in configuration, they belong to different categories of helix promoting ability[19]. Our findings for the histone variants demonstrate the extreme sensitivity of our method to small differences in hydrophobic properties of proteins, which facilitates the separation of proteins differing in a single conservative amino acid substitution involving neutral amino acid residues.

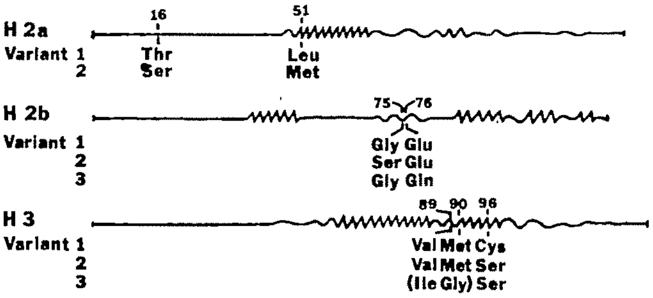

Fig. 2 Substitution sites in the mammalian histone variants. The degree of high helix probability[20] in different regions of the proteins are symbolically indicated by wavy lines

Except for H2b.2, which has only been found in the mouse[22], all variants have been found simultaneously in all tissues of all mammals examined, although in different relative amounts[23]. The simultaneous presence of all variants in plasmacytomas and tissue culture lines derived from inbred mice, indicates that the genes for the different histones are non-allelic. Furthermore, all variants are synthesised simultaneously in HeLa cells[24] from mRNAs with slightly different properties[24]. In the sea urchin, different H2a and H2b variants are synthesised at different stages of embryonic development which suggests the existence of different histone operons[25,26].

These observations, together with the parallel conservation of the non-allelic histone variants throughout the evolution of at least the mammals, suggest that the histone variants have independent essential functions. The histone classes H2a, H2b, H3 and H4 interact by non-ionic forces to form highly ordered heteropolymers which constitute the central structural element of eukaryotic chromosomes[28]. The amino acid substitutions distinguishing the histone variants are located in the hydrophobic regions which are involved in these histone–histone interactions. It is therefore conceivable that chromosomal fibres containing histone complexes composed of different histone variants differ significantly in their physical properties and that different histone variant populations are necessary for optimal function of specific regions of the genome in nuclei of cells with different metabolic patterns.

Formation of amino acids from elemental carbon by contact glow discharge electrolysis

THE formation of amino acids in various inferred prebiotic conditions has been widely studied[1,2]. Recently we reported syntheses of amino acids from aliphatic carboxylic acids and ammonia[3,4], and from aliphatic amines and formic acid[4,5] by means of contact glow discharge electrolysis (CGDE)[6]. We describe here the formation of amino acids and urea from elemental carbon in the presence of aqueous ammonia by CGDE. By this reaction and the following process, the elemental carbon of the elctrode was converted into the bio-organic compounds.

The reaction tube used for CGDE was as illustrated in Fig. 1. The carbon rod (Irikawa, IBGC-55; diameter 5 mm; specific gravity 1.65, electrical resistance 250 Ω) was used as the anode and platinum wire was used as the cathode. All glassware used was heated for 1 h at 500 °C before CGDE to eliminate possible contamination of amino acids[7] Anhydrous ammonia was bubbled into the twice-distilled water (about 10 ml) in the reaction tube and then CGDE was performed for 35 min. The applied electric current was 60 mA at 600–1200 V. CGDE was conducted in conditions of ammonia gas saturation and the reaction temperature was kept at about 30 °C by cooling the reaction tube in a methanol–dry ice bath After the reaction was over, the solution was heated at 90 °C for 23 h in a sealed tube and was evaporated to almost dryness under reduced pressure. The residue was hydrolysed with 2 ml of distilled 6 N hydrochloric acid in a sealed tube under reduced pressure After heating at 120–130 °C for 23 h, the sealed tube was opened and the mixture evaporated to dryness under reduced pressure The residue in the tube was diluted appropriately and was analysed by an amino acid analyser (Yanagimoto LC-5S).

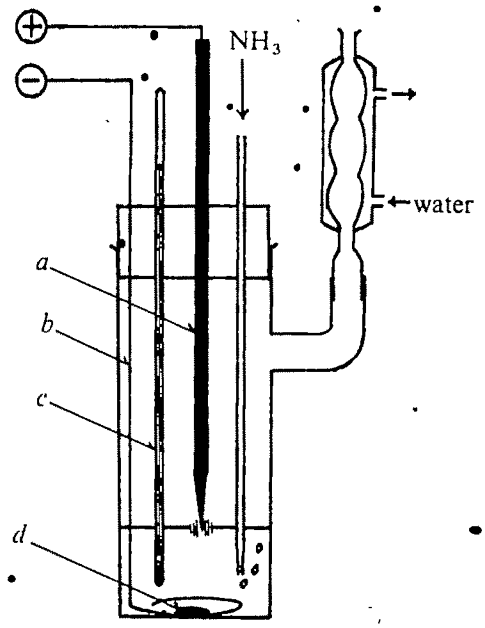

Fig. 1 Reaction tube for CGDE, *a*, carbon anode; *b*, platinum cathode; *c*, thermometer; *d*, magnetic stirrer bar

A typical result of the amino acid analysis is shown in Fig. 2*B*. Several control experiments were carried out without applying CGDE, and only trace amounts of glycine were detected (Fig. 2*A*). The weight loss of the carbon anode after the CGDE reaction was 5.6 mg. Thus the conversion of elemental carbon to organic carbon was at least 0.2% (during CGDE a very small amount of carbon

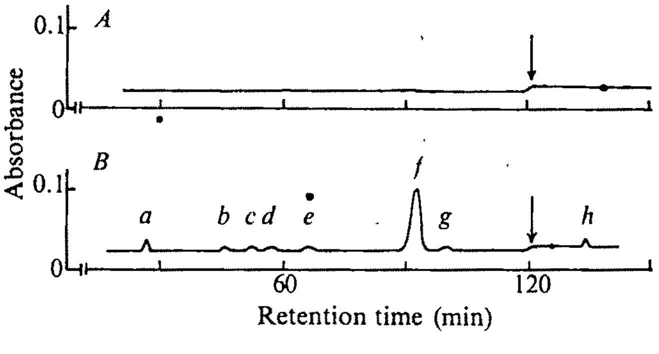

Fig. 2 Amino acid analysis *A* Control experiment without CGDE A trace amount of glycine (~10^{-10} mol) was detected The peak is not visible in the chart *A*. *B*, Reaction conditions were: electric current, 60 mA, reaction time 35 min Compounds found in the reaction mixture were *a*, urea (6 1 × 10^{-7} mol); *b*, aspartic acid (1 × 10^{-9} mol), *c*, threonine (1 × 10^{-9} mol), *d*, serine (8 × 10^{-10} mol), *e*, glutamic acid (5 × 10^{-10} mol), *f*, glycine (4 5 × 10^{-8} mol); *g*, alanine (1 × 10^{-9} mol); *h*, unknown peak Arrows indicate buffer change.

powder was found in the reaction mixture, so 0.2% is the minimum).

To our knowledge, this reaction is the first example in which amino acids and urea were obtained directly from elemental carbon These facts suggest a new possibility for the prebiotic synthesis of amino acids in prebiotic conditions on the primordial Earth.

Enzyme hydration may explain catalytic efficiency differences among lactate dehydrogenase homologues

HOMOLOGOUS enzymes of species with different cell temperatures usually display temperature-adaptive differences in their catalytic properties[1–7]. Thus enzymes of low cell temperature species characteristically exhibit higher specific activities and lower activation free energies and enthalpies than the homologous enzymes of high cell temperature species[2–7]. For lactate dehydrogenase (LDH, E.C.1.1.1.27; lactate: NAD$^+$ oxidoreductase), a single M_4 (muscle type) LDH molecule from a cold-water fish can catalyse the conversion of pyruvate to lactate three times as rapidly at 5 °C as an M_4-LDH from a mammal[5]. In this paper we present evidence that these temperature-compensating differences in catalytic efficiency may derive in part from different amounts of exergonic hydration of the enzymes during the activation step in catalysis. Lowering the activation free energy ($\Delta G\ddagger$) 'barriers' to enzymic reactions by way of the reversible hydration of amino acid side chains and/or polar peptide linkages permits the adjustment of catalytic efficiencies without necessitating the modification of amino acid sequences in the active sites of the enzymes.

Attempts to explain mechanistically the differences in catalytic efficiency which exist among homologous forms of the same enzyme must face the following paradox: even though different homologues vary significantly in catalytic efficiency, the amino acid sequences of their active (catalytic) sites are virtually identical[8–10]. Where amino acid substitutions in active sites have occurred, they tend to be extremely conservative[8]. It therefore seemed reasonable to consider non-active site regions of the enzyme when attempting to explain the differences in catalytic efficiency among differently temperature-adapted LDH homologues.

Recently a rate-enhancement mechanism which is not based on active site conformations has been proposed, the 'protein group transfer–hydration mechanism'[11]. Rate enhancement by this mechanism results from the exergonic transfer of protein groups (amino acid side chains and peptide backbone linkages) between the hydrophobic interior of the enzyme and the enzyme–water interface during the activation step in catalysis. These exergonic transfers will lower the free energy of the activated complex, thereby enhancing its probability of formation and accelerating the reaction rate. For example, the transfer of a peptide linkage from the interior of the enzyme, where it is relatively or fully dehydrated, to the enzyme–water interface, where a strongly exergonic hydration of the group will occur, can lower $\Delta G\ddagger$ by as much as 1,100 cal mol^{-1} (ref. 11). Since changes in $\Delta G\ddagger$ of only 100–200 cal mol^{-1} are adequate to approximately double the rate of a reaction[2], even slight changes in the exposure (hydration) of protein groups could be sufficient to significantly modify the catalytic efficiency of an enzyme. Since conformational changes seem to have a generally important role in enzymic catalysis[12], numerous changes in protein group exposure to water will occur during the activation event Thus the protein group transfer–hydration mechanism of rate enhancement seems a generally accessible mechanism for rate enhancement of all types of enzymes.

In the present study we have tried to determine if different amounts of exergonic hydration processes during the activation step occur in the LDHs of warm- and cold-blooded vertebrates. Three experimental tests, all of which are based on the energy and volume changes which accompany protein group transfer–hydration processes, were carried out.

First, the transfer of all types of protein groups from a relatively non-polar environment, such as the enzyme interior, to water occurs with a volume decrease arising from the dense organisation of water around the hydrated protein group[13]. Thus a rough estimate of the involvement of protein group transfer–hydration processes in catalysis can be obtained from the volume change which occurs during the activation event. The activation volume ($\Delta V\ddagger$) equals the difference in system (enzyme plus solvent) volume between the ground-state enzyme–substrate complex and the activated complex[14]. The activation volume of a reaction can be determined by estimating the effect of hydrostatic pressure on the maximal velocity (V_{max}) of the reaction[14]. If the highly efficient LDHs of low cell temperature organisms become more hydrated during the activation step

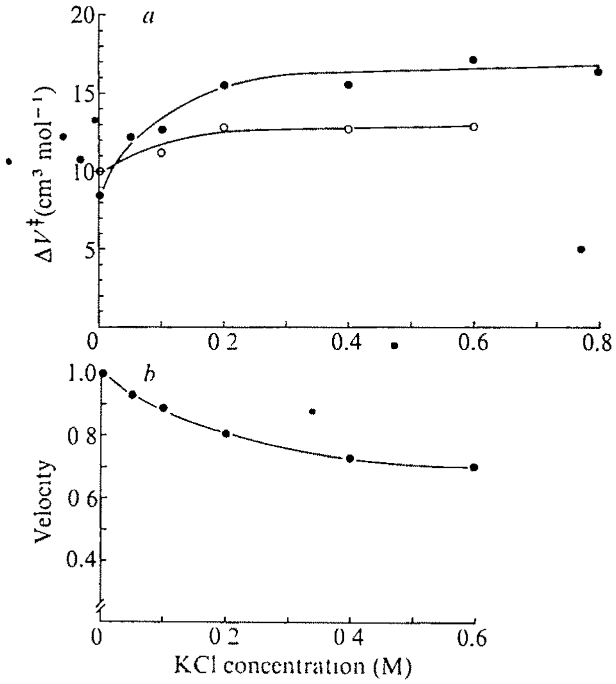

Fig. 1 *a*, Effect of KCl concentration on $\Delta V\ddagger$ of the halibut (●) and turkey LDH reactions (○). *b*, Effect of KCl concentration on V_{max} of the halibut LDH reaction. All assays were carried out using fully purified LDHs (Dr Nathan O. Kaplan). The assay medium contained, in a total volume of 5.0 ml, 80 mM Tris-HCl buffer (*p*H 7.5 at the assay temperature, 10 °C), 0 025 mM NADH, varying concentrations of pyruvate and KCl, and enzyme, which was added last to initiate the reaction The change in A_{340} was followed with time. The high pressure assay system was as described by Low and Somero[11,13]. The inhibition data were obtained from assays run at 1 atm Theoretical V_{max} values were determined using several pyruvate concentrations; data were analysed using plots of 1/velocity against 1/pyruvate concentration. For determining activation volumes the reactions were run at 1,000 and 5,000 pounds per square inch (68 and 340 atm, respectively). The logarithm of V_{max} for the different LDHs varied linearly with pressure over the pressure range of 1 to approximately 500 atm.

than the LDHs of birds and mammals, then a larger negative contribution to $\Delta V\ddagger$ will be found for the cold-adapted enzymes.

A second experimental test of this hypothesis is provided by the fact that the free energy changes which accompany these transfer processes are strongly influenced by the salt composition and concentration of the medium[15]. Salt conditions which make these transfers less exergonic would be expected to have two measurable effects. First, the velocity of the reaction will be reduced since the transfer will be energetically less favourable. Second, by impeding the hydration of transferred protein groups, salts will increase $\Delta V\ddagger$. Thus a comparative estimate of the parts played by protein group transfer–hydration processes can be obtained by measuring salt effects on V_{max} and $\Delta V\ddagger$. If these transfer processes are responsible for the higher specific activity of LDHs of low cell temperature species, then the salt sensitivities of V_{max} and $\Delta V\ddagger$ should be greater for the cold-adapted enzymes.

A third approach to analysing the parts played by these transfer–hydration processes in LDH homologues is based on the fact that these transfers occur with substantial enthalpy changes[16,17]. Also, as in the case of transfer free energies and volumes, transfer enthalpies will be affected by solute conditions[18]. Thus, if protein group transfers contribute also to the low $\Delta H\ddagger$ values of enzymes of cold-adapted organisms, then the $\Delta H\ddagger$ values of cold-adapted LDHs should be more salt-sensitive than the values of avian and mammalian LDHs.

The data presented in Figs 1 and 2 and in Table 1 support all of the predictions made above. Figure 1 illustrates the manner in which a weakly salting-out salt, KCl, affects the $\Delta V\ddagger$ and V_{max} of the LDH reactions. Increasing KCl concentrations titrate both the rate and $\Delta V\ddagger$, with essentially complete titration occurring at KCl concentrations of approximately 0.2–0.4 M. The V_{max} and $\Delta V\ddagger$ values of the halibut reaction are significantly more salt-sensitive than the values for the turkey LDH reaction (Fig. 1, Table 1), the result predicted on the basis of a greater degree of exergonic exposure and hydration of protein groups during the activation step in the halibut LDH reaction.

Table 1 lists the effects of 0.6 M KCl on V_{max} and $\Delta V\ddagger$ for LDH reactions of several warm- and cold-blooded species. The highly efficient teleost fish LDHs are significantly more inhibited than the other LDHs, and the salt-induced increase in $\Delta V\ddagger$ is also largest for the teleost enzymes. The shark LDH is intermediate in salt sensitivity between the teleost and avian–mammalian enzymes. Elasmobranch LDHs are also intermediate between teleost and avian–mammalian LDHs in catalytic efficiency[19].

Figure 2 illustrates the effects of 0.6 M KCl on the $\Delta H\ddagger$ values of the halibut and turkey LDH reactions. KCl has virtually no effect on the $\Delta H\ddagger$ of the turkey LDH reaction. $\Delta H\ddagger$ values of 10,600 and 10,200 cal mol^{-1} were observed in the absence and presence, respectively, of KCl. For the halibut reaction, addition of 0.6 M KCl to the assay medium increased $\Delta H\ddagger$ from 7,520 cal mol^{-1} to 9,260 cal mol^{-1}. Only approximately 2 cal mol^{-1} of this increase are due to changes in pressure–volume work ($\Delta H\ddagger = \Delta E\ddagger + P\Delta V\ddagger$) arising from the salt-induced increase in $\Delta V\ddagger$ (Table 1, Fig. 1). The Arrhenius plot for the halibut LDH reaction in the presence of 0.6 M KCl displays a 'break' near 25 °C. This discontinuity in slope may be the result of a salt-induced change in enzyme structure at higher temperatures.

The finding that the size of $\Delta V\ddagger$ at 0.6 M KCl is greatest for the teleost LDHs (Table 1) may be of importance in understanding the structural differences which exist among the LDHs. The $\Delta V\ddagger$ observed at KCl concentrations between approximately 0.2 and 1.0 M may be a rough measure of the change in protein void volume which arises from alterations in the packing efficiency of amino acid residues during the activation event[13]. That is, this KCl-insensitive component of $\Delta V\ddagger$ is a 'structural' activation volume as distinct from the 'hydration density' component of $\Delta V\ddagger$, which is due to water organisation around transferred protein groups and which is titrated by low KCl concentrations[13]. Within this conceptual framework the larger $\Delta V\ddagger$ at high salt concentration found for the teleost LDHs is interpreted as being due to a greater degree of enzyme unfolding during catalysis. This increased expansion of enzyme structure during catalysis by the teleost LDHs may be possible because of the smaller amounts of secondary structure in these enzymes relative to the LDHs of birds, mammals and elasmobranchs[19]. Thus, the more flexible LDHs of cold-adapted species may be capable of more fully unfolding their conformations to expose protein groups during catalysis. This interpretation is consistent with the finding that the thermal stabilities of enzymes are frequently inversely proportional to their catalytic efficiencies[3,4].

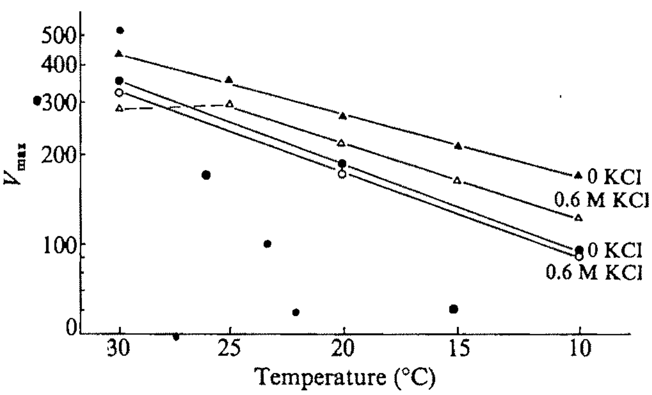

Fig. 2 Arrhenius plots showing the effect of 0.6 M KCl on the activation enthalpy value of the halibut (triangles) and turkey LDH reactions (circles). Assay conditions were as given in Fig. 1. Theoretical V_{max} values were determined using several concentrations of pyruvate. ▲, zero KCl; △, 0.6 M KCl; ●, zero KCl; ○, 0.6 M KCl.

In summary, the apparent necessity for maintaining the same amino acid sequences in both the binding and catalytic loop

Table 1 Effects of 0.6 M KCl on $\Delta V\ddagger$ and V_{max} for LDHs from warm- and cold-blooded organisms

Species	$\Delta V\ddagger$, no KCl*	$\Delta V\ddagger$, 0.6 M KCl*	600–0*	% Inhibition
Rabbit	9.9±0.7 (3)	12.3±0.5 (3)	2.4	11
Turkey	10.0±1.4 (6)	12.9±1.4 (6)	2.9	5
Shark (*Carcharodon carcharias*)	7.8±1.3 (7)	14.2±1.3 (6)	6.4	9

Halibut (*Hippoglossus stenolepis*)	8.5±0.9 (4)	16.0±1.4 (11)	7.5	29
Haddock (*Melanogrammus aeglefinus*)	8.4±1.4 (5)	17.2±2.3 (3)	8.8	20

*Unit: cm^3 mol^{-1}. Mean ±1 s.d. (sample size) for columns headed no KCl and 0.6 M KCl.

†Inhibition of V_{max} due to addition of 0.6 M KCl to the assay medium. Theoretical V_{max} values were determined using several pyruvate concentrations; data were analysed using plots of 1/velocity against 1/pyruvate concentration. Theoretical V_{max} values were used because KCl inhibited the reaction competitively as well as non-competitively.

regions of all homologues of M_4-LDH (ref. 8) does not hinder the functional adaptation of each LDH to the temperature conditions it experiences. For the LDHs of low cell temperature species, which must function at low and, in many cases, highly variable temperatures, adaptive reductions in $\Delta G\ddagger$ and $\Delta H\ddagger$ seem to have been achieved by means of increased exergonic exposures of hydrophilic protein groups during the activation step in catalysis. Thus, a higher catalytic efficiency (lower $\Delta G\ddagger$) and a reduced temperature dependency (lower $\Delta H\ddagger$) can both be achieved by evolutionary changes in enzyme structure at regions remote from the active site.
